Fig. 1 *a*, Simplified paternal pedigree of XX males X-1, X-2 and X-3 (black squares) (from ref. 8). *b*, *c*, Hybridization of *Taq*I-digested DNAs from the XX males and their relatives with 50f2 (*b*) and 47c (*c*). Each lane corresponds to the individual immediately above that lane in the pedigree shown in *a*. DNA samples were digested with *Taq*I, electrophoresed on agarose gels, transferred[14] to Pall Biodyne (1.2-μm pores) nylon paper and hybridized with radiolabelled probes largely as described previously[13]. However, following transfer, the air-dried papers (DNA-coated side up) were exposed to germicidal (short-wave) ultraviolet light at an intensity of 400 μW cm^{-2} for 1 min; they were not baked. The arrows on the left indicate the Y-specific *Taq*I fragments detected. The sizes of restriction fragments (in kilobase pairs) are shown on the right.

Table 1 Y-specific DNA sequences in XX males and their relatives

	Probes							
Individual	47c	50f2	52d	118	27	49f	12f3	pDP34*
Normal male	2	4	3	8	1	3	1	1
Normal female	0	0	0	0	0	0	0	0
IX-1 (GM2672) father	2	4	3	ND	ND	ND	ND	1
IX-2 (GM2671) mother	0	0	0	ND	ND	ND	ND	0
X-1 (GM2626) XX male	2	0	0	0	0	0	0	0
IX-3 (GM2624) father	2	4	3	ND	ND	ND	ND	1
IX-4 (GM2625) mother	0	0	0	ND	ND	ND	ND	0
X-2 (GM2670) XX male	2	0	0	0	0	0	0	0
IX-5 (LGL118) father	2	4	3	ND	ND	ND	ND	1
IX-6 (LGL117) mother	0	0	0	ND	ND	ND	ND	0
X-3 (LGL115) XX male	2	2	2	4	0	0	0	0
X-4 (LGL116) brother	2	4	3	ND	ND	ND	ND	1
X-5 (LGL119) sister	0	0	0	ND	ND	ND	ND	0

Genomic DNAs from normal unrelated males and females and from the indicated members of the pedigree in Fig. 1*a* were digested with *Taq*I, blotted and hybridized with probes detecting Y-specific sequences. Methods were as described for Fig. 1*b*, *c*. The number of male-specific *Taq*I fragments detected by each probe are shown. ND, not done.

* The data for probe pDP34 (*DXYS1*) are from ref. 13.

of our finding of a sporadic XX male who expresses his father's allele for 12E7, a Y-linked marker, but fails to express his father's *Xg* allele[5]. Both cases can be explained by an interchange of a portion of the Y chromosome with a portion of the paternal X chromosome[2]. However, such an interchange cannot easily account for XX males X-3's apparent failure to express his father's allele for the dominant, X-linked marker *Xm* (ref. 1), which maps to the long arm of the X chromosome[18]; *Xg* maps to the short arm. It is possible that the Xm typing of this family was in error. Unfortunately, as Xm antiserum is no longer available, the typing cannot be repeated.

Taken together, our findings and those of Guellaen *et al.*[6] suggest that, though variable in size, the segment of the Y chromosome present is similar in at least some familial and sporadic XX males. It is likely that that segment of the Y chromosome carries the genetic information which is male-determining.

This study was aided by grants from the NIH, the Sigrid Jusélius Foundation, the Folkhalsan Institute of Genetics and the Academy of Finland. We thank Laura Brown for assistance, George Church for technical advice, and David Botstein, in whose laboratory some of these experiments were performed.

X-linkage of steroid sulphatase in the mouse is evidence for a functional Y-linked allele

Elisabeth Keitges, Martha Rivest, Marcello Siniscalco* & Stanley M. Gartler

The Center for Inherited Diseases, Departments of Medicine and Genetics, SK-50, University of Washington, Seattle, Washington 98195, USA
* Memorial Sloan-Kettering Cancer Center and Department of Cell Biology and Genetics, Sloan-Kettering Division, Graduate School of Medical Sciences, Cornell University, New York, New York 10021, USA

In the human there is an X-linked gene affecting steroid sulphatase (STS) activity which, when deficient, is associated with X-linked congenital ichthyosis[1,2]. The gene (*STS*) is located on the distal tip of the short arm[3–6] and is only partially inactivated when it is on the inactive X-chromosome[7–10]. In the mouse, the genetics of *STS* are not clear; the results of one study using XX:X0 oocyte comparisons indicated X-linkage[11], but three other studies using STS variants have produced segregation data compatible with autosomal linkage of murine *STS*[12–14]. Here we present the results of STS assays of crosses of deficient C3H/An male mice[12] to normal X0 animals which demonstrate X-linkage of *STS* in the mouse and indirectly indicate the existence of a functional *STS* allele on the Y-chromosome which undergoes obligatory recombination during meiosis with the X-linked allele.

Table 1 Results of crosses of STS-deficient C3H/An with normal mice

Cross		No. of offspring			
		Females		Males	
Female	Male	STS$^+$	STS$^-$	STS$^+$	STS$^-$
*C3H/An (STS$^-$)	BALB/c (STS$^+$)	13	0	17	0
*BALB/c (STS$^+$)	C3H/An (STS$^-$)	6	0	8	0
*C3H/An (STS$^-$)	Feral mouse (STS$^+$)	3	0	5	0
*C3H/An (STS$^-$)	C57B (STS$^+$)	Not tested		7	0
*(C3H/An × C57B) F_1 (STS$^+$)	C3H/An (STS$^-$)	10	13	13	15
*(C3H/An × C57B) F_1 (STS$^+$)	C57B (STS$^+$)	16	0	17	0
C3H/An (STS$^-$)	(C3H/An × BALB/c) F_1 (STS$^+$)	2	6	2	4
C3H/An (STS$^-$)	(BALB/c × C3H/An) F_1 (STS$^+$)	1	6	2	1

STS assays were carried out on sonicated spleen extracts using ^{3}H-dehydroepiandrosterone sulphate as substrate, according to Shapiro *et al.*[32]. Pure-breeding STS$^+$ mice have STS activity of >250 pmol per h per mg protein and pure-breeding STS$^-$ mice (C3H/An) have <7 pmol per h per mg protein. The STS activity of STS$^+$ hybrid mice varied from 70 to 160 pmol per h per mg protein.
* Unpublished data from Balazs *et al.*[12].

When C3H/An STS-deficient mice are crossed with STS normal animals in various combinations, the results seem compatible with simple autosomal inheritance of STS deficiency (Table 1). However, one litter from a cross of an STS-deficient female with a supposed pure-breeding STS normal male yielded one STS-deficient female. If the exceptional female was X0, it would suggest that STS deficiency follows an unusual form of sex-linked inheritance. Unfortunately, materials were not available for cytological analysis of the exceptional animal nor could the male parent be tested for possible heterozygosity.

We therefore instituted crosses of C3H/An STS-deficient males with STS normal X0 mice marked with the tabby (*Ta*) gene. The X-linked tabby marker permits separation of mice carrying *Ta*, in either the hemizygous or homozygous condition, from heterozygotes and wild-type mice by its characteristic coat markings. From these crosses, three classes of offspring are expected with regard to tabby and sex: *Ta*/+♀♀, +/0♀♀ and *Ta*/Y♂♂. Table 2 gives the results of these crosses with respect to tabby, sex and STS level. If the STS variant we are studying is autosomal, there should be no differences in STS levels between the three classes of offspring. On the other hand, if the STS variant lies on the X-chromosome, then the X0 progeny should be STS-deficient, in contrast to the normal or intermediate values for the *Ta*/+ and *Ta*/Y animals. In fact, the X0 animals show STS values not significantly different from their deficient male parent. The absence of STS-deficient animals among 15 *Ta*/Y and *Ta*/+ siblings argues against the possibility that the X0 parents are heterozygous for STS deficiency at an autosomal locus. These results demonstrate X-linkage of the C3H/An STS deficiency.

The studies reported here (Table 1) and elsewhere[12] using the C3H/An STS-deficient mouse strain in various crosses yield results compatible with simple autosomal inheritance of the deficient *STS* gene in the C3H/An strain. However, when deficient C3H/An males are crossed to STS normal X0 mice, the segregation pattern observed in the offspring demonstrates X-linkage of the *STS* deficient gene (Table 2). These apparently contradictory results are best explained by postulating a functional Y-linked *STS* gene that undergoes obligatory recombination with its X-linked allele. As both the C3H/An and BALB/c Y chromosomes exhibit recombination with the X-linked *STS*

Table 2 Levels of STS activity resulting from crosses of STS^+ X0 to STS^- XY mice

	STS activity (pmol per h per mg protein)				
	Parents		Offspring		
	STS^+	STS^{-*}			
Sex chromosomes:	X0	XY	X0†	XX	XY

	198	25	27	310	189
	119	42	23	260	188
	217	52	36	162	236
	281		62	274	176
	198		16	114	234
	162		10	244	140
	134				131
					313
					258
Mean STS value	187	40	29	227	207

Each STS value represents an individual mouse. Tabby X0 mice (F_1 mice from C57BL/6J×CBA/Ca crosses) were obtained from Jackson Laboratories (Bar Harbor, Maine). The STS assay is a modification of the technique of McNaught and France[33]. Ear punches of 2 mm diameter were placed in 100 μl of buffer (0.1 M Tris-HCl *p*H 7.2) and frozen on dry ice. The samples were then thawed and sonicated on ice for 5 s at 250 W and placed on ice. This cycle was repeated four more times. 'Cold' oestrone sulphate (4 ng) and ^{3}H-oestrone sulphate (2 μCi, specific activity 52.5 Ci mmol^{-1}; NEN) were added to 50 μl of the extract on ice. A zero-time sample of 26 μl of the assay mixture was added to 25 μl of 0.1 M NaOH. The rest of the reaction mixture was incubated at 37 °C for 40 min, then the reaction was stopped by adding 25 μl of 0.1 M NaOH. Petroleum ether (350 μl) was added to each sample and the mixtures vortexed for 30 s. The samples were placed on dry ice and an aliquot (100 μl) of the organic phase was removed and added directly to 5 ml of toluene/Omnifluor for radioisotope counting. Protein assays were done according to the Lowry method[34].

* The values reported here are for the three STS^- males used in the above crosses. All STS^- mice (C3H/An) have low STS levels which do not overlap with those of either the pure-breeding STS^+ strain or the F_1 animals. Duplicate assays varied by <10%.

† One X0 offspring was examined cytologically and the modal chromosome count was found to be 39.

Y-linked *STS* gene. However, another closely linked gene, gene (Table 1, crosses shown in lines 7 and 8) the recombinational property postulated here is not a unique characteristic of the C3H/An strain.

Ultrastructural studies of crossing-over in the XY pair of various mammals, including the mouse[15], suggest that there is partial synapsis of the X and Y, followed by chiasma formation. A model including a single obligatory crossover between the X and Y[16–18] would predict that genes distal to the crossover will be transmitted to both male and female offspring and appear to be autosomally inherited. The *Sxr* ('sex-reversed') mouse[19] is a precedent for this possibility since the *Sxr* rearrangement is passed equally to male and female offspring[20,21]. *Sxr* has been mapped to the distal tip of the X and Y coincident with the proposed X-Y pairing region of the mouse. Accordingly, the *STS* locus should map to the same region. It should be pointed out that our data on the *STS* locus in the mouse directly contradict the theory of Ashley[22], who suggests that synapsis between the X and Y chromosomes is non-homologous and that regular crossing-over does not occur between the X and Y chromosomes.

In man, the X-linked *STS* locus maps to the distal tip of the short arm of the X, which is the presumed pairing region of the human sex chromosomes[3–6]. The X-linked recessive pattern of inheritance of human STS deficiency precludes a functional *MIC2*, which codes for the red blood cell antigen 12E7, does have an expressible allele on the Y chromosome in human[23]. Obligatory recombination proximal to this locus appears to be precluded by results from studies of a polymorphism of 12E7 which shows a complex sex-limited expression of variation in 12E7 levels[24]. Therefore, if there is an obligatory crossover between the human X and Y, it would have to be distal to 12E7 and *STS*. These observations do not exclude the possibility of occasional exchange between the X and Y in human, which has been shown to occur in the origin of some XX males[25–30].

With functional alleles on the X and the Y chromosomes in the mouse, dosage compensation is not required to effect equality of expression of X-linked alleles in females and males[31]. In fact, the similarity of STS values in X0 STS^+ parents and XX STS^+ daughters seems to exclude the *STS* locus from X-inactivation. We know from coat colour markings that the tabby gene in the XX daughters is being randomly inactivated; if the *STS* locus followed the same pattern, then the STS values of the XX daughters would be approximately half those of the X0 mothers (Table 2). Definitive evidence for or against X-inactivation of the *STS* locus will require some form of cloning study in heterozygotes.

Thus, we have shown by crossing STS normal X0 mice with C3H/An STS-deficient males, that the STS deficiency of the C3H/An mice is controlled by an X-linked gene. This result, in conjunction with previous data suggesting autosomal inheritance of the C3H deficiency, implies the existence of an *STS* allele on the Y chromosome that undergoes obligatory recombination.

Does interocular transfer occur in visual navigation by ants?

Rüdiger Wehner & Martin Müller

Department of Zoology, University of Zurich, Winterthurerstrasse 190, CH-8057 Zurich, Switzerland

If an animal that learns to respond to a visual stimulus presented to only one eye can continue to respond accurately when the stimulus is presented to the other eye, it is said to exhibit interocular transfer (IOT). IOT has been studied extensively in many groups of vertebrates[1–11], but there is only one conclusive report of IOT in an invertebrate (*Octopus*)[12]. Here we demonstrate that an insect, the desert ant *Cataglyphis*, exhibits IOT when it navigates by the pattern of polarized light in the sky, but shows no IOT when it uses landmarks for orientation. This marked difference in behavioural performance may help to elucidate the neural strategies adopted by insects when using celestial (polarization) and terrestrial cues for navigation.

Insects possess multi-faceted compound eyes which endow them with full panoramic vision[13,14]. The present experiments used the long-legged Saharan desert ant, *Cataglyphis fortis*, in which the visual fields of the two eyes cover 93% of the unit sphere[15]. As the remaining 7% of 'dead space' is confined completely to parts of the unit sphere that lie below the horizon, desert ants can view simultaneously all parts of the celestial hemisphere as well as the entire skyline extending above the horizon. Ants use visual skymarks such as the Sun and the extensive pattern of polarization as directional cues[16]. A desert ant can easily be trained to find an artificial food source established, say, 20 m to the north of its underground colony[17]. Having arrived there, the ant will grasp the piece of bait (say, a small cube of cheese) with its mandibles and run home along a straight path, selecting the proper home direction (in this case south) even if the insect is displaced to unknown territory and prevented from viewing either landmarks or the Sun; the celestial pattern of polarization suffices as a compass cue[17].

To test IOT, we trained ants after covering one of the compound eyes (and its three ocelli) with a light-tight cap. Thus, these ants had to learn their home direction using only one eye (the 'trained eye'). After training was completed (Fig. 1, test A), we removed the cap from the 'naive eye' and occluded the other (trained) eye. The eye caps could be removed carefully using fine forceps, without damaging the corneal surfaces of the eyes. In scanning micrographs, eyes from which caps had been removed could not be distinguished from untreated eyes. Ants with the eye caps exchanged oriented in the homeward direction just as the controls did using their trained eyes (Fig. 1, test B1).

In these tests, the ants used both eyes to navigate until we started to train them to an artificial food source; only then was one eye occluded. In the following experiment, one eye was covered before the ant could acquire any visual information. This was done by rearing the ants in a laboratory colony and providing them with eye caps shortly after they had hatched from their pupal cases. The monocular ants were then transferred to a natural colony in the desert, where they remained underground until they began their foraging lives about 28 days later[18]. These animals were still able to perform IOT when the trained eye was covered and the naive eye opened for the first time in the ant's life, using only the pattern of polarized light in the sky (Fig. 1, test B2).

In contrast, if the ants used landmarks to pinpoint the position of their nest, IOT did not occur. This was demonstrated by marking the position of the nest by a set of artificial landmarks, consisting of three black cylinders (11° high and 6° wide), which were positioned at the corners of an equilateral triangle centred on the nest entrance (Fig. 2*a*). Ants were tested which had already returned from the food source to the nest; such ants have reset their path integration (celestial navigation) system to zero and rely exclusively on landmarks for finally locating the

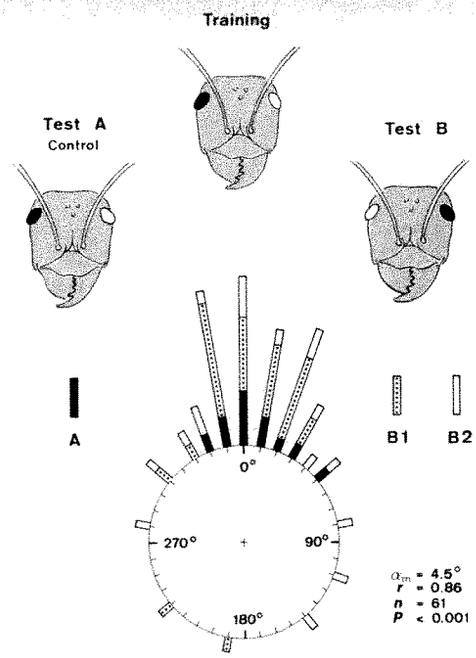

Fig. 1 Ants exhibit interocular transfer of visual information deduced from the pattern of polarized light in the sky. The bars indicate walking directions of monocular ants which can see only the pattern of polarized light in the sky. Landmarks and the Sun were occluded[17]. One eye was covered with a thin coat of fast-drying paint (Testors Matte Enamel 1149 Black) applied while the ant was immobilized, its head viewed through a dissecting microscope. 0°, Homeward direction. A, Control experiment: trained eye open; $n = 11$. B, Tests for interocular transfer: naive eye open. The naive eye was occluded while training the ant to the 0° compass course (B1; $n = 32$) or during the entire lifetime of the ant before the experiment (B2; $n = 18$). α_m and r are the direction and length of mean orientation vector, respectively[25]. If one eye is occluded, ants, as well as other arthropods, deviate by an error angle towards the seeing side. In *C. fortis*, this error angle, ε, was determined before the experiment ($\varepsilon = 37.2 \pm 4.3°$ (±s.e.), $n = 50$) and then used to correct the ants' compass bearings. In all tests, homeward orientation was highly significant ($P < 0.001$; Rayleigh test[25]).

position of their nest[16]. The distance between the nest entrance and each cylinder was 2 m.

Monocular ants learned the configuration of landmarks while performing four to six orientation runs which led them to a distance of up to 3 m from the nest; only then did they begin foraging up to distances of more than 50 m. In the critical test, ants and landmarks were transferred to a nearby plain which had been provided with a grid of white lines to facilitate the recording of the ant's walking trajectories[17]. When the ants captured directly at the nest entrance were released anywhere near the triangle of cylinders, they immediately headed for the centre of the triangle and consistently searched there by walking in narrow loops around the point where they expected the nest to be (Fig. 2*b*, *c*). In contrast, when the trained eye was occluded and the naive eye opened, the ant was unable to locate the centre of the triangle to which it had been trained, but searched around the point where it was released (Fig. 2*d*). However, if the eye cap was immediately exchanged, leaving the trained eye open and the naive eye occluded, the ant again oriented perfectly by searching the centre of the triangle (Fig. 2*b*, *c*). Even when eye caps were changed from eye to eye several times, the same result was always obtained; the ant oriented perfectly when using the trained eye, but was disoriented completely when using the naive eye.

It may generally be assumed that IOT for some function occurs when the locus of that function is downstream from the place where information from the two eyes is combined. Lack of IOT would indicate some contribution from monocular mechanisms peripheral to binocular convergence. The landmark experiments indicate that the way in which the image of the

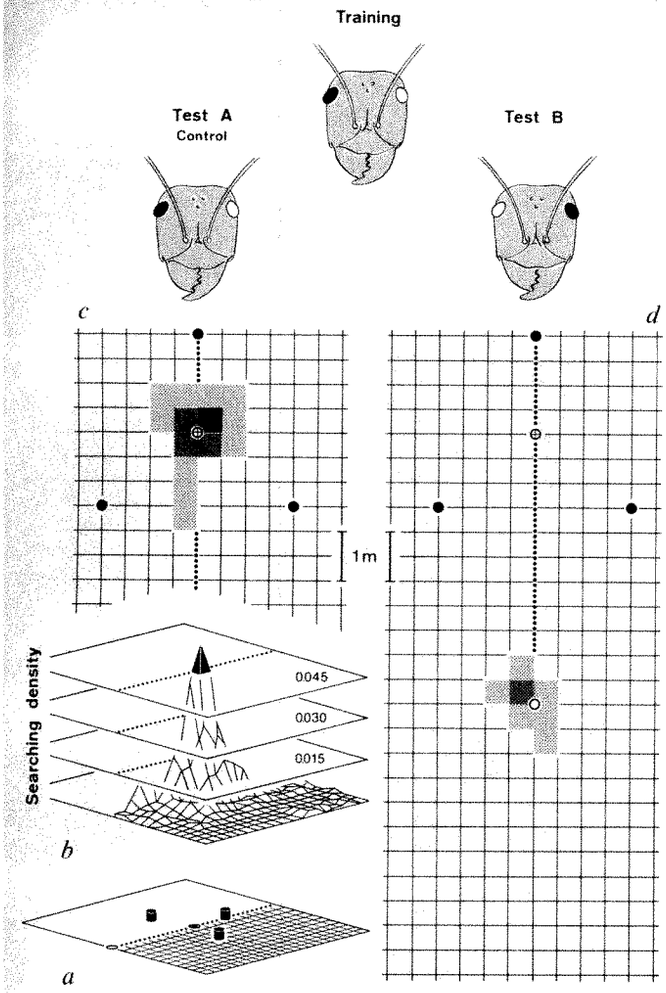

Fig. 2 Ants do not exhibit interocular transfer of visual information deduced from landmarks. *a*, Landmark configuration. Monocular ants were trained to the centre ⊕ of the triangle marked by three black cylinders (11° high, 6° wide as seen from the centre of the triangle). In the tests following the training procedure, the ants were released outside the triangle (at ○). *b*, *c*, Test A, control experiment; trained eye open. Searching densities (*SD*) are shown in three-dimensional (*b*) and two-dimensional (*c*) plots. They were determined as follows. In the field, the ants' paths were recorded at reduced scale by using a grid of white lines painted on the hard desert ground. Later, for each of the sampling squares, the total pathlengths of all ants tested were determined by using an electronic digitizer, and the relative pathlengths per sampling square (searching densities) were computed. In *c*, *d*, the shaded areas are those that were searched by the ants most extensively: $SD > 0.045$, $0.045 > SD > 0.03$, $0.03 > SD > 0.015$. *d*, Test B, test for interocular transfer; naive eye open. The ants no longer recognized the configuration of landmarks. They searched about the point of release, but not in the centre of the triangle. In total, 30 ants were tested for 5 min each.

skyline is stored within the ant's visual system depends crucially on the information gained by each eye. A monocular ant, while turning around and scanning the entire skyline with one of its eyes, does not use the landmark information it obtains to form a central 'binocular' image that could be read and used by the other eye as well. This is consistent with the recent view that insects use internally stored images of landmarks to guide them home[19,20]. In this context, it is interesting that birds which exhibit IOT when discriminating between shapes and colours[7-9] also completely lack IOT when visual spatial memories are involved in the task to be solved, for example, when food sources must be located on the basis of landmark information[21].

On the other hand, a monocular ant can read a learned compass direction from the pattern of polarized light in the sky irrespective of whether it uses the trained eye or the naive eye. In the latter case, this might be explained very simply. In bees, and probably also in ants, the ability to use polarized sky patterns as a compass is restricted to a small specialized part of the retina located at the uppermost dorsal margin of the insect's eye[22]. According to our current understanding of how this specialized area is used as a celestial compass[23,24], the compass information read from the sky by one eye is identical to that read by the other eye. It seems that one eye can substitute for the other when the areas of the two eyes involved convey identical messages to the nervous system. In these experiments, IOT has been inferred from unilateral stimulation by light[26], but as the contralateral eye was not occluded, one cannot dismiss the possibility that the response was due to stimulation of the rather large binocular field of view or to stray light artefacts.

Voltage-dependent potassium currents in cultured astrocytes

Stuart Bevan & Martin Raff

Zoology Department, University College London, Gower Street, London WC1E 6BT, UK

Astrocytes are a major cell type in the mammalian central nervous system (CNS), yet their functions remain uncertain. There are two principal classes of these glial cells—protoplasmic astrocytes, found mainly in grey matter, and fibrous astrocytes, which occur mainly in white matter[1]. Recently, these two types of astrocytes have been distinguished in cultures of developing CNS and have been shown to be biochemically distinct[2]. Because both types contain large numbers of glial filaments *in vitro* and hence appear 'fibrous', we will refer to them as type 1 (protoplasmic) and type 2 (fibrous) astrocytes[2]. Most type 2 astrocytes in culture share several properties with neurones[2]; for example, they have a process-bearing morphology and bind tetanus toxin and the monoclonal antibody A2B5 (ref. 3), both of which recognize specific gangliosides[3,4] and were initially considered to be neurone-specific markers in the CNS[3,5,6]. We have therefore investigated whether type 2 astrocytes also share electrophysiological properties with neurones. Using intracellular microelectrode and 'whole-cell' (patch-clamp) recording techniques, we have now found that both type 1 and type 2 astrocytes in culture have time- and voltage-dependent potassium ion conductances which, until recently, were considered to be confined largely to electrically excitable cells.

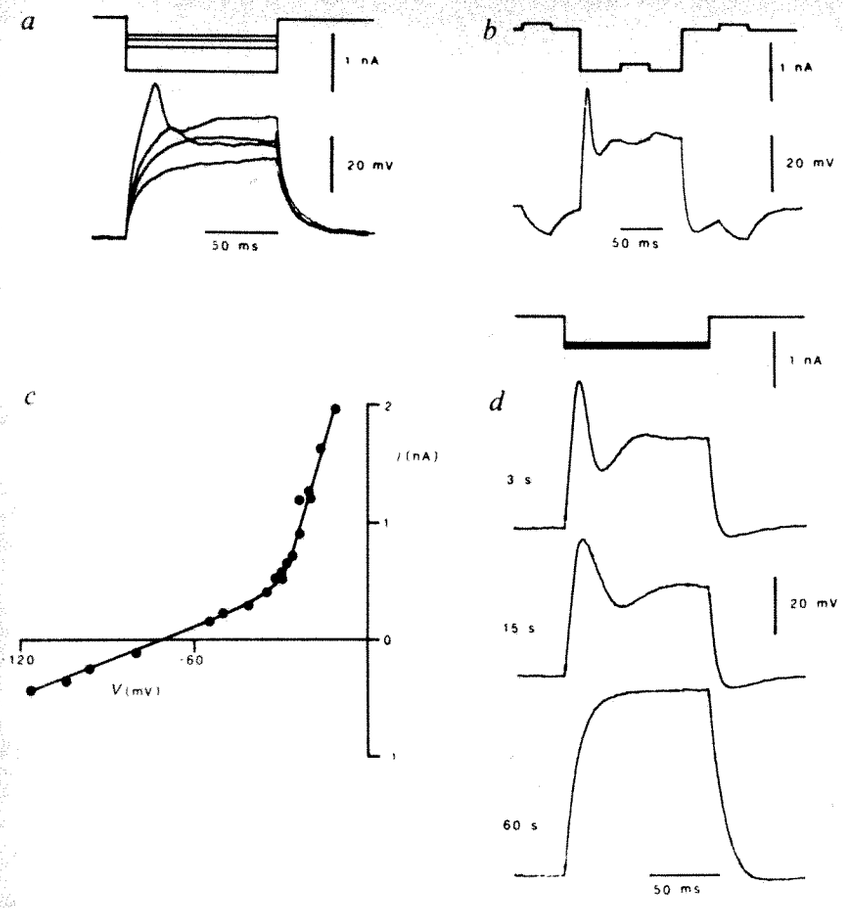

Fig. 1 *a*, Voltage response (lower trace) of a type 2 astrocyte to depolarizing current pulses of varying amplitude (upper trace). Resting potential, −78 mV. *b*, Hyperpolarizing current pulses delivered before, during and after a depolarizing pulse (upper trace) show that the membrane conductance is increased during the plateau phase of the voltage response (lower trace). Resting potential, −75 mV. *c*, Current-voltage (*I*-*V*) plot for depolarizing and hyperpolarizing current pulses shows an increase in membrane conductance for depolarizations to >−40 mV. The membrane potential was measured at the end of the current pulse, on the plateau phase of the voltage response. *d*, Membrane responses to depolarizing current pulses injected from a 2 M CsCl-filled intracellular microelectrode at the specified times after electrode impalement. Note the initial complex nature of the depolarizing response and its disappearance with time. The current pulse for the middle voltage trace is slightly smaller than for the other two traces. Resting potential, −80 mV. Except where noted, intracellular microelectrode studies were made on cells bathed in a recording solution of (mM): 145 NaCl, 5 KCl, 10 $CaCl_2$, 5 HEPES-NaOH *p*H 7.4. The use of a high calcium concentration improved the quality of electrode impalement and gave more negative and more stable membrane potentials. Microelectrodes of resistance 30–45 MΩ were filled with 3 M KCl except in *d*. Current pulses were delivered through the recording electrode which was connected to a bridge circuit. Temperature, 19–21 °C.

Cells from 7-day-old Sprague-Dawley rat optic nerves were dissociated and cultured on poly-L-lysine-coated plastic culture dishes in Dulbecco's modified Eagle's medium containing 10% fetal calf serum (FCS) as previously described[2,7]. We have previously shown that there are no neurofilament-containing neurones in such cultures[2] and that >90% of the process-bearing cells are type 2 astrocytes, as determined by labelling with A2B5 antibody and antibodies against glial fibrillary acidic protein (GFAP)[8]. The remaining process-bearing cells are oligodendrocytes, as determined by their labelling with antibody against galactocerebroside (GC)[8,9].

After 2–5 days in culture, cells with a typical type 2 astrocyte morphology[2] were examined electrophysiologically. Resting membrane potentials, measured with an intracellular microelectrode, were in the range −65 to −85 mV (mean ± s.d. = −79.6 ± 5.9 mV; $n = 29$). When the cells were polarized by injecting current pulses, a 'passive' membrane response was noted for small depolarizing or hyperpolarizing responses; however, with larger depolarizing pulses the response was more complex and a delayed reduction in the size of the depolarization was observed (Fig. 1*a*). This decline in amplitude to a plateau level was associated with an increase in membrane conductance, which was detected in two ways. First, when small hyperpolarizing current pulses were delivered before, during and after the depolarization (Fig. 1*b*), the evoked hyperpolarization was reduced during the plateau phase of the response. Second, when the relationship between the amplitudes of the injected current and the membrane potential near the end of the pulse was examined, a clear increase in membrane conductance was noted with depolarizations beyond −40 mV (Fig. 1*c*).

This voltage-dependent response was not affected by removal of external Na^+ (by replacement with *N*-methyl-D-glucamine), by addition of tetrodotoxin (TTX, 10 nM), by reducing the external Ca^{2+} level to 10^{-8} M with added EGTA or by addition of the Ca^{2+}-channel blocking agents La^{3+} (1 mM), Cd^{2+} (10 mM) and nifedipine (1 μM) to a nominally 'calcium-free' solution. In contrast, the response was attenuated by addition of the K^+-channel blocking drugs, tetraethylammonium (TEA, 10 mM) and 4-aminopyridine (4-AP, 5 mM). Furthermore, the voltage-activated increase in membrane conductance was greatly reduced when cells were impaled with microelectrodes containing Cs^+, which blocks K^+ channels in many cell types[10,11]. Figure 1*d* shows the response of a type 2 astrocyte to similar current pulses delivered 3, 15 and 60 s after penetration with a CsCl-filled microelectrode; a reduced voltage- and time-dependent response occurred as Cs diffused into the cell from the pipette. These findings suggest that the channels mediating the response to depolarization are similar to voltage-gated K^+ channels found in neurones and muscle cells.

To investigate this voltage-dependent response further, type 2 astrocytes were studied by the patch-clamp method with 'whole-cell' voltage-clamp recordings[12]. The measured resting potential, with 145 mM KCl in the patch pipette ($[K^+]_o = 5$ mM), was −80.1 ± 3.5 mV (mean ± s.d., $n = 21$), which is close to the value calculated from the Nernst equation for an exclusively K^+-permeable membrane. Figure 2*a* shows a family of voltage-clamp currents evoked by depolarizing voltage steps from a holding potential of −80 mV. After the initial capacity current, time- and voltage-dependent outward currents occurred with depolarizations to >−40 mV. This is shown graphically in Fig. 2*b*, where the current amplitude at the end of the depolarizing pulse is plotted against membrane potential. The voltage-dependent response was altered when Cs^+ (10 mM), TEA (10 mM) or 4-AP (2 mM) was included in the internal solution of the patch pipette; depolarizing steps now no longer evoked a persistent outward current. However, with Cs^+ present, an outward current was observed which peaked within a few milliseconds and then rapidly became inactivated, declining exponentially to a steady level with a time constant of ~30 ms (Fig. 2*c*). Unlike the persistent outward current, this transient current was abolished if the holding potential was set to levels >−40 mV. Because, in our experimental conditions, this current is outward at negative membrane potentials, it also must be carried largely by K^+ ions.

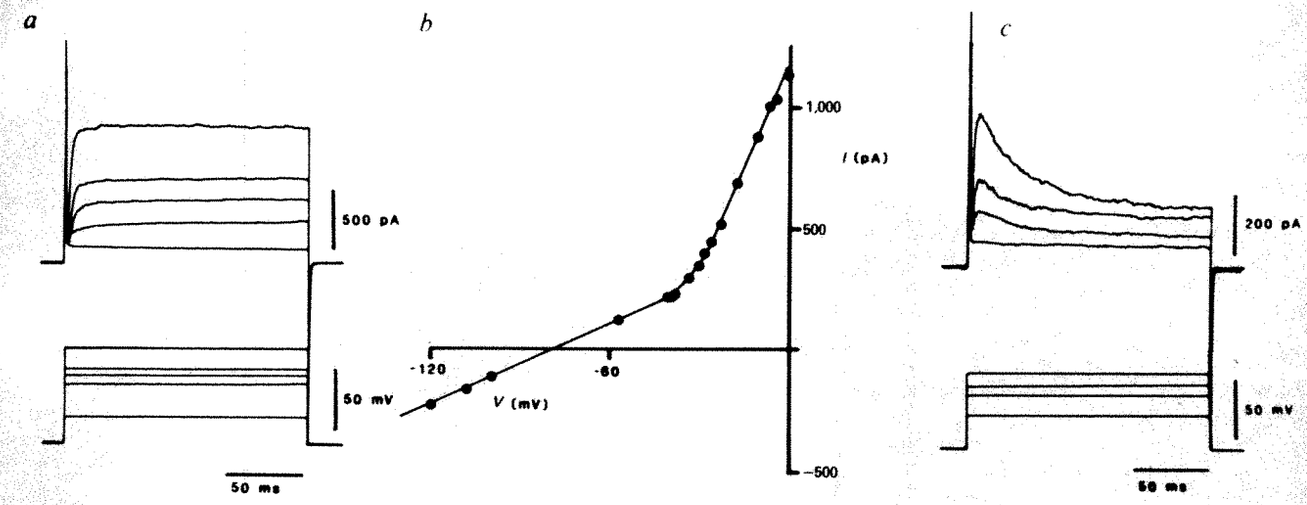

Fig. 2 Voltage clamp studies on type 2 astrocytes made with the whole cell (patch clamp) recording method. *a*, *c*, Outward currents (upper traces) evoked by depolarizing voltage command steps (lower traces) from a holding potential of −80 mV; time-dependent currents are evoked by depolarizations to > −40 mV. Cell resting potentials: *a*, −80 mV; *b*, −83 mV. In *c* the solution in the patch pipette was supplemented with 10 mM CsCl. *b*, *I*-*V* plot of 'steady-state' current for the cell shown in *a*. For these studies, cells were bathed in a recording solution containing 2 mM $CaCl_2$. Patch pipettes (3–8 MΩ resistance) were filled with (mM): 145 KCl, 5 NaCl, 1 EGTA, 5 HEPES-KOH *p*H 7.4. TEA (10 mM), 4-AP (2 mM) or CsCl (10 mM) was added to this solution as required. Gigaohm seals (>25 GΩ) were formed between the patch pipette and the membrane surface by gentle suction; increased suction then ruptured the underlying membrane to give whole-cell recordings. No series resistance or capacity compensations were made for the illustrated records. Temperature, 20–22 °C. The complex geometry of the cells means that although voltage control of the soma is good, the long processes will be poorly clamped. However, this does not affect the basic reported features of the evoked currents, as the kinetics and reversal potentials of the whole-cell currents and of the macroscopic currents in outside-out membrane patches are indistinguishable.

To determine whether type 1 astrocytes in culture have similar voltage-and time-dependent K^+ conductances, we examined cultures of type 1 astrocytes prepared from neonatal rat cortex by a modification of the McCarthy and de Vellis procedures[13] described elsewhere[2]. More than 95% of the cells in such cultures were $A2B5^-$, $GFAP^+$ type 1 astrocytes. Only cells that were not in contact with other cells were examined electrophysiologically, to avoid any problems introduced by electrical coupling between contiguous cells[14]. Type 1 astrocytes had similar resting membrane potentials to type 2 astrocytes and also showed a voltage- and time-dependent outward current on depolarization (Fig. 3*b*). Examination of the 'tail' currents seen immediately after stepping back from a depolarized level to various holding potentials (−60 to −100 mV) indicated a reversal potential of ~−85 mV, which is consistent with these voltage-activated channels being primarily K^+-permeable.

To determine whether cultured oligodendrocytes have similar K^+ conductances, we examined oligodendrocytes in optic nerve cultures prepared from 7-day-old rats; the cells were grown in a modified Bottenstein and Sato medium containing 0.5% or no FCS for 2–5 days as described previously[8]. In these cultures, more than 95% of process-bearing cells are GC^+, $GFAP^-$ oligodendrocytes[8]. Although such cells had resting membrane potentials similar to those of type 1 and type 2 astrocytes, no voltage-dependent conductances were activated when the cells were depolarized to levels up to +20 mV. Figure 3*a* shows the membrane response to depolarizing pulses and the current-voltage relationship for a typical oligodendrocyte. Similar results with cultured oligodendrocytes have been reported by Kettenmann *et al.*[15]. The electrophysiological differences between type 2 astrocytes and oligodendrocytes must appear rapidly during development, because it has been shown that both of these cells develop within 2 days *in vitro*[7] from a common progenitor cell present in 7-day-old optic nerve[8]: in the presence of 10% FCS, the bipotential progenitor cell differentiates into a type 2 astrocyte, while in serum-free medium it differentiates into an oligodendrocyte[8]. It is not clear whether the progenitor cell itself has the voltage-dependent conductances seen in type 2 astrocytes

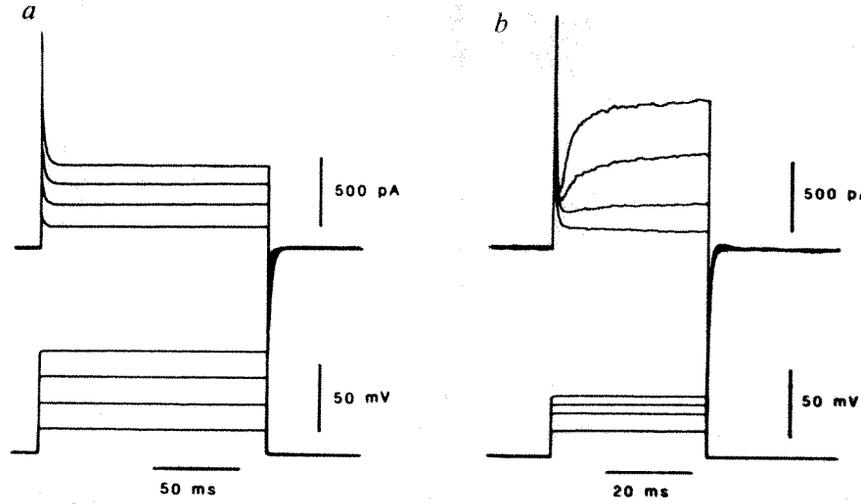

Fig. 3 Voltage clamp studies on an oligodendrocyte (*a*) and a type 1 astrocyte (*b*). Before electrophysiological examination, the flat type 1 astrocytes were usually rounded-up by a brief (~10 min) preincubation in a low-calcium-containing solution; this procedure eliminated most of the cell processes and thus improved the spatial control of membrane voltage. Whole-cell recordings show a voltage- and time-dependent K^+ current for type 1 astrocytes but not for oligodendrocytes. Holding potentials, −80 mV.

and loses them when it differentiates to become an oligodendrocyte, or whether the progenitor cell acquires these conductances on becoming a type 2 astrocyte. In either case, the changes in membrane conductance properties must occur within 2 days.

Thus, we have demonstrated voltage-activated K^+ conductances in type 1 and type 2 astrocytes in culture; these were not found in oligodendrocytes. Such conductances are activated when the cell is depolarized beyond −40 mV and seem to result from the opening of K^+ channels. The outward current normally observed in type 2 astrocytes shows little or no inactivation with time (over several seconds) and is blocked by TEA, 4-AP and Cs^+; this conductance resembles the delayed rectifier found in nerve and muscle cells. In the presence of internal Cs^+, a smaller, rapidly inactivating outward current is seen. The kinetics of this current may reflect a voltage-dependent block of the delayed rectifier-type channels by Cs^+ (see ref. 16) or the presence of a second type of K^+-permeable channel in the membrane. Our findings suggest that at least some of the neural tumour cell lines reported to contain voltage-dependent K^+ channels as well as glial cell antigens[17] arose from astrocytes or their precursor cells.

We have shown that astrocytes in culture display voltage-activated K^+ channels. This finding complements the recent reports of veratridine- and voltage-activated Na^+ channels[18,19] and voltage-dependent Ca^{2+} channels[20] in type 1 astrocytes. The biological significance of these conductances in astrocytes will remain uncertain until the functions of these cells are known.

Expression of T-cell antigen receptor genes during fetal development in the thymus

H. Ralph Snodgrass, Zlatko Dembić, Michael Steinmetz & Harald von Boehmer

Basel Institute for Immunology, Grenzacherstrasse 487, CH-4058 Basel, Switzerland

The T-cell antigen receptor is a heterodimeric molecule composed of α- and β-subunits of relative molecular mass 40,000–50,000 (refs 1–6). Recently, the genes encoding both the β-[7–9] and α-[10–12] chains have been cloned. By comparing amino-acid and nucleic-acid sequences, it is clear that these genes encode the α- and β-proteins of the T-cell receptor[13,14]. In addition, a third receptor-like gene, the γ-chain gene, has been identified[15], which has many structural and sequence characteristics in common with the α- and β-chain genes. The role of the γ-chain gene in T-cell development is unknown. We have reported recently that the β-chain genes are transcriptionally turned on in the thymus at about day 17 of fetal development[16]. Here we report that the α-chain also is transcriptionally activated during this time, but that the γ-chain gene is active in the thymus at day 14, reaches a peak steady-state level at day 15 and rapidly declines thereafter. If the γ-chain gene has a functional role, it would seem to be involved very early in T-cell development, before the mature T-cell receptor is expressed.

The mouse thymus is initially colonized by blood-borne precursors during days 11 and 12 of gestation[17]. Cell-surface molecules with the characteristics of the T-cell antigen receptor do not appear until day 17 (ref. 16) and functional cells do not appear in appreciable numbers until day 19 (refs 18, 19). Consistent with this, the α and β loci are transcriptionally active around day 17 of gestation (Fig. 1); this is evident not only in the absolute levels of messenger RNA, but also in the amounts of the larger transcripts (1.6, 1.3 and 1.5 kilobases (kb) for α, β and γ, respectively) relative to those of the smaller transcripts (1.3, 1.0 and 1.2 kb for α, β and γ, respectively). This is important because in the case of the β-chain gene, the larger transcript represents the full-length functional mRNA, whereas the smaller mRNA is an aberrant transcript representing only rearrangements of the diversity-joining-constant gene regions[20,21]. As reported previously[16,22], the levels of β-chain mRNA reach a peak in the adult thymus and drop substantially in peripheral T cells, in contrast to steady-state levels of α-chain mRNA, which reach a maximum by day 19 and remain high in peripheral T cells.

From the data presented in Fig. 1, it is impossible to compare the relative amounts of α, β and γ mRNA because of the different sizes of probes used and the different exposure times. A more quantitative estimate of the relative levels of expression is obtained from the number of clones of each of these genes present in a complementary DNA library. A library of 5×10^4 independent cDNA clones was prepared from day 17 fetal thymocytes, containing 50 (0.1%) β-chain clones and 5 (0.01%) clones each of the α- and γ-chains. (In a similar experiment, Chien *et al.*[10] found frequencies of 0.01% (α), 0.2% (β) and 0.002% (γ) in the adult thymus and 0.03% (α), 0.1% (β) and 0.002% (γ) in peripheral T cells.) These differences in expression between day 17, adult thymus and peripheral T cells are reflected in the hybridization intensities shown in Fig. 1. The inverse relationship in the expression of the α- and γ-chain genes is striking. The γ-chain gene is transcribed at high levels early in differentiation and then transcription declines rapidly at the time when the α-chain gene is becoming activated.

These data further support our previous conclusions[16] that the mature receptor seen on peripheral T cells is first expressed in the thymus at ~day 17 of gestation. The role of the γ-chain gene is unknown. Our data are consistent with a change in receptor repertoire during ontogeny, as suggested in some models[23,24]. One speculation, consistent with the expression of the α-, β- and γ-chain genes during ontogeny, is that the β- and γ-proteins form receptors that have specificity for major histocompatibility complex (MHC) antigens either alone or in combination with a ubiquitous cell-surface antigen; in other words, perhaps the β/γ combination is a MHC-restricted receptor specific for a nonpolymorphic cell-surface determinant. Thymocytes with the β/γ combination specific for self-MHC antigens are induced to differentiate. One of the differentiation steps would include the turning-off of the γ-chain gene and turning-on of the α-chain gene. The new α/β receptor would now (or perhaps after another round of selection) have specificity for a wide range of non-MHC antigens and for self-MHC. The binding site for self-MHC would be contributed by the β-chain, whereas the binding site for non-MHC would be formed by both the α- and β-chains. Although this, in effect, suggests the

presence of two binding sites, the overall functional specificity would depend on the specific α/β combination. Such a model is compatible with what is known about the structure of the β-chain variable region[25], as well as the extent of variability of the other two genes[10,11,15]. This would explain the lack of observed mixing of specificities in somatic cell hybrids (ref. 26 and W. Haas, personal communication). There is no direct evidence either for or against such a model. More information is needed concerning the expression of the γ-chain on the cell surface and the repertoire of the three genes before and after thymic selection.

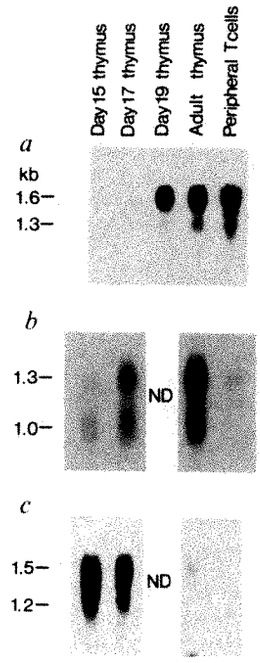

Fig. 1 Northern blot analysis of T cells at various stages of development. Total RNA (20 μg) was separated on 1.2% glyoxal gels[27], transferred to Gene Screen (NEN) and hybridized with an α-chain probe (*a*), β-chain probe (*b*), or γ-chain probe (*c*). *b*, From ref. 16; ND, not done.

Methods. B10.BR fetal thymocytes were obtained from timed matings where the day of vaginal plug detection was designated as day 0. RNA was isolated by the guanidinium isothiocyanate and CsCl gradient centrifugation procedures[28,29]. RNA blots were hybridized in 1 M NaCl, 50 mM Tris *p*H 7.5, 1% SDS, 0.2% polyvinylpyrrolidone, 0.2% bovine serum albumin, 0.2% Ficoll, 100 μg ml^{-1} denatured salmon sperm DNA, 10% dextran sulphate and 1.5×10^6 c.p.m. ml^{-1} oligo-labelled[30] probe (10^9 c.p.m. μg^{-1}) at 68 °C overnight. Filters were washed in 0.3 M NaCl, 60 mM Tris *p*H 8, 2 mM EDTA twice at 25 °C for 10 min and twice at 68 °C for 30 min, and twice in 10 mM NaCl, 6 mM Tris *p*H 8, 2 mM EDTA at 25 °C. Exposure was overnight with intensifying screens (Ilford Fast Tungstate). Sizes of RNA molecules were estimated from denatured phage DNA restriction fragments of known lengths run in parallel on the same gel. All probes are gel-purified inserts. The α-chain probe is the 300-base pair (bp) *Nco*I/*Ava*II fragment from the constant portion of the α-chain cDNA clone T1.2 (ref. 12). The β-probe is the 300-bp insert of the 4.4-kb cDNA clone from the constant portion of the β-chain gene starting ~50 bp downstream of the joining (*J*) gene segment (M. Kiefer and M.S., unpublished results). This clone was isolated together with the 4.1-kb β-chain cDNA clone, as described previously[16]. The γ-chain probe represents the 1.3-kb insert of the Tγ5 cDNA clone containing an almost full-length γ-chain cDNA as determined by comparison of this clone with published[15] γ-chain cDNA clones. The Tγ5 cDNA clone was isolated from an EL-4 cDNA library with a 33-residue oligonucleotide specific for the constant (C_γ) gene segment (M.S., W. Bannwarth and M. Kiefer, unpublished results). This cDNA clone has a 105-bp deletion starting at amino acid −4 and extending to amino acid 32 (numbered according to ref. 15; A. Traunecker, personal communication), presumably a result of aberrant splicing.

We thank Carina Olsson, Katrin Schubiger and Gholam Dastoornikoo for technical assistance; Wilhelm Bannwarth for synthesizing the oligonucleotide probes; Lynn Gisler for preparing the manuscript; and Werner Haas and Pawel Kisielow for helpful discussions. The Basel Institute for Immunology is supported by F. Hoffmann-La Roch and Co., Basel, Switzerland.

Note added in proof: Since the submission of this manuscript, Raulet and co-workers[31] have reported results consistent with the data presented here.

Interleukin-2 stimulates association of protein kinase C with plasma membrane

William L. Farrar* & Wayne B. Anderson†

Interleukin-2 (IL-2) is a regulatory peptide important for the growth and differentiation of antigen-specific T lymphocytes and large granular lymphocytes[1,2]. Interaction of IL-2 with its specific receptor results in the promotion of S-phase progression as well as, in certain circumstances, the production and release of γ-interferon (IFN-γ)[3–5]. Although the binding of IL-2 with high-affinity specific receptors has been well characterized[6,7], the intracellular mechanisms by which this ligand–receptor interaction promotes growth and differentiation are unknown. Here, we present evidence that IL-2/receptor interaction produces a rapid and transient redistribution of protein kinase C (PK-C) from the cytosol to the plasma membrane. Phorbol myristate acetate (PMA) also induces PK-C transposition in an analogous manner, except that PMA-induced PK-C transposition to the plasma membrane is apparently protracted. As phorbol esters have been shown to mimic IL-2 in the regulation of cellular proliferation as well as IFN-γ production[8–10], the activation of PK-C by either phorbol esters or IL-2/receptor interaction seems to have a crucial role in signal transduction elicited by these extracellular messengers.

Figure 1 shows the time course of IL-2-induced protein kinase C activity. IL-2-dependent murine CT6 cells grown in 5 units of IL-2 per 10^5 cells were washed in serum-free medium three times, 24 h before experimental stimulation. The cells were

washed twice more, resuspended to 1×10^7 cells ml^{-1}, and incubated at 37 °C for 2 h. Approximately 500 units of recombinant IL-2 were added per 10^7 cells and the PK-C-specific activity in the cytosol and plasma membrane were compared at the indicated time intervals. Within 3 min of IL-2 stimulation, an increase in PK-C-specific activity of over fourfold was observed in the plasma membranes of CT6 cells compared with unstimulated controls. Increases in membrane-associated PK-C activity of over 10-fold were observed by 10 min after IL-2 stimulation, followed by a rapid decline of plasma membrane PK-C activity at 20 min and a return to initial PK-C membrane-specific activity by 60 min. Concomitant with the rapid increases of PK-C membrane-associated activity, there was a precipitous decline in PK-C activity within the corresponding cytosol preparations obtained at the same time intervals. Although a decline in cytosolic PK-C activity was seen as early as 1 min after IL-2 stimulation, the lowest PK-C cytosolic activity was observed at 10 min, corresponding to peak plasma membrane-associated activity. Cytosolic PK-C activity progressively increased to basal levels by 60 min in the continuous presence of IL-2. In the same experiment, we compared the effects of PMA with those of IL-2. As reported previously[11], PMA (10 ng per 10^6 cells) stimulated a rapid (1 min) association of PK-C with particulate membranes. The PMA-stimulated membrane association of PK-C was approximately twofold greater than that stimulated by IL-2 and exhibited a more protracted dissociation from CT6 plasma membranes. CT6 cytosolic PK-C activity rapidly declined within 1 min of phorbol ester stimulation and was depressed to 50–115 pmol throughout the experiment. Similar data were obtained in a previous study in which murine thymoma EL4 cells were stimulated with phorbol esters[11]. The present results indicate that the decrease in cytosolic PK-C activity and consequent membrane association is not limited to phorbol ester-treated EL4 cells or parietal yolk sac (PYS-2) cells[11,12]. Indeed, IL-2, a growth-stimulating peptide, induced a substantial decrease in cytosolic PK-C activity with a concomitant increase in the plasma membrane-associated activity (Fig. 1). Attempts to dissociate PK-C from the membrane fraction of PMA- or IL-2-treated CT6 cells with high-salt (0.3 M NaCl)-Tris buffer or with buffer containing metal chelators (1 mM EDTA and EGTA) have been unsuccessful (data not shown), suggesting that PK-C has become a tightly associated integral membrane component.

To further investigate whether there is a direct correlation between IL-2-induced PK-C membrane association and IL-2-induced stimulation of proliferation of CT6 cells, we compared the dose-response curve for PK-C membrane association with that for IL-2-induced proliferation. Figure 2 shows the results of a typical experiment comparing the effects of recombinant IL-2 on PK-C plasma membrane association and CT6 proliferation; the titration curves have similar slopes. Concomitant with the increased membrane association of PK-C, there was a decrease in cytosol-specific activity, with half-maximal translocation of kinase activity in both membrane and cytosol occurring within an equivalent range of IL-2 activity (65–85 units). These dose-response kinetics further reinforce the notion that cytosolic PK-C became associated with the plasma membrane. In a related study, crude homogenates were preapared from control, IL-2- or PMA-stimulated CT6 cells and the total homogenate was extracted (cytosol plus membrane) with Nonidet P-40 (NP40). The resulting detergent-solubilized, DEAE-purified total PK-C activity from either control, IL-2- or PMA-stimulated CT6 cells agreed within ±15%, indicating that neither IL-2 nor PMA significantly altered total enzyme activity (data not shown). Also, the 50% effective dose (ED_{50}) of IL-2 for both PK-C membrane association and IL-2 bioactivity (measured by the proliferative response of CT6 cells) titrated within the same range of IL-2 concentration (80–145 units), suggesting a close correlation between the activation of PK-C membrane association and those events involved in IL-2-induced proliferation of CT6 cells.

Phospholipid enzymatic degradation, particularly phosphatidylinositol and phosphatidylcholine turnover stimulated by a wide variety of neurotransmitters, hormones, growth factors and toxins, appears to generate transmembrane control of cellular functions[13–17]. Phosphatidylinositol (PI) turnover, specifically, has been shown to activate a novel protein kinase (PK-C) by the generation of a transient metabolite of PI degradation, diacylglycerol[18,19]. The activation of PK-C seems to play a crucial part in the signal transduction elicited by extracellular messengers[13]. Although PK-C is normally found in a functionally inactive form in the cytosol of a variety of resting cell types, phorbol esters have been shown to stimulate a rapid protracted association of PK-C with plasma membrane, whereupon the lipid-rich environment plus Ca^{2+} serve as cofactors for the activation of enzymatic kinase activity[11,12]. The process of phorbol ester activation of PK-C activity is believed to be independent of phosphatidylinositol hydrolysis and diacylglycerol formation. Phorbol esters apparently displace the physiochemical association between diacylglycerol and PK-C and, as a result, activate PK-C in the absence of phosphoinositides[20,21]. Interleukin-2, however, probably acts through a phosphatidylinositol hydrolysis-dependent process, as indicated by

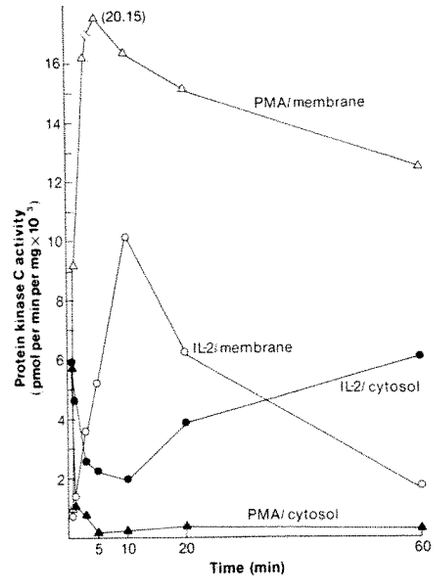

Fig. 1 Time course of association of PK-C with plasma membrane. IL-2-dependent CT6 cells were washed in serum-free RPMI-1640 medium and recultured in 1% fetal calf serum RPMI-1640 for 24 h. The cells were then washed twice and incubated at 37 °C in serum-free RPMI-1640 for 2 h before stimulation. Cells (1×10^7) were resuspended in 1 ml in Eppendorf tubes and stimulated with either 100 ng PMA or 500 U of recombinant human IL-2 (Biogen). The cells were maintained in a shaking water bath at 37 °C, removed at the indicated time intervals and washed three times in 1.0 ml serum-free RPMI-1640/1 mM sucrose. All liquids was absorbed from the cellular pellets and the cells were lysed in a 50-μl volume of distilled H_2O aspirated through a Hamilton syringe for 20 s. Immediately, the lysate was reconstituted with 1.0 ml ice-cold sample buffer (20 mM Tris *p*H 7.5, 0.33 M sucrose, 2 mM EDTA, 0.5 mM EGTA and 2 mM phenylmethylsulphonyl fluoride). Cytosol and particulate membrane fractions were prepared by centrifugation at 100,000 *g* for 60 min. Centrifuged membrane pellets were homogenized with a glass rod in 1% NP40 sample buffer, gently rotated for 30 min at 4 °C, and centrifuged at 12,000 r.p.m. for 15 min. Approximately 500 μl was passed through a 1-ml DE52 column equilibrated with sample buffer minus sucrose. Columns were washed with 15 ml sample buffer, 0.5 ml of 0.08 M NaCl, and an additional 1.5 ml of 0.08 M NaCl eluate was collected; all the PK-C activity was found in this fraction[11]. Aliquots (50 μl) were assayed for PK-C activity as described elsewhere[11,12] with 1 mM $CaCl_2$, 10 mM magnesium acetate, 100 μM [γ-^{32}P]ATP (60 c.p.m. $pmol^{-1}$), 50 μg HI histone, with or without 5 μg phosphatidylserine and 1 μg diolein. Data are expressed as PK-C-specific activity (pmol per min per mg) attributed to activity stimulated by phospholipid.

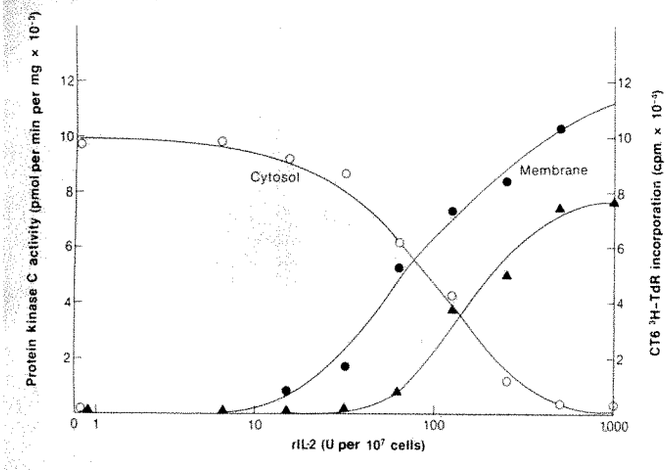

Fig. 2 Dose-response of IL-2-stimulated PK-C membrane association and cellular proliferation. CT6 cells were washed and prepared as described in Fig. 1 legend, then the indicated doses of recombinant IL-2 (rIL-2) were added and the cells were incubated for 10 min, followed by washing and lysis. Aliquots of the cell suspensions were taken and proliferation was measured in a standard IL-2 bioassay[5]. Proliferation data are expressed as the mean c.p.m. of triplicate cultures seeded with 1×10^4 cells per microculture (▲); PK-C activity in membrane (●) and cytosol (○) was determined as described in Fig. 1 legend and elsewhere[11].

the transient nature of the PK-C membrane association (Fig. 1). Preliminary experiments using isolated plasma membranes from IL-2-dependent cell lines have demonstrated that the principle metabolites formed on *in vitro* IL-2 stimulation of the isolated membranes were the PI metabolites phosphatidylinositol 4′-monophosphate and phosphatidylinositol 4′, 5′-bisphosphate (data not shown). However, diacylglycerol, a neutral lipid, could not be recolved by the single-dimension TLC analysis employed. Even though diacylglycerol is generated by PI hydrolysis, it is rapidly converted to phosphatidic acid and arachidonic acid, which may therefore explain the membrane association/dissociation kinetics observed with IL-2. Phorbol esters, on the other hand, are not readily degraded enzymatically and therefore substitute for diacylglycerol for a more protracted period[22].

Recent studies have shown that an initial event induced by growth stimulators is enhanced phosphorylation of specific membrane proteins[23,24]. The products of several different viral transforming genes have also been demonstrated to be protein kinases[25,26] and association with the plasma membrane seems to be required for *in vivo* tumour formation[27-29]. In addition, the Rous sarcoma virus transforming gene product, $pp60^{v\text{-}src}$, and the UR2 transforming protein of avian sarcoma virus have been shown to have lipid kinase activity which phosphorylates PI and diacylglycerol, suggesting a mechanism for transformation involving the initiation of PI turnover which, in turn, can activate several protein kinase activities including PK-C[30,31]. Our studies suggest that IL-2 activates a protein phosphorylation system, PK-C, which is also associated with the biological activity of tumour promoters and certain oncogenes[13-15,30,31]. The data are consistent with the notion that oncogenes may mimic or interact at different discrete events in phosphorylating systems that are normally stimulated by ligand-receptor interactions, and thereby initiate a cascading series of events associated with cellular proliferation. The finding that IL-2 initiates PK-C activation defines an event necessary for the growth of lymphoid cells, and allows the development of a model for the mechanism of action of as yet undefined oncogenic elements that may be involved in leukaemogenesis.

We thank Mr Harold Stull for technical assistance and Drs J. J. Oppenheim, R. B. Herberman and F. Ruscetti for helpful suggestions in the preparation of this manuscript.

Altered cytosol/membrane enzyme redistribution on interleukin-3 activation of protein kinase C

William L. Farrar*, Thomas P. Thomas† & Wayne B. Anderson†

* Laboratory of Molecular Immunoregulation, National Cancer Institute-Frederick Cancer Research Facility, Frederick, Maryland 21701, USA
† Laboratory of Tumor Immunology and Biology, National Cancer Institute, Bethesda, Maryland 20205, USA

Interleukin-3 (IL-3) is a member of a family of growth and differentiation peptides, collectively referred to as colony-stimulating factors, which regulate haematopoiesis[1-3]. IL-3 has been highly purified from medium conditioned by WEHI-3B cells, and recently the molecular cloning of complementary DNA for murine IL-3 has been reported[4,5]. IL-3 seems to stimulate a wide range of colony-forming cells derived from murine bone marrow and has consequently been studied under a variety of names, including burst-promoting activity[6], mast cell growth factor[7], P-cell stimulating factor[8] and multi-colony-stimulating factor[3,9]. Here we present evidence that IL-3-receptor interaction stimulates the rapid and transient redistribution of protein kinase C (PK-C) from cytosol to plasma membrane in FDC-P1 cells. Phorbol myristate acetate (PMA) is shown to have a similar effect in these IL-3-dependent FDC-P1 cells. Our data suggest that IL-3 and phorbol esters share a common feature of transmembrane signalling crucial for growth and differentiation.

FDC-P1 cells were established originally as a cell line dependent for its sustained growth and viability on conditioned media derived from WEHI-3 cells[10]. Ihle and colleagues established that IL-3 is the principal factor within WEHI-3 conditioned media which is responsible for the growth promotion of FDC-P1 cells[11]. In the present studies, FDC-P1 cells were washed free of support conditioned medium, rested for 2 h in serum-free media and stimulated with 100 ng PMA per 10^7 cells. At various times after PMA addition, the cells were washed, lysed and the

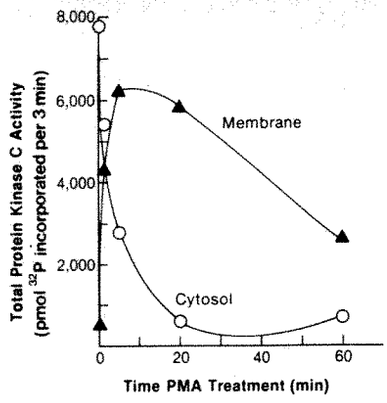

Fig. 1 Time course of the effect of PMA treatment of FDC-P1 cells on cytosolic (○) and particulate (▲) protein kinase C. FDC-P1 cells were grown in the presence of 10% FCS-RPMI 1640 and 20% WEHI-3 conditioned medium as described elsewhere[11]. The cells were washed extensively, reconstituted with serum-free RPMI-1640 at a density of 1×10^7 per experimental point, then incubated for 2 h in a 37 °C water bath in Eppendorff tubes before stimulation with 100 ng PMA. After addition of PMA, at the indicated time intervals, cells were collected and washed rapidly three times with RPMI 1640, 1 M sucrose and pelleted in a microfuge. The cellular pellet was lysed within 20 s in 50 μl of double-distilled water by passage through a narrow-gauge needle and immediately reconstituted with 1.0 ml ice-cold buffer A (20 mM Tris-HCl *p*H 7.5, 0.5 mM EGTA, 2 mM EDTA, 2 mM phenylmethylsulphonyl fluoride). Lysates were centrifuged at 100,000*g* and cytosol and membrane particulate fractions obtained. Particulate membrane fractions were solubilized with buffer A containing 1% NP40 detergent and both cytosolic and solubilized membrane fractions were fractionated by DEAE-cellulose chromatography as described in detail elsewhere[14]. Fractions eluting with 0.08 M NaCl contained all the detectable PK-C activity[14]. Aliquots (50 μl) of DEAE-purified material were assayed for cytosolic and particulate Ca^{2+}, phospholipid-dependent PK-C activity in the presence of 10 mM Mg acetate, 0.75 mM $CaCl_2$, 100 μM [γ-^{32}P]ATP (60 c.p.m. pmol^{-1}) and 25 μg of histone H1, with or without 24 μg phosphatidylserine and 1.6 μg diolein[14]. Protein kinase activity was determined by subtracting the amount of ^{32}P incorporation into histone noted in the absence of added phospholipids, from the amount of ^{32}P incorporation noted in the presence of phospholipids. Total protein kinase C activity is expressed as the pmol ^{32}P incorporated per 3 min per total volume of each cytosolic and membrane preparation.

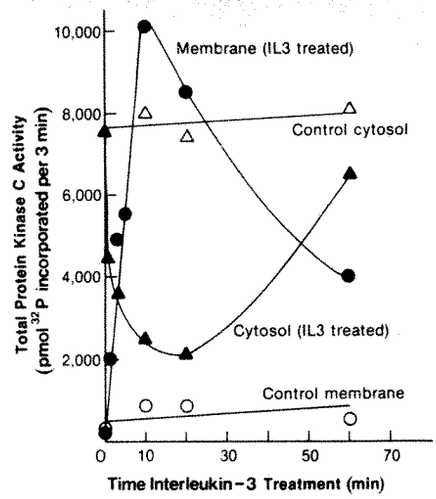

Fig. 2 Time course of the effect of IL-3 treatment of FDC-P1 cells on cytosolic and particulate protein kinase C. Washed FDC-P1 cells were prepared as for Fig. 1. Following preincubation in serum-free medium, 10^7 cells were stimulated with 100 U of homogeneous IL-3 prepared from WEHI-3 conditioned media[4]. Other cells were incubated in the absence of IL-3 to serve as the control cell population. At the indicated time intervals, the cells were washed, lysed and centrifuged at 100,000*g* to prepared cytosolic (△, ▲) and membrane (○, ●) fractions from control (closed symbols) and IL-3-treated (open symbols) cells, as described in Fig. 1 legend. Cytosol and NP40 detergent-solubilized particulate preparations were applied to and eluted from DE52-cellulose columns and protein kinase C activity was determined in the presence and absence of phospholipids as described for Fig. 1.

Ca^{2+}, phospholipid-dependent PK-C activity which was measured in the cytosol and detergent-solubilized membrane fractions was isolated.

Figure 1 shows a time-kinetic comparison of the total PK-C activity in cytosol and membrane fractions of FDC-P1 cells treated with PMA. Within 1-2 min of PMA addition, cytosolic PK-C activity had begun to fall rapidly; it had fallen 10-fold within 20 min of incubation in the presence of PMA and remained depressed for the remainder of the time course. Concomitant with the decrease in cytosolic PK-C activity, there was an equally rapid (1-2 min) increase in membrane-associated PK-C resulting in a 10-fold increase in total enzyme activity by 10 min post-treatment. Examination of the total cellular enzyme activity (membrane + cytosol) revealed no changes in total PK-C activity with PMA stimulation (data not shown). Rather, the data suggested that PMA mediates a redistribution of PK-C activity from cytosol to membrane. These findings are consistent with previous studies demonstrating similar PK-C translocations from cytosol to plasma membrane in phorbol ester-treated murine thymoma EL4 cells, interleukin-2 (IL-2)-dependent CT6 cells and parietal yolk sac cells (PYS)[12-15].

FDC-P1 cells were washed free of support WEHI-3 conditioned medium, incubated for 2 h at 37 °C in serum-free RPMI 1640, stimulated with 100 U of purified IL-3 (U = reciprocal dilution at half-maximal proliferation)[4] and the time course of cytosol- and membrane-associated PK-C activity was evaluated (Fig. 2). Unstimulated FDC-P1 cells contained ~7,500 U PK-C cytosolic activity (1 U = 1 pmol ^{32}P incorporated in 3 min). Treatment with IL-3 resulted in a precipitous decrease in cytosolic PK-C activity within 1-3 min (from 7,500 to 3,500 U), with a greater than threefold decrease within 20 min post-IL-3 treatment. This IL-3-stimulated decline of cytosolic PK-C activity was transient, however, and was followed by a return to near control levels by 60 min post-stimulation. Control cytosolic PK-C activity (no IL-3 added) did not change significantly (±15%) during FDC-P1 cell incubation, and total control membrane-associated detergent-solubilized PK-C activity was considerably lower (100-200 U) than control PK-C cytosolic activity (7,500 U).

Concomitant with the rapid loss of cytosol PK-C activity was an equally marked increase in membrane-associated activity, resulting in a >10-fold increase in membrane-associated activity within 10-20 min post-IL-3 treatment. Control (no IL-3 added) membrane PK-C activity did not change significantly during cell incubation. The return (increase) of cytosolic PK-C activity 20-60 min after IL-3 addition was associated with a corresponding decrease of membrane-associated activity. Total cellular (membrane + cytosol) PK-C activity did not change significantly during the exposure to IL-3, suggesting that the reciprocal kinetics of cytosolic and membrane-associated PK-C activity results from IL-3-mediated PK-C enzyme translocation between soluble and particulate fractions.

Figure 3 depicts the dose-response curve noted for IL-3-stimulated DNA synthesis relative to the membrane-association kinetics of PK-C activity in FDC-P1 cells. Incubation of FDC-P1 cells for 15 min with increasing concentrations of IL-3 (to 500 U) caused a progressive, IL-3 dose-dependent decrease in cytosolic PK-C activity, while particulate PK-C activity increased. The increase in detergent-solubilized PK-C activity in response to IL-3 was proportional to the dosage of IL-3 used to treat the FDC-P1 cells. The proliferative dose-response of FDC-P1 cells to IL-3 paralleled the membrane-association kinetics of PK-C,

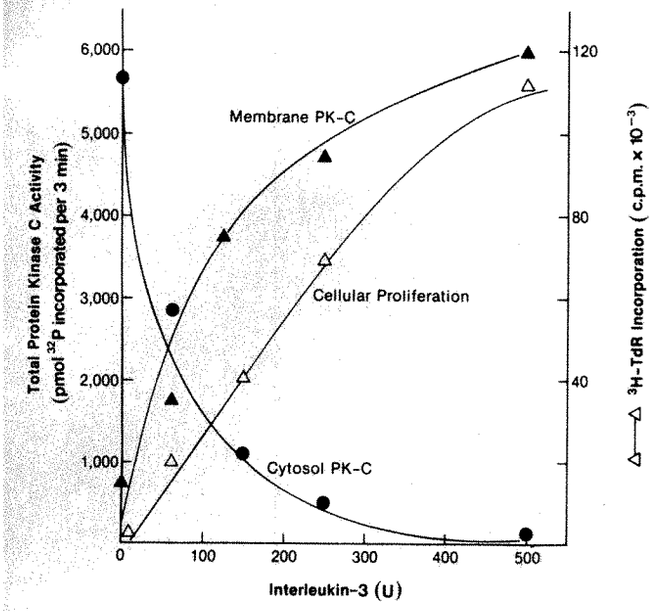

Fig. 3 Effect of treatment of FDC-P1 cells with increasing concentrations of IL-3 on the subcellular redistribution of protein kinase C activity and on DNA synthesis. To determine the dose response of IL-3 on PK-C activity, FDC-P1 cells were incubated with the indicated dosages of purified IL-3 for 15 min. The cells were washed and cytosol (●) and particulate (▲) membrane fractions prepared as for Fig. 1. Cytosolic and detergent-solubilized membrane preparations were separated by DEAE-cellulose chromatography to determine the total PK-C activity as described in Fig. 1 legend. Cellular proliferation (△) was determined by measuring the incorporation of ^{3}H-thymidine (TdR) as described elsewhere[11]. Cellular proliferation is expressed as the mean c.p.m. of triplicate cultures of 3×10^4 cells per culture.

and the IL-3 ED_{50} for both the increase in membrane-associated PK-C activity and FDC-P1 DNA synthesis was within the same dose range (200–250 U). These results suggest a quantitative relationship between PK-C membrane association and the proliferative response of FDC-P1 cells to IL-3.

The data presented here demonstrate that a haematopoietic growth factor, IL-3, stimulates a rapid and transient increase in the redistribution of PK-C activity from cytosol to the membrane (Fig. 2). IL-3 probably acts through a phosphoinositide hydrolysis-dependent mechanism involving the generation of diacylglycerol, as indicated by the transient nature of the membrane association. Phorbol esters, however, are not readily degraded enzymatically and may, therefore, become associated with the enzyme in place of the apparent physiological regulator for a protracted period, which would allow a more prolonged association of PK-C with the membrane and override other regulatory capabilities of the cell (such as the rapid metabolism of diacylglycerol) (Fig. 1)[16,17].

In related studies, IL-2, a lymphocytotropic growth factor, also stimulates transient PK-C subcellular redistribution[12]. The similarity of the IL-2-induced PK-C activation process and IL-3 suggests that growth or progression peptides share common features of transmembrane biochemical signals involved in growth promotion. Interestingly the viral transforming gene products *src* and *ros* have recently been demonstrated to possess lipid kinase activity[18,19]. This would presumably result both in the activation (and membrane association) of PK-C in response to increased diacylglycerol levels and to increased intracellular Ca^{2+} levels in response to the polyphosphoinositides[16,20]. Taken together, the data are consistent with the hypothesis that oncogenic elements mimic certain ligand–receptor interactions, thereby initiating a series of transmembrane phosphorylation events which are normally triggered by extracellular growth peptides[19–21].

Selective inhibition of the anchorage-independent growth of *myc*-transfected fibroblasts by retinoic acid

Anita B. Roberts, Nanette S. Roche & Michael B. Sporn

Laboratory of Chemoprevention, National Cancer Institute, Bethesda, Maryland 20205, USA

Fischer rat 3T3 (FR3T3) fibroblasts transfected with a cellular *myc* gene[1] can be induced to grow and form colonies in soft agar by treatment either with epidermal growth factor (EGF) alone or with the combination of platelet-derived growth factor (PDGF) and type-β transforming growth factor (TGF-β)[2]. We now show that induction of anchorage-independent growth by each of these sets of growth factors involves different cellular pathways which can be distinguished by their sensitivity to retinoic acid. Colony formation induced by the combined action of PDGF and TGF-β is 100-fold more sensitive to inhibition by retinoic acid than is colony formation induced by treatment of the *myc*-transfected cells with EGF. Moreover, retinoic acid (10^{-8} M) is inhibitory for colony growth whenever TGF-β is present, regardless of whether the effects of TGF-β are stimulatory, as occurs in the presence of PDGF, or inhibitory, as found in the presence of EGF[2].

The cellular mechanisms of induction of anchorage-independent growth by peptide growth factors such as PDGF[3–5], TGF-β[6–8] and the TGF-α family[9–11] (which includes EGF) are poorly understood. These three distinct families of growth factors[12–15] share the ability to induce phenotypic transformation of non-neoplastic fibroblasts, as measured by growth in soft agar[16–18]. The increased secretion of TGF-α[19,20], PDGF[21] and TGF-β[22] which accompanies virus transformation of cells provides further evidence for the role of these peptides in expression of the transformed phenotype. It has recently become apparent that the product of the *myc* gene, acting in the nucleus, is involved in the pathway by which a mitogenic stimulus is generated by a growth factor acting on its receptor[23–28]. For example, treatment of quiescent fibroblasts with PDGF, which induces a state competent for replication[29], results in transient expression of the *myc* gene[30]. Consistent with this observation, BALB/c 3T3 cells transfected with *myc* partially lose their requirement for PDGF[31]. Thus, whereas control cells require both PDGF and EGF for growth in monolayer culture in plasma[29], *myc*-transfected cells can grow in plasma in the presence of EGF alone[31].

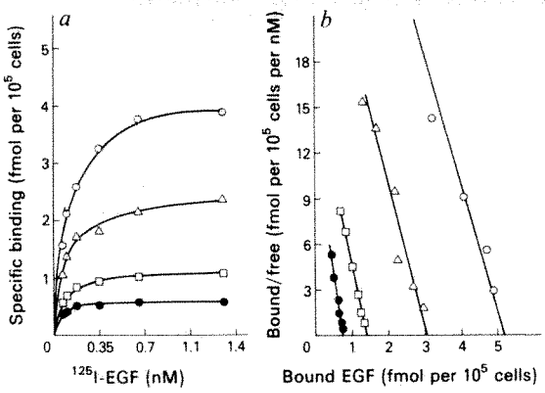

Fig. 1 Retinoic acid increases the number of cell-surface EGF receptors on Myc-1 cells. *a*, Binding of ^{125}I-labelled EGF (150 μCi μg^{-1}) to Myc-1 cells grown either in the absence of added retinoic acid (●) or in the presence of 10^{-8} M (□), 10^{-7} M (△) or 10^{-6} M (○) retinoic acid. *b*, Scatchard plot of the data in *a*.

Methods. The Myc-1 cell line was derived from FR3T3 fibroblasts by co-transfection of a neomycin-selectable marker gene and a construct in which exons 2 and 3 of a cellular *myc* gene derived from a mouse plasmacytoma were put under control of the SV40 early promoter (plasmid pSVc-myc-1)[1]. Cells were seeded in 1 ml of Dulbecco's modified Eagle's medium containing 5% calf serum at a density of 1×10^4 cells per 16-mm multiwell dish. Retinoic acid (in 20 μl of a 2% solution of dimethyl sulphoxide in medium) was added 4 h after seeding and the incubation was continued for 60 h before the binding assay[37]. Binding of ^{125}I-labelled EGF was measured at room temperature in the absence of retinoic acid. Nonspecific binding, measured in the presence of unlabelled EGF at a concentration of 1 μg ml^{-1}, was subtracted from all values. Results are the average of triplicate determinations.

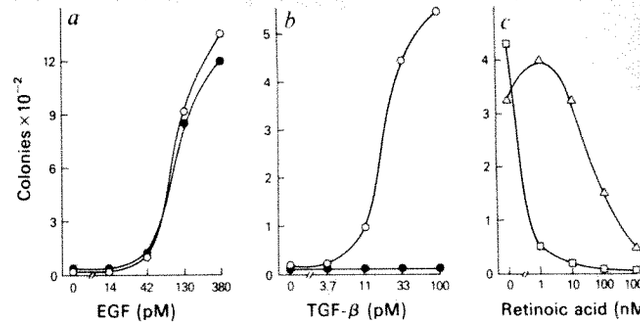

Fig. 2 Selective inhibition by retinoic acid of the anchorage-independent growth of Myc-1 fibroblasts in the presence of PDGF and TGF-β. *a*, Colony growth assayed in the presence of EGF alone. *b*, Colony growth assayed in the presence of 150 pM PDGF and the concentration of TGF-β indicated. *c*, Colony growth assayed in the presence of 42 pM EGF alone (△) or the combination of 150 pM PDGF and 100 pM TGF-β (□) and varying concentrations of retinoic acid. Myc-1 cells were assayed for the formation of colonies of >62 μm diameter after 7 days' incubation in soft agar in Dulbecco's modified Eagle's medium, 10% calf serum as described previously[37]. Purified murine EGF, human PDGF or human platelet TGF-β[7] were added at the time of the assay[2] in the presence (●) or absence (○) of 10^{-8} M retinoic acid.

Transfected NIH 3T3 or Rat-2 cells expressing an activated *myc* gene are tumorigenic and have an increased, though low (1%), cloning efficiency in soft agar compared with control cells[32]. We have shown that FR3T3 cells transfected with exons 2 and 3 of a cellular *myc* gene under control of the simian virus 40 (SV40) early promoter[1] (Myc-1 cells) do not grow in soft agar, but can be induced to form colonies by the addition of growth factors[2]; control cells transfected with the neomycin marker alone cannot form colonies. Myc-1 cells require only EGF to form colonies[2], and PDGF has little additional effect on cell growth in the presence of optimal concentrations of EGF. In contrast, PDGF is essential for anchorage-independent growth of Myc-1 cells in the presence of TGF-β[2]. This suggests that one function of PDGF may be to induce expression of other genes[33] in addition to *myc* which are required in the signalling pathways of TGF-β.

To probe for possible mechanistic differences in the action of EGF and TGF-β on anchorage-independent growth of Myc-1 cells, we investigated the effects of retinoic acid on the growth factor-dependent colony formation of the cells. Retinoic acid is known to inhibit colony growth of certain tumour cells and *in vitro* transformation of fibroblasts (reviewed in ref. 34). Previous studies suggest that retinoic acid[35-37] and TGF-β[38] may share common mechanistic elements, since they both increase the number of EGF receptors of normal rat kidney (NRK) cells. In the present study, retinoic acid treatment (60 h) of Myc-1 cells similarly resulted in a dose-dependent increase in the number of cellular EGF receptors, 10^{-8} M, 10^{-7} M and 10^{-6} M retinoic acid producing a respective two-, four- and seven-fold increase in the number of EGF receptors (Fig. 1*a*,*b*), with no apparent effect on receptor affinity. However, in contrast to the stimulatory effects of this increased number of EGF receptors on soft agar growth of NRK cells[35-37], treatment of Myc-1 cells with retinoic acid (10^{-8} M) had little effect on the dose-dependent induction of anchorage-independent growth by EGF (Fig. 2*a*). Concentrations of retinoic acid >10^{-8} M inhibited EGF-induced colony formation; 10^{-7} and 10^{-6} M retinoic acid produced 50 and 85% inhibition, respectively (Fig. 2*c*). Retinoic acid treatment of control FR3T3 cells transfected with the neomycin marker resulted in an increase in EGF binding similar to that observed in Myc-1 cells; however, the increased binding did not alter the inability of these cells to grow in soft agar either in the presence or absence of added growth factors (not shown). This suggests that these effects of retinoic acid on increasing the number of EGF receptors of transfected FR3T3 cell lines are unrelated to its effects on EGF-dependent colony growth of the cells in soft agar.

Remarkably, colony formation stimulated by treatment of Myc-1 cells with PDGF and TGF-β is ~100-fold more sensitive to inhibition by retinoic acid than is the EGF-dependent colony formation (Fig. 2*c*). Thus retinoic acid (10^{-8} M) is a potent inhibitor of colony formation stimulated by treatment of the cells with PDGF and TGF-β (Fig. 2*b*). The inhibition could not be overcome by increasing the TGF-β concentration as high as 100 pM (Fig. 2*b*), and concentrations of retinoic acid as low as 10^{-9} M still inhibited colony formation by >90% (Fig. 2*c*). Retinoic acid had little or no effect on either the number or affinity of cellular TGF-β receptors (not shown).

To study separately the effects of retinoic acid on the action of either PDGF or TGF-β on Myc-1 cells, we examined the effects of 10^{-8} M retinoic acid on colony growth in the presence of EGF with additions of either PDGF or TGF-β (Fig. 3*a*, *b*). PDGF slightly potentiated the action of suboptimal levels of EGF on colony formation (Fig. 3*a*), whereas we had shown previously that TGF-β partially inhibits the effect of EGF on growth in soft agar (ref. 2 and Fig. 3*b*). Retinoic acid had either no effect or slightly stimulated the colony growth induced by PDGF in the presence of 42 pM EGF (Fig. 3*a*). However, retinoic acid synergized with TGF-β to abolish the colony formation induced by treatment of Myc-1 cells with 420 pM EGF (Fig. 3*b*). Thus, in the absence of retinoic acid, TGF-β (10–100 pM) inhibits EGF-dependent colony formation to a maximum of 60% (ref. 2 and Fig 3*b*), but when Myc-1 cells are treated with 10^{-8} M retinoic acid, which by itself has no effect on EGF-dependent colony formation (Fig. 2*a*), concentrations of TGF-β >~10 pM result in nearly total inhibition of the colony-forming response (Fig. 3*b*).

The discriminating action of low concentrations of retinoic acid on growth factor-dependent colony formation by Myc-1 cells was observed only in conditions of anchorage-independent growth. Growth of the cells in monolayer culture was consistently inhibited by TGF-β and either unaffected or stimulated by retinoic acid (10^{-7} M), regardless of the particular combination of growth factors added (Table 1). Thus, the selective action of retinoic acid cannot be related mechanistically to the growth of cells *per se*, but rather, specifically to its effects on processes

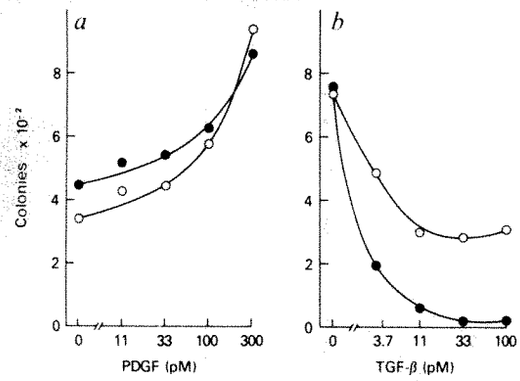

Fig. 3 Inhibition by retinoic acid is dependent on the presence of TGF-β. *a*, Myc-1 cells assayed in the presence of 42 pM EGF and increasing concentrations of PDGF. *b*, Colony growth assayed in the presence of 420 pM EGF and increasing concentrations of TGF-β. Myc-1 cells were assayed for colony formation in soft agar in the presence (●) or absence (○) of 10^{-8} M retinoic acid as described in Fig. 2 legend.

Table 1 Effects of retinoic acid on growth of Myc-1 cells in monolayer culture

Additions	No. of cells per dish ($\times 10^{-4}$) −Retinoic acid	+Retinoic acid (10^{-7} M)
None	6.6	6.5
EGF (800 pM)	10	13
PDGF (200 pM)	15	19
TGF-β (4 pM)	1.2	1.6
EGF+TGF-β	2.2	4.8
PDGF+TGF-β	7.3	13

Cells were seeded into 16-mm multiwell dishes at a density of 1×10^4 cells per well in 1 ml of Dulbecco's modified Eagle's medium containing 2% calf serum. Retinoic acid, in 20 µl 2% dimethyl sulphoxide in medium, and growth factors, in 10–20 µl 4 mM HCl, were added 16 h after seeding. Cell counts were determined in triplicate in a Coulter counter 4 days after seeding.

correlated with transformation of cells, namely anchorage independence[39].

Although PDGF, EGF and TGF-α have a consistent stimulatory effect on the growth of cells in both anchorage-dependent and independent conditions, the actions of TGF-β on cells are known to be bifunctional[2,40]. For example, we have shown here that TGF-β stimulates the anchorage-independent growth of Myc-1 cells in the presence of PDGF (Fig. 2*b*), but inhibits both the anchorage-dependent growth of the cells in the presence of PDGF or EGF (Table 1) and colony formation in the presence of EGF (Fig. 3*b*). Recently, TGF-β has been shown to be similar, or possibly identical, to a growth inhibitor isolated from African green monkey kidney cells[41]. The results presented here—that retinoic acid can selectively modulate the effects of TGF-β on *myc*-transfected cells—emphasize the distinctive mode of action of this growth factor and suggest that mitogenic effects of TGF-β on growth of cells in soft agar use different intracellular signalling pathways from those involved in transduction of mitogenic stimuli from either PDGF or EGF and their receptors. Most significantly, these results suggest that retinoic acid can be used to discriminate between different mechanisms of cellular transformation and between different pathways of growth factor action on cells.

We thank Drs David F. Stern and Robert Weinberg for providing the Myc-1 cell line, Dr Richard Assoian for helpful discussions, Dr Gary Grotendorst for providing PDGF, and Mr Joseph M. Smith and Dr Lalage M. Wakefield for assistance with the binding assays.

Association of phosphatidylinositol kinase activity with polyoma middle-T competent for transformation

Malcolm Whitman*, David R. Kaplan†, Brian Schaffhausen‡, Lewis Cantley* & Thomas M. Roberts†

Polyoma middle-T antigen is required for viral transformation of cultured cells and for tumorigenesis in animals. Like many other transforming gene products, middle-T is bound to the membrane and has an associated tyrosine kinase activity *in vitro*[1,2]. This activity seems to result from the interaction of middle-T with pp60$^{c\text{-}src}$, the cellular homologue of the transforming gene product of the Rous sarcoma virus, pp60$^{v\text{-}src}$ (refs 3–5). Both pp60$^{v\text{-}src}$ (ref. 6) and another retrovirus transforming gene product, pp68$^{v\text{-}ros}$ (ref. 7) were shown recently to have an associated phosphatidylinositol (PI) kinase activity *in vitro* and to increase PI turnover *in vivo*. These results suggest that viral transformation may be directly connected to a complex network of second messengers generated from PI turnover[8–18]. Here, we assayed for PI kinase activity in immunoprecipitates made with middle-T- or pp60$^{c\text{-}src}$-specific antisera of cells infected with polyoma virus. A PI kinase activity was detected in those immunoprecipitates which contained middle-T. Studies of mutants of middle-T defective in transformation indicate a close correlation between PI kinase activity and transformation.

Immunoprecipitates of polyoma middle-T from infected 3T3 cells catalyse phosphorylation of PI. Figure 1*a* shows the relative PI phosphorylating ability of immunoprecipitates obtained on treatment of mock-infected or polyoma-infected cells with polyoma-specific serum or preimmune serum. Immunoprecipitates made from polyoma-infected 3T3 cells with anti-polyoma serum (Fig. 1*a*, lane 4) produced 20-fold more phosphatidylinositol diphosphate (DPI) after a 20-min incubation than did immunoprecipitates made from mock-infected cells (lane 3). No increase in PI phosphorylation above background levels was seen when immunoprecipitates were made with preimmune serum (Fig. 1*a*, lanes 1, 2). Quantitation of the PI phosphorylation in 10 separate experiments gave 10–50-fold enhancement for middle-T immunoprecipitates over controls. Similar results were observed when polyoma-infected 3T6 cells, 293 cells infected with an adenovirus expressing the middle-T gene, and a polyoma middle-T transformed cell line (py14-2)[19] were compared with respective parent line or mock-infected controls (data not presented).

If the observed PI kinase activity is linked to the transformation activity of middle-T, virus mutations reducing transforming activity should reduce or eliminate the observed PI kinase activity of infected cell immunoprecipitates. Polyoma middle-T mutants defective in transformation fall into two categories: mutations that abolish transformation totally, like py1387T and NG59, and mutations that reduce but do not eliminate transforming activity, such as py1178T. py1387T contains a nonsense mutation which eliminates the last 37 amino acids at the C-terminus of middle-T, rendering it completely defective for transformation, membrane association and tyrosine kinase activity. Small-T is unaltered and large-T contains a single amino-acid substitution but is unaffected in its function[20]. Figure 1*b* shows the effect of this mutation on viral stimulation of immunoprecipitated PI kinase activity. Immunoprecipitates from cells infected with py1387T (Fig. 1*b*, lane 2) showed no increase in PI kinase activity over mock-infected control (lane *a*). Parallel infections and immunoprecipitations from ^{35}S-methionine-labelled cells indicated that py1387T-infected cells contain similar levels of large-T, middle-T and small-T to those seen in wild-type polyoma-infected cells (not shown). As judged by ^{3}H-thymidine uptake, py1387T and wild-type polyoma infection caused similar stimulation of DNA synthesis (data not shown). These results suggest that the PI kinase activity associated with polyoma immunoprecipitates may be linked to the transforming function of the virus and is not a consequence of cell stimulation by viral infection.

Experiments with the transformation-defective mutant NG59 indicate that the PI kinase activity associated with wild-type middle-T immunoprecipitates is not a consequence of membrane contaminants nonspecifically co-precipitated with membrane-bound middle-T. Like py1387T, NG59 is totally transformation defective, but unlike py1387T, the middle-T protein of NG59 associates with the membrane[21]. The mutation is a replacement of an aspartic acid residue at position 179 by isoleucine-asparagine. No PI kinase activity above background was detected using immunoprecipitates from cells infected with this virus (Table 1), even though ^{35}S-methionine labelling indicated that normal levels of mutant middle-T were present in the immunoprecipitates (not shown). Therefore, the PI kinase activity associated with middle-T is not merely a consequence of middle-T membrane association.

Unlike middle-T antigens produced by NG59 and py1387T mutants, which are totally inactive in transformation and in the standard middle-T tyrosine kinase assay *in vitro*, the middle-T product of the py1178T mutant virus (in which a Phe is substituted for Tyr 315) retains some associated tyrosine kinase activity and is partially defective in transformation[22,23]. If PI kinase activity plays an important part in transformation, then immunoprecipitates of middle-T prepared from cells infected with this virus should be less active in PI phosphorylation than wild-type immunoprecipitates; this was observed (Fig. 2*a*). Although py1178T immunoprecipitates contained some PI

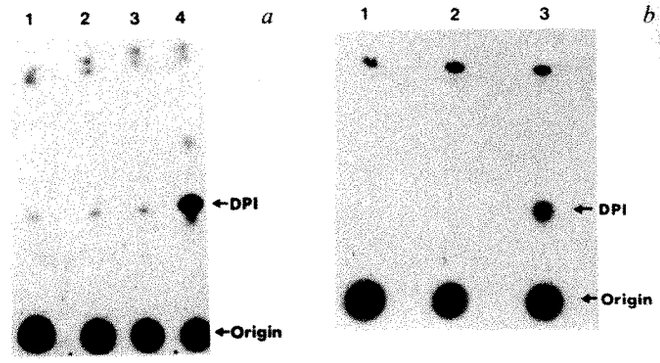

Fig. 1 Phosphorylation of phosphatidylinositol by polyoma immunoprecipitates. *a*, Autoradiograph of a TLC separation of the reaction products from PI kinase assays performed on immunoprecipitates. Lane 1, mock-infected NIH 3T3 cells precipitated with preimmune serum; lane 2, wild-type polyoma-infected cells precipitated with preimmune serum; lane 3, mock-infected cells precipitated with anti-polyoma serum; lane 4, wild-type polyoma-infected cells precipitated with anti-polyoma serum. *b*, Relative PI kinase activity of immunoprecipitates from transformation-defective versus wild-type viral infections. Immunoprecipitates using anti-polyoma serum were made and phosphorylation assays carried out as described below. Lane 1, immunoprecipitate from mock-infected cells; lane 2, immunoprecipitate made from cells infected with the transformation-defective mutant 1387; lane 3, immunoprecipitate from wild-type-infected cells. The position of migration of DPI is indicated. Spots present in all lanes near the top of the TLC are ATP contaminants which vary with the ATP shipment used, and do not depend on addition of either protein or phospholipid to the reaction mix. An additional spot appearing in *a*, lane 4, co-migrates with phosphatidic acid and seems to be due to the presence of a small amount of diacylglycerol in the added phosphatidylinositol.

Methods. NIH 3T3 cells, 24 h post-infection, were washed with cold phosphate-buffered saline, rinsed with 137 mM NaCl, 20 mM Tris *p*H 8, 1 mM $MgCl_2$, 1 mM $CaCl_2$ (buffer A), and lysed in buffer A containing 10% glycerol, 1% NP40, and 1 mM phenylmethylsulphonyl fluoride at 4 °C for 20 min. Insoluble material was removed by centrifugation at 4 °C for 10 min at 10,000*g*. The supernatants were incubated with 2 μl of rabbit anti-T serum (D. C. Pallas, M. E. Mahoney, D.R.K. and T.M.R., unpublished) or preimmune serum for 15 min at 25 °C. Sepharose Cl4B-protein A (Sigma) was added, and incubation continued for an additional 15 min. The immunoprecipitates were collected and washed once with cold phosphate-buffered saline, twice with 0.5 M LiCl, 0.1 M Tris *p*H 7.4, and finally with 10 mM Tris, 100 mM NaCl, 1 mM EDTA. Immunoprecipitates were then assayed for phosphatidylinositol phosphorylation activity: 1 mg ml^{-1} PI (Avanti) was dispersed by sonication for 15 min in 5 mM HEPES; the dispersed PI was preincubated at 4 °C with the immunoprecipitate for 20 min at a final concentration of 0.2 mg PI ml^{-1}. After preincubation, the phosphorylation reaction was started by addition of 20 μCi [γ-^{32}P]ATP and $MgCl_2$ to final concentrations of 50 μM ATP and 5 mM $MgCl_2$ in a volume of 50 μl. The reaction mixture was incubated for 20 min at 25 °C and terminated by addition of 100 μl of 1 M HCl. (Less than 10% of the ATP was consumed during the incubation as judged by chromatography on polyethyleneimine-impregnated cellulose in 2 M formate *p*H 3.5.) Phospholipids were then immediately extracted with 200 μl of $CHCl_3$/MeOH (1:1). The organic phase was washed once with 80 μl of MeOH/HCl (1:1) and spotted onto a silica gel 60 TLC plate (Merck) pretreated with 1% potassium oxalate. Phosphorylated products were separated by TLC in a $CHCl_3$/MeOH/4 M NH_4OH (9:7:2) developing solvent for 1 h and visualized by autoradiography. Unlabelled phospholipid standards were included and were visualized by exposure to iodine vapour. Identity of products was also confirmed by two-dimensional chromatography with cold standards; after chromatography in the first dimension in the system described above, plates were developed in the second dimension in $CHCl_3$/MeOH/CH_3COOH/H_2O (50:39:1:10) (not shown).

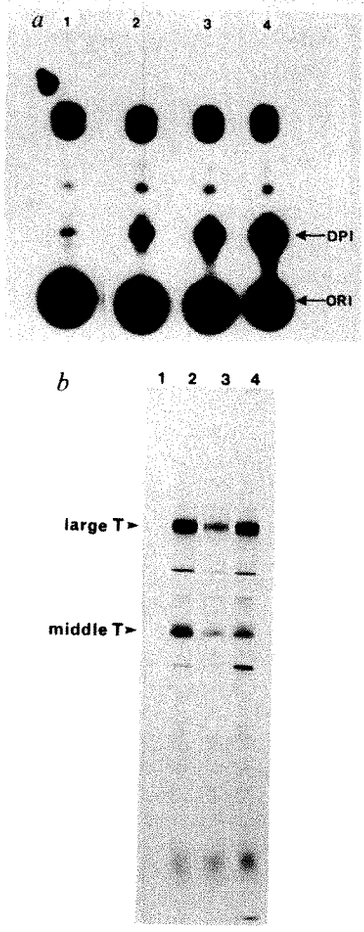

Fig. 2 Comparison of PI kinase activity and middle-T protein in immunoprecipitates from cells infected with wild-type and py1178T mutant of polyoma. NIH 3T3 cells were infected and immunoprecipitations and kinase reactions were performed as in Fig. 1 legend. The cells were labelled with 100 μCi ml^{-1} ^{35}S-methionine for 3 h before the immunoprecipitation. *a*, Autoradiogram for the PI kinase assay. Lane 1, mock-infected cells precipitated with anti-T serum; lane 2, py1178T-infected cells precipitated with anti-T serum; lane 3, cells infected with wild-type virus at 1/10th the py1178T virus multiplicity of infection; lane 4, cells infected with wild-type virus at the same multiplicity of infection as py1178T. *b*, Autoradiograph of ^{35}S-methionine-labelled proteins in the immunoprecipitates separated by SDS-polyacrylamide gel electrophoresis (10% acrylamide, procedure of Laemmli[33]). The order of lanes is the same as in *a*.

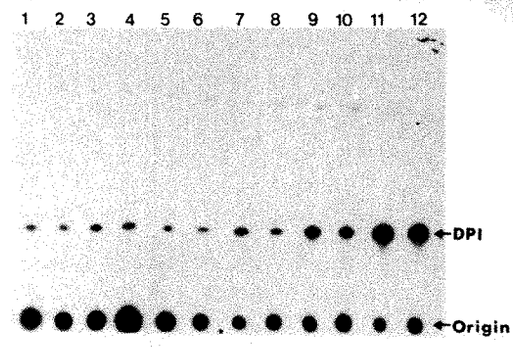

Fig. 3 PI kinase activity of immunoprecipitates made with anti-pp60$^{c\text{-}src}$ monoclonal antibody. Viral infections and immunoprecipitations were performed as described in Fig. 1 legend, except that supernatants were incubated with 3 μl of the anti-pp60$^{c\text{-}src}$ monoclonal antibody, GD11 (ref. 34), or an equal volume of rabbit preimmune serum for 30 min at 4 °C. PI kinase assays and product separations were performed as in Fig. 1. Lanes 1–6 are immunoprecipitates with control serum and lanes 7–12 are immunoprecipitates with GD11. Lanes 1, 2, 7 and 8 are from uninfected 3T3 cells; lanes 3, 4, 9 and 10 are from 3T3 cells infected with 1 plaque-forming unit per cell of wild-type polyoma virus; lanes 5, 6, 11 and 12 are from 3T3 cells infected with 10 plaque-forming units per cell of wild-type polyoma virus.

Table 1 Relative transformation abilities and PI kinase activities associated with middle-T mutants

Polyoma mutant	PI kinase activity	Transformation competence (ref.)	Association with pp60$^{c\text{-}src}$ (ref.)
RA (wild type)	100	++(29)	+(3, 4, 24)
Mock infected	7	—	—
py1387T	8	−(20)	+−/−(31)
NG59	10	−(25)	−(32)
dl45	165	++(30)	+(24, 31)
py1178T	23	+/−(22, 23)	+(31)

3T3 cells were either mock infected or infected with different polyoma mutants. Immunoprecipitations and kinase assays were carried out as described in Fig. 1 legend. For quantitation of PI kinase activity, the radioactive spot corresponding to DPI was cut out, and the silica gel was scraped into a scintillation vial and counted by liquid scintillation spectrometry. PI kinase activities are expressed as % of wild-type activity in immunoprecipitates where comparable amounts of the mutant middle-T protein to wild-type middle-T protein were present as judged by ^{35}S-methionine label. The values presented are the average of at least three separate experiments, except for d145, where the results of a single experiment are presented. References for the ability of the mutants to cause transformation and to associate with pp60$^{c\text{-}src}$ are given in parentheses.

kinase activity above background, this activity was reduced 5–10-fold relative to wild-type immunoprecipitates when infected cells were making comparable levels of middle-T, measured by incorporation of ^{35}S-methionine (Fig. 2*b*).

Cellular src (pp60$^{c\text{-}src}$) is associated with polyoma middle-T in immunoprecipitates from infected cells, suggesting that tyrosine phosphorylation of middle-T is catalysed by pp60$^{c\text{-}src}$ (ref. 3). Immunoprecipitates of pp60$^{c\text{-}src}$ were prepared from normal or polyoma-infected NIH 3T3 cells using the anti-pp60$^{c\text{-}src}$ monoclonal antibody GD11 (ref. 34). The immunoprecipitates from polyoma-infected cells (Fig. 3, lanes 11, 12) contained a PI kinase activity ~10-fold above controls (Fig. 3, lanes 5, 6). However, immunoprecipitates of pp60$^{c\text{-}src}$ from uninfected cells (Fig. 3, lanes 7, 8) or cells infected with py1387T (not shown) showed no detectable increase in PI kinase activity above controls. In five separate experiments, the pp60$^{c\text{-}src}$ immunoprecipitates from polyoma-infected cells showed a 5–20-fold stimulation in PI kinase activity compared with uninfected controls. There was no significant difference in the amounts of pp60$^{c\text{-}src}$ in immunoprecipitates from polyoma-infected cells and uninfected cells, in agreement with results of Bolen *et al.*[24]. Thus, middle-T increases the PI kinase activity of pp60$^{c\text{-}src}$ immunoprecipitates without increasing the amount of pp60$^{c\text{-}src}$.

Anti-T immunoprecipitates from cells infected with wild-type polyoma virus have at least 20-fold higher PI kinase activity than those from uninfected cells. This activity is correlated with the transforming ability of the virus. Non-transforming mutants NG59 (ref. 25) and py1387T (ref. 20) do not cause such an increase. As py1387T encodes normal large-T and small-T antigens, middle-T must be responsible for the associated PI kinase activity. py1178T has an intermediate phenotype. Its ability to transform F111 cells is severely impaired[23], but DNA containing the mutant sequence transforms Rat 1 cells normally[22]. Its PI kinase activity, like its transforming ability, is intermediate between those of wild-type and NG59 or py1387T. Like the pp60$^{v\text{-}src}$, some DPI kinase activity and diacylglycerol kinase activity is also associated with the middle-T immunoprecipitates, but these activities are at least fivefold lower than the PI kinase activity when compared at identical substrate and protein concentration (data not presented).

Parallel results were observed when the PI kinase experiments were carried out using anti-pp60$^{c\text{-}src}$ instead of anti-T serum. Background PI kinase activity made it difficult to decide whether pp60$^{c\text{-}src}$ from uninfected cells has PI kinase activity. Although the simplest model suggests that pp60$^{c\text{-}src}$ has a PI kinase activity which is activated by association with middle-T, the possibility that middle-T or an uncharacterized cellular protein associated with middle-T catalyses the PI phosphorylation cannot be excluded. Bolen *et al.*[24] have shown recently that pp60$^{c\text{-}src}$ immunoprecipitates have enhanced tyrosine kinase activity towards casein. Like pp60$^{v\text{-}src}$ (ref. 6) and pp68$^{v\text{-}ros}$ (ref. 7), the middle-T/pp60$^{c\text{-}src}$ complex may have broad specificity towards protein and lipid substrates. In our hands, the rate of phosphorylation of PI and the model substrate enolase are comparable, giving no clue to the relative importance of the two phosphorylation reactions.

The products of the phosphorylation reactions, phosphatidylinositol diphosphate and triphosphate, have themselves been implicated in the regulation of several membrane-bound enzymes, including the Ca^{2+}-ATPase[10,11] and a nuclear membrane RNA-dependent ATPase implicated in RNA transport[12,26,27]. Because polyphosphoinositides are the preferred substrates for phospholipase C[28], the increased PI kinase activity could raise cellular levels of the breakdown products diacylgycerol and inositol 1,4,5-trisphosphate; the latter compound regulates Ca^{2+} release from internal stores[8] and the former activates protein kinase C[14]. Increased levels of these potential second messengers could provide the pleiotropic response expected for transformation. Characterization of the effects of the middle-T antigen on *in vivo* PI metabolism will be required to confirm and define the physiological significance of this activity.

A group of membrane-associated guanine nucleotide binding proteins (G-proteins) are essential for transducing signals generated at cell-surface receptors into changes in cellular function and metabolism[1]. These proteins are a complex of three subunits designated α, β and γ. The α-subunit is responsible for binding guanine nucleotides and seems to be characteristic of each protein. Transducin, a member of this protein family, mediates visual transduction by coupling the signal of photolysed rhodopsin with activation of a cyclic GMP phosphodiesterase[2]. We have now cloned and sequenced the complementary DNA encoding the α-subunit of bovine retinal transducin and from this we have deduced the complete amino-acid sequence. The transducin α-subunit shares several homologous amino-acid sequences with *ras* gene products. The homologous segments correspond mostly to the regions thought to be involved in the guanine nucleotide binding and GTPase activity of *ras* proteins and to the ADP-ribosylation sites of the transducin α-subunit.

A library of cDNA clones was prepared using poly(A)$^+$ RNA from bovine retina as template and the plasmid expression vector pUC8 (refs 3, 4). Screening of the cDNA library[4] with monoclonal antibodies to the purified α-subunit of porcine retinal transducin yielded two immunologically positive clones from $\sim 8 \times 10^4$ transformants. One of these clones, pTα108, was found by nucleotide sequence analysis[5] to contain coding sequences for all six partial amino-acid sequences determined for the transducin α-subunit in the same reading frame (see below). To clone a longer cDNA sequence, we constructed another cDNA library derived from poly(A)$^+$ RNA from bovine retina, using the plasmid vector developed by Okayama and Berg[6]. Screening of this library[7] with a probe derived from the 5′-terminal region of the cDNA insert of clone pTα108 yielded 61 hybridization-positive clones from $\sim 6 \times 10^5$ transformants. From 36 randomly selected clones, we chose clone pTα13 for further study. It contained the whole cDNA sequence carried by clone pTα108 apart from the 3′-terminal 50-nucleotide sequence. The additional sequence in clone pTα108 seems to have resulted from a possible error during the construction of the cDNA expression library or DNA replication because the sequence was not present in any of the three other clones tested derived from the Okayama-Berg library.

Figure 1 shows the 2,446-nucleotide sequence (excluding the poly(dA) tract) of the cDNA encoding the α-subunit of bovine transducin, determined using clones pTα13 and pTα108. The reading frame corresponding to the six partial amino-acid sequences (amino acids 43-47, 83-96, 103-112, 139-157, 177-188 and 301-309) determined by peptide analysis (Fig. 3) was used to deduce the primary structure of the transducin α-subunit (Fig. 1). The translation initiation site was assigned to the methionine codon at nucleotides 1-3 because this is the first in-frame ATG triplet that occurs downstream of the nonsense codon TAG (nucleotide residues −81 to −79) and because the

Fig. 1 Nucleotide sequence of the cDNA for the bovine transducin α-subunit. Nucleotide residues are numbered in the 5′ to 3′ direction, beginning with the first residue of the ATG triplet encoding the initiating methionine, and the nucleotides on the 5′ side of residue 1 are indicated by negative numbers; the number of the nucleotide residue at the right-hand end of each line is given. The deduced amino-acid sequence of the transducin α-subunit is shown above the nucleotide sequence, and amino-acid residues are numbered beginning with the initiating methionine. Nucleotide residue 2,309 in the cDNA insert of clone pTα13 is followed by a poly(dA) tract, which is connected with the vector DNA sequence[6,35]. The AATAAA sequence[36] is found 15 nucleotides upstream from the polyadenylation site. Nucleotides 840 (T), 1,137 (G) and 1,336 (G) have been taken from pTα13 (carrying nucleotides −137 to 2,309), whereas the corresponding residues of pTα108 (carrying nucleotides −30 to 1,453) are C, A and A, respectively; the difference in residue 840 results in no amino-acid substitution.

described previously[39]. Using 34 μg of poly(A)$^+$ RNA, 805 ng of cDNA was obtained. The screening was carried out by incubation with a mixture of two monoclonal antibodies to the porcine transducin α-subunit (IgG2b isotype), then with ^{125}I-protein A (NEN); the monoclonal antibodies were prepared by the hybridoma technique[40]. Clone pTα108 was thus isolated. For the isolation of clone pTα13, a cDNA library was constructed by the method of Okayama and Berg[6], using 7.8 μg of poly(A)$^+$ RNA and 4.2 μg of the vector-primer DNA . The procedures of transformation and screening were as described previously[39]; the *Ava*II(−4)/*Ava*II(565) fragment from pTα108, labelled by nick-translation[41] with [α-^{32}P]dCTP, was used as hybridization probe.

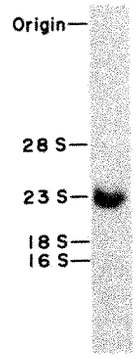

Fig. 2 Autoradiogram of blot hybridization analysis of bovine retinal RNA with a cDNA probe. Poly(A)$^+$ RNA (20 μg) was analysed by the procedure of Thomas[9]. The hybridization probe used was the *Eco*RI/*Sal*I-excised cDNA insert of clone pTα108, labelled by nick-translation[41] with [α-^{32}P]dCTP. The size markers used were bovine and *Escherichia coli* ribosomal RNA[45]. A hybridization-positive band of the same size was observed when the *Ava*II(−4)/*Ava*II(565) fragment derived from pTα13 was used as probe.

second ATG triplet encodes amino acid 49, which is preceded by one of the peptide sequences determined. A translation termination codon (TGA) occurs in-frame after the 350th codon specifying phenylalanine. Thus, we conclude that the bovine transducin α-subunit is composed of 350 amino-acid residues (including the initiating methionine) and has a calculated relative molecular mass of 39,964, which agrees with the reported value[2,8]. Blot hybridization analysis[9] of bovine retinal poly(A)$^+$ RNA with cDNA probes showed a hybridization-positive RNA species of ~2,900 nucleotides (Fig. 2).

The *ras* gene products, like the α-subunits of transducin and related proteins, are membrane-associated proteins that bind guanine nucleotides and have GTPase activity[10–13]. Comparison of the amino-acid sequences of the transducin α-subunit and the *ras* protein family reveals several homologous regions (Fig. 4*a*–*f*). Interestingly, regions *a*, *b* and *d* of *ras* p21 proteins correspond to the regions considered to be involved in guanine nucleotide binding. Region *a* of p21 corresponds to the sequence surrounding Gly 12; this sequence exhibits homology with the nucleotide binding region of the β-subunit of ATP synthase[14] as well as of several dinucleotide binding enzymes[15]. Region *b* of some p21 proteins contains a threonine at position 59 which is autophosphorylated by GTP (refs 11, 16). Furthermore, such proteins show a lower GTP binding affinity than do proteins with alanine at position 59 (ref. 13). Region *d* constitutes part of the homologous segment found in G-proteins[17] which has been suggested to lie adjacent to the nucleotide binding site in elongation factor-Tu[18]. Thus, regions *a*, *b* and *d* of the transducin α-subunit may also contribute to guanine nucleotide binding. Furthermore, mutations causing amino-acid substitutions at positions 12, 13, 59, 61 or 63 of p21 are known to enhance the transforming potential of *ras* genes[19–28] and p21-associated GTPase activity is selectively impaired by an amino-acid substitution at position 12 (ref. 13). Thus, region *a* of the transducin α-subunit, like that of *ras* proteins, may be involved in GTPase activity. Region *c* of the transducin α-subunit contains the tetrapeptide sequence Ser-Arg-Val-Lys, which has been identified as the site that is ADP-ribosylated by cholera toxin[29]. Region *f* represents the carboxy-terminal tetrapeptide sequence of both the transducin α-subunit and the *ras* proteins (except for the YP2 product) and in the transducin α-subunit, constitutes part of the peptide carrying the site that is ADP-ribosylated by islet-activating protein[30]. It has been proposed that the conserved cysteine in this region is involved in the post-translational events leading to the biologically active membrane-associated form of

p21 (ref. 31). Thus, the regions conserved between the transducin α-subunit and the *ras* proteins seem to correspond to the functional regions of the two groups of G-proteins.

Analysis of the amino-acid sequence of the transducin α-subunit reveals two highly hydrophobic regions with predicted secondary structure[32,33] which corresponds to continuous stretches of uncharged amino acids, including many nonpolar residues (residues 65–81 and 213–226). These regions may be involved in hydrophobic interaction with the other transducin subunits or with photolysed rhodopsin or the phosphodiesterase. Alternatively, they may contribute to the association of the protein with the plasma membrane.

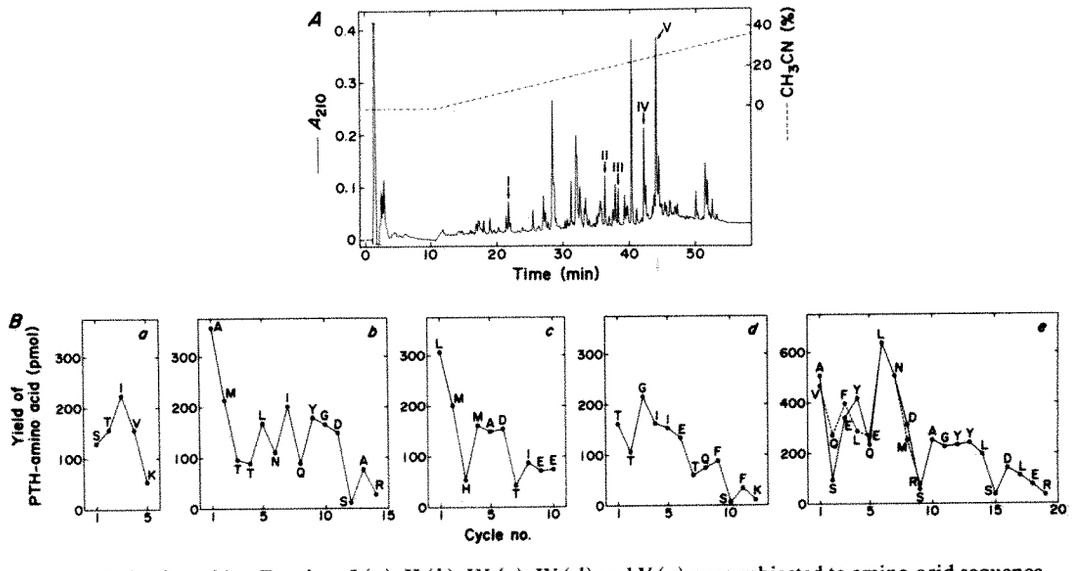

Fig. 3 Partial amino-acid sequence analysis of the α-subunit of bovine transducin. ***A***, Reverse-phase HPLC of tryptic peptides. The tryptic digest was loaded directly onto a Chemcosorb 3μ C_{18}-H column (8 × 75 mm; Chemco) equilibrated with 0.1% trifluoroacetic acid, and a linear gradient of 0–60% acetonitrile was applied over 80 min at a flow rate of 2 ml min^{-1}; a Hitachi 635 HPLC system with a solvent programmer was used. The eluate absorbance at 210 nm was recorded with a Hitachi 41 ultraviolet monitor. Five fractions (I–V) corresponding to absorbance peaks were collected. ***B***, Sequence analysis of peptides. Fractions I (*a*), II (*b*), III (*c*), IV (*d*) and V (*e*) were subjected to amino-acid sequence analysis with a gas-phase sequencer (model 470A, Applied Biosystems). Phenylthiohydantoin (PTH)-amino acids were analysed by HPLC at 50 °C using an Ultrasphere ODS column (4.6 × 250 mm; Altex) with a three-solvent gradient (acetonitrile, water and 40 mM sodium acetate buffer, *p*H 5.6) at a flow rate of 1 ml min^{-1}. The yield of PTH-amino acids at each cycle of Edman degradation is shown; the one-letter amino-acid notation is used. Fraction V was a mixture of two peptides, whose sequences were assigned as indicated, assuming that leucine and asparagine are shared by the two peptides at the sixth and seventh amino-acid positions, respectively.

Methods. Transducin was partially purified from rod outer segments, prepared from frozen bovine retinas, according to the procedure of Baehr *et al.*[8]. Approximately 20 mg of the partially purified transducin derived from about 1,000 retinas was subjected to electrophoresis on SDS-polyacrylamide gels[43] to purify each subunit; electroelution[44] from the gels yielded 620 μg, 780 μg and 300 μg of the α-, β- and γ-subunits, respectively. Approximately 120 μg of the purified α-subunit was dialysed against water, lyophilized and dissolved in 830 μl of 20 mM Tris-acetate buffer, *p*H 7.8, containing 2 mM $CaCl_2$. TPCK-treated trypsin (Worthington) was added at a transducin α-subunit/trypsin ratio of 30 (w/w). After incubation at 37 °C for 12 h, a further identical aliquot of TPCK-treated trypsin was added, and the incubation was continued for an additional 12 h.

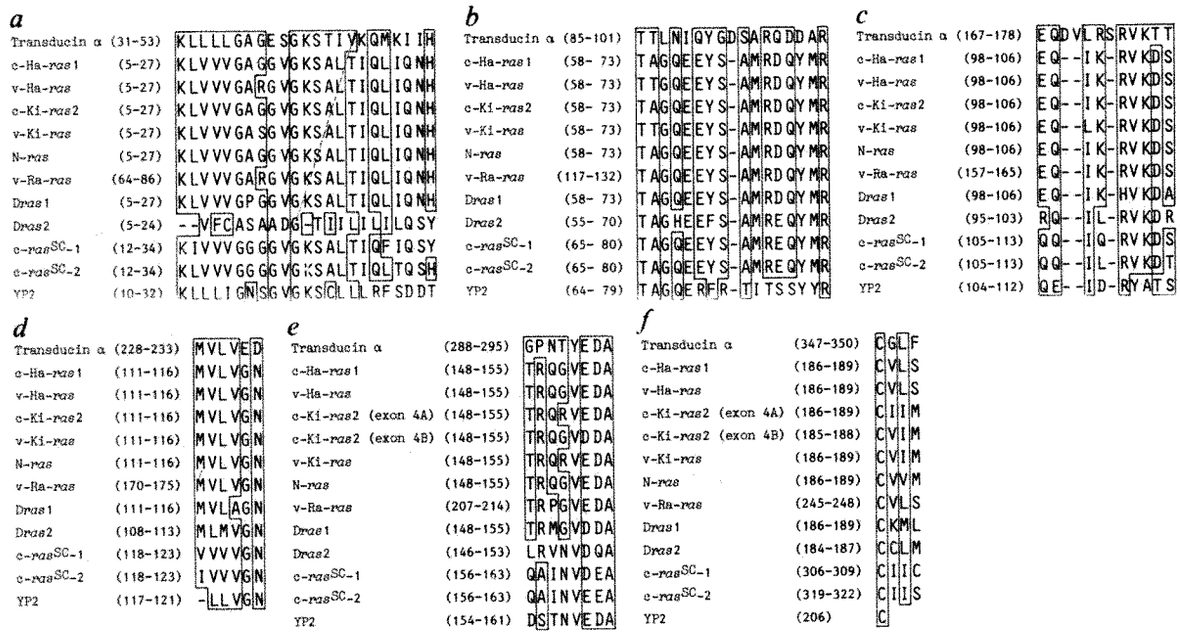

Fig. 4 Amino-acid sequence homology in different regions (*a*–*f*) between the transducin α-subunit and *ras* proteins. The sequences of the *ras* gene products have been taken from the literature: c-Ha-*ras*1 (ref. 46); v-Ha-*ras* (ref. 47); c-Ki-*ras*2 (ref. 25); v-Ki-*ras* (ref. 48); N-*ras* (ref. 26); v-Ra-*ras* (ref. 49); D*ras*1 and D*ras*2 (ref. 50); c-ras^{SC}-1 (refs 51, 52); c-ras^{SC}-2 (ref. 52); YP2 (ref. 53). The one-letter amino-acid notation is used. Amino-acid residues are numbered beginning with the initiating methionine of the respective polypeptides, and the residues constituting each aligned sequence are indicated by their numbers. Identities or favoured substitutions, as compared with the residues of the transducin α-subunit, are boxed. Favoured substitutions are defined as pairs of residues belonging to one of the following groups: S, T, P, A and G; N, D, E and Q; H, R and K; M, I, L and V; F, Y and W (ref. 54). Gaps (-) have been inserted to achieve maximum homology. In *e* and *f*, both the sequences encoded by exon 4A and exon 4B of c-Ki-*ras*2 are given.

Partial amino-acid sequences of the bovine transducin α-subunit reported recently by Hurley *et al.*[34] correspond, with some undetermined residues, to residues 19-51, 205-226 and 311-350 of our deduced amino-acid sequence. These authors have also noted the sequence homology between the transducin α-subunit and *ras* proteins in the region surrounding Gly 12 of p21.

We thank Drs Paul Berg and Hiroto Okayama for donating their high-efficiency cloning system and Dr Takashi Miyata and Mr Hiroyuki Toh for computer analysis. This investigation was supported in part by research grants from the Ministry of Education, Science and Culture of Japan, the Mitsubishi Foundation and the Japanese Foundation of Metabolism and Diseases.

Translocation of vesicles from squid axoplasm on flagellar microtubules

Susan P. Gilbert, Robert D. Allen & Roger D. Sloboda*

Department of Biological Sciences, Dartmouth College, Hanover, New Hampshire 03755, USA, and Marine Biological Laboratory, Woods Hole, Massachusetts 02543, USA

Directed intracellular particle movement is a fundamental process characteristic of all cells. During fast axonal transport, membranous organelles move at rapid rates, from 1 to 5 $\mu m\ s^{-1}$, in either the orthograde or retrograde direction along the neurone and can traverse distances as long as 1 m (for reviews, see refs 1–3). Recent studies indicate that this extreme example of intracellular motility can occur along single microtubules[4], but the molecules generating the motile force have not been identified or localized. It is not known whether the force-transducing 'motor' is associated with the moving particle or with the microtubule lattice. To distinguish between these hypotheses and to characterize the membrane–cytoskeletal interactions that occur during vesicle translocations, we have developed a reconstituted model for microtubule-based motility. We isolated axoplasmic vesicles from the giant axon of the squid *Loligo pealei* as described previously[5]. The vesicles (35–475 nm in diameter) were then added to axonemes of *Arbacia punctulata* spermatozoa that served as a source of microtubules. Axonemes were used because the tubulin subunit lattice of the A-subfibre of a given outer doublet is the same as the subunit lattice of neuronal microtubules along which motility occurs[6,7]. Moreover, all the microtubules of a single axoneme show the same structural polarity[8–10], indicating that the axoneme represents an oriented microtubule substrate. Here we demonstrate that vesicle motility is ATP-dependent, that it is not mediated by the flagellar force-transducing molecule dynein and that the direction of movement is not specified by microtubule polarity.

* To whom correspondence should be addressed.

When axoplasmic vesicles are added to flagellar microtubules in the presence of ATP, the vesicles move along the axonemal microtubules in either direction on a single axoneme. Figure 1*a–c* shows a vesicle (arrowhead) that has moved to the end of the axoneme and has remained attached on reaching the end. Figure 1*d–f* shows another vesicle that became associated with the same axoneme 8 minutes later, and the vesicle travelled in the opposite direction to that shown in *a–c*. The axonemes used in Fig. 1 were prepared from *Arbacia* spermatozoa by dialysis against low ionic strength Tris-EDTA buffer to remove the dynein arms[11]. SDS-polyacrylamide gel electrophoresis (Fig. 2) demonstrates that the dynein has been removed from the axonemes shown in Fig. 1. (Figure 2*d* shows the polypeptide profile of the axonemes before Tris-EDTA dialysis; lane *e* shows these axonemes after the dialysis, whereas lane *f* shows the proteins removed from the axonemes by the dialysis treatment.) These data demonstrate that the axonemes supporting vesicle motility lack dynein, the flagellar force-transducing molecule.

To examine the vesicle–microtubule interaction illustrated in Fig. 1 at higher resolution, a sample of axonemes and associated vesicles was fixed and prepared for thin-section electron microscopy (Fig. 3). The vesicle in Fig. 3*a* is in association with an axoneme; *b* illustrates a representative field of axonemes and a vesicle attached to a microtubule. Figure 3*c* shows that the vesicle membrane contacts the microtubule by crossbridging filaments. The distance between the crosslinks varies from 14 to 20 nm. Those segments of microtubules that are not in association with a vesicle lack these filamentous crosslinks. The other projections seen on the axonemal microtubules have the periodicity and appearance of radial spokes[12] and are unaffected by the low ionic strength dialysis that removes the dynein arms. Both the crossbridging filaments and the axonemal projections lack the tilt and periodicity (24 nm) expected for dynein. The sample used to generate Fig. 3 was obtained from the same axoneme/vesicle preparation as in Fig. 1. For electron microscopy, however, axonemes and vesicles were combined and fixed in solution. Thus, although Fig. 3 shows apparent inter-

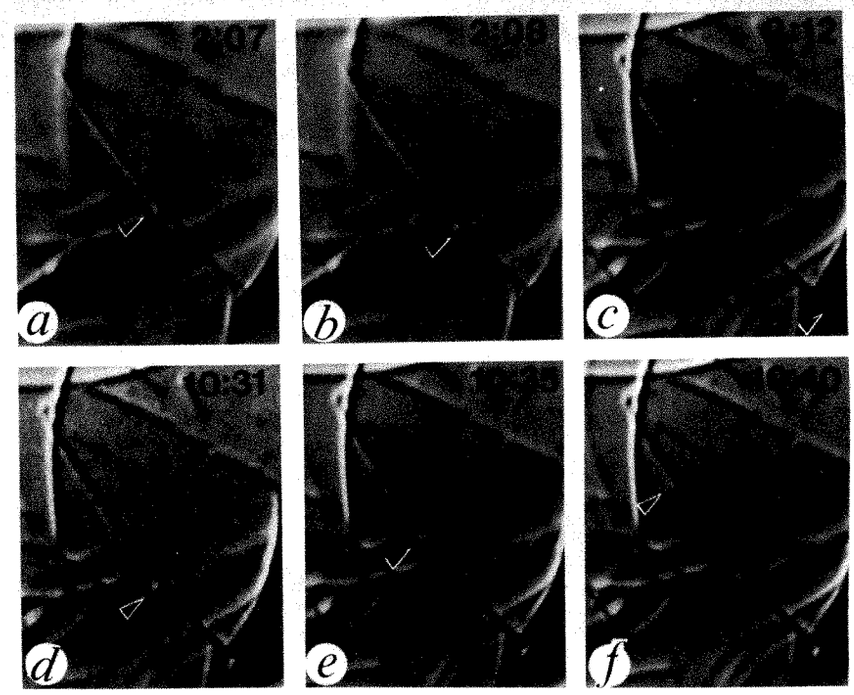

Fig. 1 Video micrograph of two vesicles moving on flagella axonemal microtubules in the absence of flagellar dynein. The sequence in *a–c* demonstrates a vesicle (arrowhead) that became attached to the axoneme at ~2 min after the vesicles were added to the axonemal microtubules. The sequence in *d–f* shows another vesicle (arrowhead) that became attached to the same axoneme 8 min later and moved in the opposite direction. The time (min:s) of each photograph of the video record is indicated. Scale bar, 1.2 μm.

Methods. Axonemal microtubules were prepared from *Arbacia* spermatozoa and dialysed against 1 mM Tris-HCl *p*H 8.0, 0.1 mM EDTA, 0.1% 2-mercaptoethanol to remove the dynein[11]. The axonemes were collected by centrifugation and washed 2–3 times in HEPES buffer (10 mM HEPES *p*H 7.0, 0.1 M KCl, 5 mM $MgSO_4$, 0.5 mM EDTA, 1 mM dithiothreitol). Washed axonemes were allowed to settle on a no. 0 coverslip and any unattached axonemes were removed by washing with the HEPES buffer. The preparation was covered with a second coverslip and transferred to the microscope for observation. Axoplasmic vesicles were isolated from the giant axon of the squid *Loligo pealei* using discontinuous sucrose gradient centrifugation as described previously[5]. These vesicles in buffer (0.3 M sucrose, 100 mM KCl, 10 mM $MgCl_2$, 1 mM EGTA, 1 mM ATP, 1 mM phenylmethylsulphonyl fluoride, 10 mM imidazole, *p*H 7.4) were added at the edge of the coverslip 'sandwich' containing attached axonemes and washed across the preparation by absorbing buffer with filter paper at the opposite side of the coverslip. Observations of the vesicle addition and of the vesicle movement were made by video-enhanced contrast differential interference contrast microscopy[18].

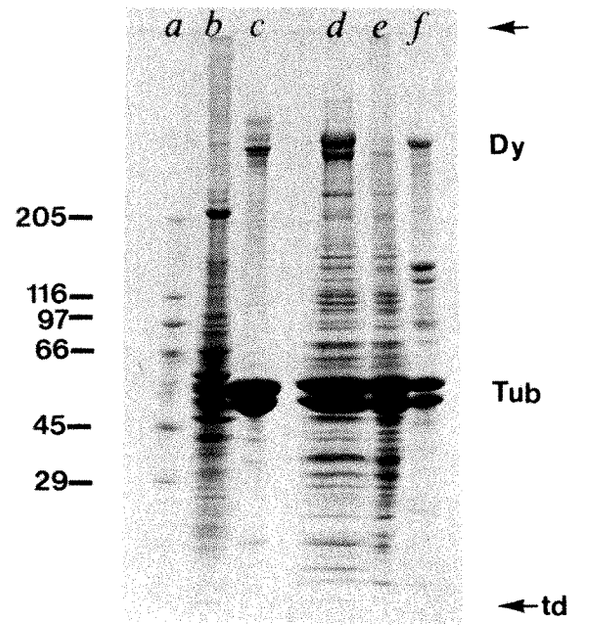

Fig. 2 SDS-polyacrylamide gel electrophoretic analysis of the protein composition of the axonemal microtubule preparation. Lanes *a*, *b* and *c* show various standards: *a*, relative molecular mass markers ($\times 10^{-3}$); *b*, squid axoplasm; *c*, purified mammalian brain microtubules. Lane *d* demonstrates the polypeptide composition of the axoneme preparation before the Tris-EDTA dialysis; lane *e*, the axonemes after dialysis and centrifugation, showing the loss of dynein (Dy) from the axonemal microtubules. (This sample (lane *e*) is from the same preparation as that used as the source of axonemes in Fig. 1.) Lane *f* shows the proteins removed from the axonemes by the dialysis step. Arrows indicate the top and bottom of the 3–15% acrylamide/12–48% urea linear gradient slab gel, using the buffer formulation of Laemmli[19] and stained for protein with Coomassie brilliant blue. Tub, tubulin; td, tracking dye.

action between a moving vesicle and an axoneme, we did not determine whether this vesicle was moving at the time of fixation.

We have found that axoplasmic vesicles move along: (1) outer doublets; (2) outer doublets treated with 0.5 M KCl to remove the outer dynein arms[13]; and (3) axonemes dialysed against Tris-EDTA to remove both the outer and inner dynein arms[11], but they do not move along intact flagella (that is, axonemes with the flagellar membrane present) or on glass fibres. Moreover, neither large unilamellar liposomes (100–400 nm in diameter; phosphatidylserine/phosphatidylcholine, 2:1) nor microspheres (200 and 400 nm in diameter) move along axonemes in the buffer that supports vesicle movement. Axonemes without added vesicles never demonstrate particle movement in the presence of ATP.

Rates of vesicle movement on axonemes subjected to various treatments were quantitated from video records[5]. Figure 4 illustrates similar rates of vesicle movement in three different axonemal preparations. The rates in *a* describe vesicles moving on outer doublets. The outer doublets were prepared by treating axonemes with trypsin to hydrolyse the nexin links, followed by reactivation with ATP to cause the microtubule outer doublets to slide relative to one another[14,15]. This results in the loss of the axonemal 9+2 configuration, but the dynein arms remain intact. The axonemal preparation in Fig. 4*b* was obtained by treating outer doublets (isolated as described for *a*) with 0.5 M KCl to remove the outer dynein arms[13]. The axonemes of Fig. 4*c* were dialysed against low ionic strength Tris-EDTA to remove both the outer and inner dynein arms[11].

Vesicles were observed to move in both directions on a single axoneme (Fig. 1). These observations indicate that the polarity of the microtubule did not dictate the directionality of vesicle movement because all the microtubules of a single axoneme have the same polarity[8–10]. Most vesicles do not change their direction of travel once in association with the axoneme, although we observed one vesicle that stopped and changed direction of translocation along the axoneme and some vesicles that changed from one axoneme to another and continued moving. However, the rates of movement were the same both for a vesicle that moved on two different axonemes and for several vesicles on the same axoneme. Furthermore, experiments

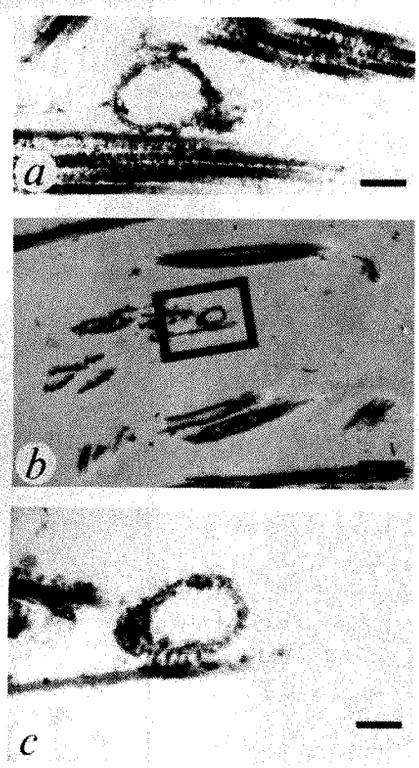

Fig. 3 Transmission electron micrograph illustrating vesicle association with axonemal microtubules. *a*, The vesicle (230 × 346 nm) illustrated is in contact with an axoneme. *b*, A typical field of axonemes with one vesicle in association with an axonemal microtubule. *c*, Higher magnification of the area enclosed in the rectangle in *b*. The vesicle (180 × 309 nm) is in association with an axonemal microtubule (24 nm) and seems to be attached by cross-bridging filaments; the spacing between the filaments is 14–20 nm. **Methods.** Vesicles and axonemes were prepared as described in Fig. 1 legend. Vesicles in buffer were added to axonemes and incubated for 5 min to allow vesicles to associate with axonemal microtubules. The preparation was fixed in 2% glutaraldehyde, 1% tannic acid, 1 mM $MgSO_4$, 0.1 M sodium phosphate buffer, *p*H 6.8 at 4 °C and post-fixed in 1% osmium tetroxide at 4 °C. The sample was dehydrated in ethanol, transferred through three changes of propylene oxide and embedded in LX-112 (Ladd Research Industries, Burlington, Vermont). Thin sections (60–70 nm) were stained with saturated aqueous uranyl acetate followed by lead citrate[20] and observed with a JEOL 100CX electron microscope at an accelerating voltage of 60 kV. *a*, Scale bar 150 nm; *b*, scale bar 500 nm; *c*, scale bar 100 nm.

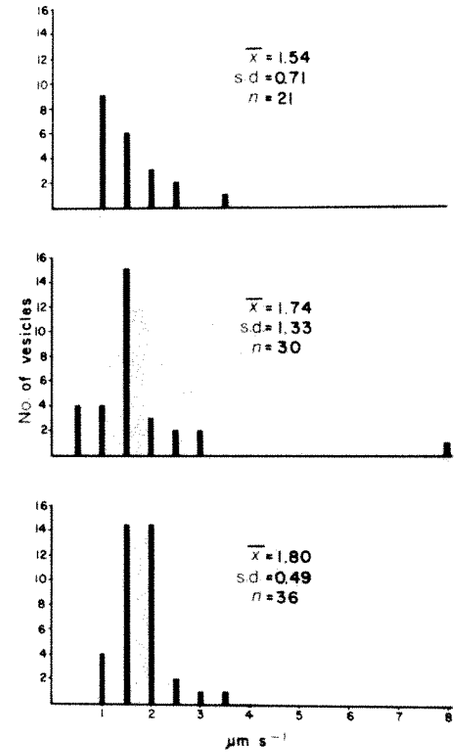

Fig. 4 Rates of vesicle movement on axonemal microtubules. *a*, Rates of vesicle movement occurring on axonemal outer doublet microtubules obtained by treating axonemes with trypsin followed by soybean trypsin inhibitor and reactivation with ATP. This treatment caused the outer doublet microtubules to slide apart out of the normal 9 + 2 configuration of the axoneme[14]. *b*, Rates of movement of vesicles on outer doublets obtained as in *a*, followed by treatment with 0.5 M KCl to remove the outer dynein arms[13]. *c*, Rates of movement of vesicles on intact axonemes dialysed against Tris-EDTA to remove the outer and inner dynein arms[11]. The three mean rates ($\bar{x}$) are not significantly different at a *P* of 0.05 as determined by either Student's *t*-test or Mann–Whitney *U* test. $\bar{x}$, Mean; s.d., standard deviation; *n*, sample size.

designed to test the competency of axonemes to support vesicle motility demonstrate that all axonemes tested support vesicle movement.

The results presented here demonstrate clearly that vesicles from squid axoplasm move on flagellar axonemal microtubules at the same rate in the presence or absence of flagellar dynein. Thus, vesicle motility is not mediated by the axonemal force-generating molecule dynein. In addition, the vesicle motility seems to be a different phenomenon from that studied by Bloodgood *et al.* in which polystyrene microspheres move on *Chlamydomonas* flagella[16,17]. The ATPase mediating the motility of microspheres on *Chlamydomonas* flagella demonstrates a strict dependence on both the flagellar membrane and Ca^{2+}. In contrast, axoplasmic vesicles do not move on intact flagella (that is, axonemes with membrane in place); furthermore, vesicle motility on axonemal microtubules occurs in the presence of 1 mM EGTA (that is, in the absence of calcium). The results presented here, when taken together with those of Gilbert and Sloboda[5], suggest that key vesicle surface proteins interact with the microtubule to effect vesicle movement. However, it is possible that there is an as yet uncharacterized ATPase associated with the axoneme that remains bound under conditions that remove flagellar dynein from axonemal microtubules. Alternatively, a soluble axoplasmic ATPase not associated with the membrane may co-purify with the vesicles and mediate vesicle movement. The results reported here do not distinguish between these possibilities, but rather present a rapid *in vitro* motility assay that may be used to evaluate microtubule-dependent motility. This model system will allow vesicle characteristics to be manipulated experimentally to localize and characterize the force-transducing molecules involved in fast axonal transport.

We thank Dr Robert H. Gross for the gift of liposomes. This research was supported by grants to R.D.S. (Muscular Dystrophy Association; NSF PCM 80-21976) and S.P.G. (Sigma Xi Grant-in-Aid and Albert Cass Traveling Fellowship). The microscope was provided by a grant to R.D.A. (Rowland Foundation). S.P.G. is a graduate student at Dartmouth College supported by a R. Mellville Cramer Graduate Fellowship and by NIH-NINCDS grant NS19962 to R.D.A.

A gelsolin-like Ca^{2+}-dependent actin-binding domain in villin

Paul Matsudaira*, Ross Jakes & John E. Walker

Medical Research Council, Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH, UK

Villin is an actin-binding protein of relative molecular mass (M_r) 95,000 found in the core bundle of microfilaments in brush border microvilli from intestine[1-3]. In physiological calcium concentrations (<1 μM), villin crosslinks actin filaments into bundles. However, in free calcium concentrations (>1 μM), villin severs actin filaments into short pieces[3-5]. To understand how villin can sever and bundle actin filaments, we are studying the molecular basis of villin–actin binding interactions by identifying important actin-binding domains in villin. Here, we report the purification and preliminary characterization of a 44,000-M_r fragment of villin which contains a calcium-dependent actin-severing activity. In addition, the partial amino-acid sequence from the amino terminus of this fragment reveals homology with a 16-residue region near the amino terminus[6] of gelsolin, an actin-severing protein found in many cells[7-9] and sera[10-12]. The sequence homology suggests a common structural basis for the calcium-regulated actin-severing properties shared by villin and gelsolin.

Glenney and co-workers[13,14] used V-8 protease to cleave villin into a 90,000-M_r amino-terminal fragment (villin core) and an 8,500-M_r carboxy-terminal fragment (villin headpiece) (Fig. 4*c*). Using electron microscopy, viscometry and pelleting assays, they showed that villin core retained the calcium-dependent actin-severing activity but lost the bundling activity of the intact villin molecule. In comparison, villin headpiece, independent of calcium, could bind but not bundle or sever actin filaments[13-15]. More recently, Hesterberg and Weber[16,17] identified one non-exchangeable and two exchangeable (with micromolar dissociation constants) calcium-binding sites in villin. One of the exchangeable sites was located in villin headpiece and the other two sites in villin core. We have used trypsin and other proteases to determine whether the calcium-dependent severing activity of villin can be localized to a fragment smaller than villin core. Trypsin cleaved villin into two fragments[18] of M_r 44,000 and 51,000 (named 44T and 51T, respectively, Fig. 1*a*). The time course of appearance of 44T and 51T (Fig. 1*b*) shows that both fragments are produced at similar rates and suggests that trypsin cleaves villin near the middle of the molecule. Digests for longer times or at higher trypsin/villin ratios caused further degradation of 51T while 44T remained stable to proteolysis. The instability of 51T relative to 44T explains the lower accumulation of 51T during proteolysis.

Villin fragments which retain calcium-regulated actin-binding activity were identified using the ^{125}I-actin gel overlay assay devised by Snabes and co-workers[19,20]. (They used this assay to identify gelsolin-like proteins in a variety of other cells and tissues.) In our experiments (Fig. 2), the ^{125}I-actin probe bound villin and 44T only in the presence of calcium; 51T did not bind actin in either calcium or EGTA. Thus, a calcium-regulated

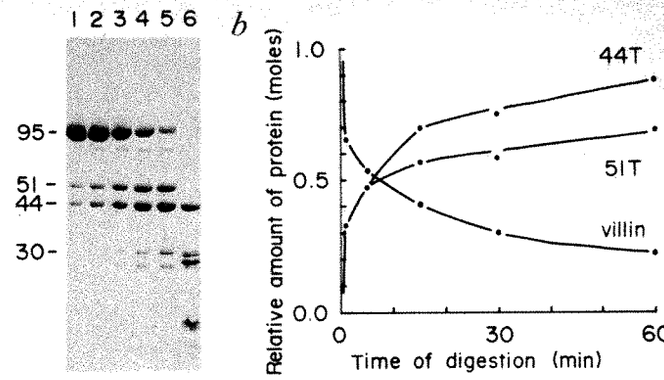

Fig. 1 Trypsin cleavage of villin. ***a***, Trypsin cleaves villin, M_r 95,000, into two major peptides of M_r 44,000 and 51,000. Lanes 1-6, digestion after 1, 5, 15, 30, 60 and 135 min, respectively. Trypsin, 5 mg ml^{-1} in 0.1 M Tris *p*H 7.5, 20 mM $CaCl_2$, was purified by affinity chromatography to soybean trypsin inhibitor coupled to Sepharose 4B. The column was washed with tryptamine (5 mg ml^{-1} in the Tris-$CaCl_2$ buffer) to remove chymotrypsin. Trypsin was eluted from the column with 3 mM HCl, 10 mM $CaCl_2$ and stored at −20 °C. Villin (5 mg ml^{-1}), purified using the method of Bretscher and Weber[3], in digest buffer (50 mM NaCl, 1 mM $MgCl_2$, 0.1 mM EGTA, 10 mM PIPES *p*H 7.0), was cleaved by trypsin at room temperature at a 1:5,000 (wt/wt) ratio of trypsin/villin. The digest was quenched with phenylmethylsulphonyl fluoride (PMSF) to 0.1 mM after 1, 5, 15, 30 and 60 min (lanes 1-5). Another aliquot of villin was digested at 1 : 500 for 135 min (lane 6). The digests were mixed with SDS sample buffer and electrophoresed[31] on 7-25% microslab gels[32]. ***b***, The amount of the two villin tryptic fragments increases with time at similar rates. The gels of the trypsin digest were measured by densitometry and the peaks cut out and weighed. The weights of the peaks were converted to moles of peptide assuming equal dye binding. The amount of peptide present was plotted as a function of time of digestion.

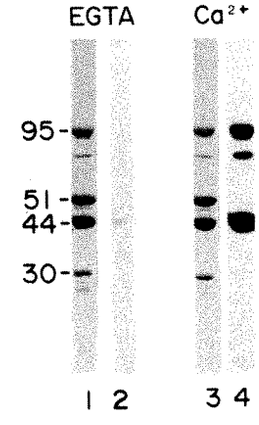

Fig. 2 Identification of calcium-dependent actin-binding fragments by a ^{125}I-actin gel overlay assay[19]. SDS gels of incomplete villin digests were incubated with ^{125}I-actin in 1 mM EGTA (lane 1) or 0.5 mM $CaCl_2$ (lane 3). Their corresponding autoradiograms (lanes 2 and 4) show only binding in calcium to villin, 44T and an 80,000-M_r contaminant.
Methods. An incomplete tryptic digest of villin was electrophoresed on SDS microslab gels and processed for actin binding. Duplicate samples were electrophoresed on one gel. The gels were fixed in 50% methanol, 10% acetic acid for 15 min, incubated in 10% ethanol for 2 h and then in phosphate-buffered saline (PBS) for 2 h, all at room temperature. After incubating overnight at 4 °C or for 2 h at room temperature with ^{125}I-actin (10,000 c.p.m. ml^{-1}, 100,000 c.p.m. total) in either 0.5 mM $CaCl_2$ or 1 mM EGTA in PBS, the gels were washed, stained, destained and dried. The dried gels were then autoradiographed for 8-36 h at −70 °C in cassettes fitted with Cronex intensifying screens.

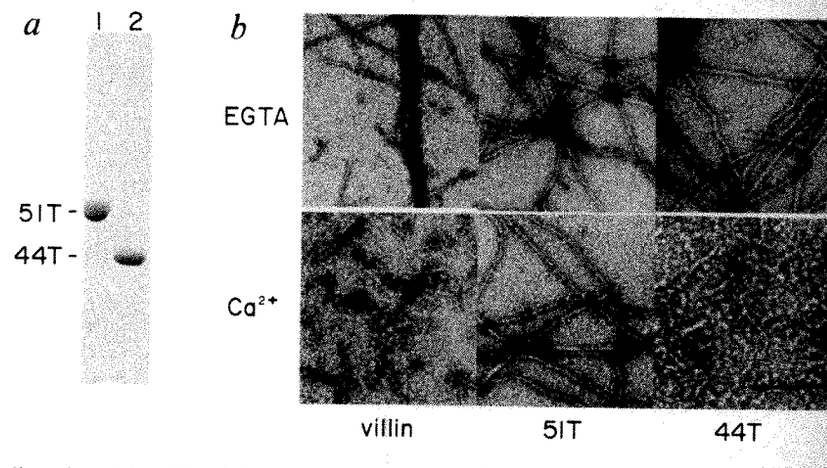

Fig. 3 Identification of the 44T and 51T actin-binding activities. *a*, The gel of the 51T (lane 1) and 44T (lane 2) fragments after purification over DEAE and Affi-Gel Blue chromatography. *b*, Electron microscopy of F-actin mixed with villin, 44T or 51T fragments. In EGTA (top panel), villin bundles filaments while 44T and 51T have no effect on actin filament organization. In calcium (bottom panel), 44T and villin both sever filaments into short pieces. In these conditions, 51T has no effect on actin filaments. Scale bar, 100 nm.

Methods. *a*, 44T and 51T purification. The villin digest was loaded onto DEAE-Sephacel (10 ml bed volume) previously equilibrated in digest buffer. The bound protein was eluted by a 25–250 mM NaCl gradient. The major peak eluted at 125 mM NaCl and contained 51T. The 51T fractions were made 10 mM with 2-[*N*-morpholino]ethane sulphonic acid (MES), the *p*H adjusted to 5.0 and loaded onto an Affi-Gel Blue (Bio-Rad, 10 ml bed volume) column equilibrated with 10 mM MES *p*H 5.0. The column was developed with a 0–0.5 M NaCl gradient in 10 mM MES. The major peak contained only 51T and was concentrated against solid sucrose, dialysed against 50% glycerol, 100 mM NaCl, 0.1 mM EGTA, 10 mM imidazole and then stored at −20 °C. 44T does not bind DEAE-Sephacel in digest buffer. The flow-through fraction from the DEAE column was collected and loaded immediately onto Affi-Gel Blue (10 ml bed volume) which had been previously equilibrated with digest buffer. The column was eluted with a 0–1 M NaCl gradient. The major peak which contained 44T was concentrated with sucrose and stored as described above. All steps were performed at 4 °C. Protein concentrations were measured using a modified Lowry method[33]. The purified fragments were electrophoresed on SDS gels to check for purity. A typical preparation yielded 20 mg of 44T and 7 mg of 51T from 50 mg of villin. *b*, The purified fragments were mixed with rabbit skeletal muscle F-actin (2 μM final concentration) at a 1:20 molar ratio in 150 mM NaCl, 1 mM $MgCl_2$, 10 mM PIPES *p*H 7.0 and with either 0.1 mM $CaCl_2$ or 0.1 mM EGTA for 30 min at room temperature. The samples were applied directly to carbon films on 400-mesh grids, rinsed with buffer, negatively stained with 2% uranyl acetate and then examined in the electron microscope. The micrographs were printed to the same final magnification.

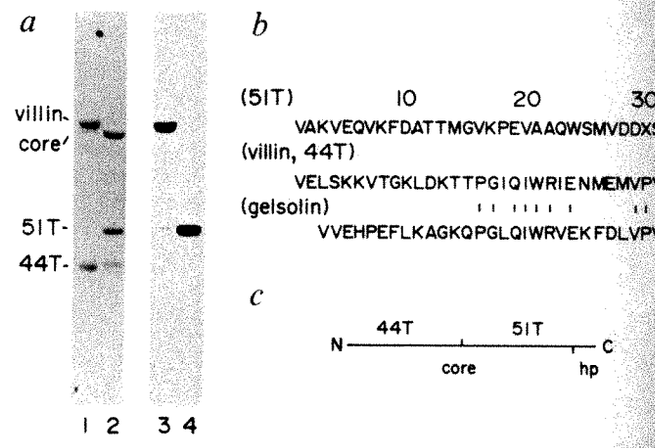

Fig. 4 Localization of the 44T and 51T fragments in villin. *a*, Purified villin, 44T (lane 1), villin core and 51T (lane 2) were electrophoresed on 10% microslab gels and then immunoblotted with a rabbit polyclonal antiserum (R200.2) raised against purified villin headpiece (lanes 3, 4). The blot shows that the headpiece antiserum recognizes villin (lane 3), villin headpiece (not shown) and 51T (lane 4), but not villin core (lane 4) or 44T (lane 3). *b*, Amino-acid sequence of the amino termini of villin, 44T and 51T compared with the amino terminus from rabbit macrophage gelsolin. Identical residues are indicated by vertical lines. *c*, Diagram of the locations of the 44T and 51T fragments relative to villin core and headpiece (hp).

Methods. *a*, Villin headpiece was purified from a V-8 digest of villin by a new method. Villin (5 mg ml^{-1} in digest buffer) was cleaved with *Staphylococcus aureus* protease (1:2,000 (w/w) enzyme/protein, 45 min, room temperature) and then applied to a DEAE-Sephacel column previously equilibrated in digest buffer. Villin headpiece does not bind to the column. The flow-through fraction was collected and applied to Affi-Gel Blue equilibrated with digest buffer. The column was eluted with a 0–1 M NaCl gradient in digest buffer. The headpiece-containing peak was pooled and concentrated as above. Villin core was eluted from the DEAE column with a 50–250 mM NaCl gradient in digest buffer. The peak containing villin core was pooled, concentrated against sucrose and then dialysed against 50% glycerol. Villin core was then stored at −20 °C. The identity of the headpiece fragment was checked by manually sequencing[34] the first four residues from the amino terminus of the fragment. Antisera were raised in rabbits by injecting 80 μg in complete Freund's adjuvent at multiple sites in the back, followed by subsequent injections at 2-week intervals in incomplete Freund's adjuvant. The rabbits were bled out at week 8. The titres of the antisera were quantified by enzyme-linked immunosorbent assay (ELISA). As judged by immunoblots and quantitative ELISA, the preimmune serum contained no detectable cross-reactivity against villin or its proteolytic fragments (not shown). The antiserum was characterized by immunoblotting[35] against villin, villin core, 44T and 51T after electrophoresis through microslab gels and electrophoretic transfer to nitrocellulose filters. The filters were blocked with 2% bovine serum albumin, incubated with antiserum at a 1:2,000 dilution and then with swine anti-rabbit IgG coupled to peroxidase (Dako) at a 1:400 dilution. The filters were developed with 4-chloro-1-naphthol. *b*, Purified villin, villin core, 44T and 51T (20 nmol each) were dialysed extensively against 5% formic acid, freeze-dried and subjected to the Edman degradation procedure using a modified Beckman 890B automated sequencer[36]. The phenylthiohydantoin (PTH) amino acids were analysed and identified by HPLC. The position and identity of each residue were determined at least twice by sequencing different preparations of protein. The villin sequences were checked for homology with protein sequences in the Doolittle data bank[37].

actin-binding domain seems to lie within a 44,000-M_r region of villin. The calcium dependence of binding rules out nonspecific binding as a possible explanation of our results. A minor contaminant (M_r 80,000) in the preparation also bound actin in a calcium-dependent manner, but its presence varied between experiments and was probably caused by a contaminating protease.

The actin-binding properties of 44T and 51T were then examined more directly by electron microscopy. Fragments were purified by ion-exchange and Affi-Gel Blue column chromatography. At neutral *p*H, 51T but not 44T binds to DEAE-Sephacel and thus the fragments can be easily separated. Each fragment separately can then be purified from minor contaminants by chromatography over Affi-Gel Blue columns. The purified fragments (Fig. 3*a*) were mixed with rabbit skeletal muscle actin at a 1:20 molar ratio in conditions[3–5] in which the intact villin molecule can bundle or fragment actin filaments (Fig. 3*b*). In EGTA, only villin bundled the actin filaments; the 44T and 51T

fragments had no effect on actin filament organization. In calcium, both villin and 44T shortened actin filaments to small pieces while 51T had no effect on actin filament integrity. Thus, electron microscopy directly confirms that the gel overlay assay has correctly identified 44T as a calcium-regulated actin-binding fragment of villin. Although we have not used more quantitative methods[15,21,22] to test whether 44T caps, nucleates and severs actin filaments in an identical manner to villin, the electron microscopic results suggest that severing can occur.

We surmised that 44T and 51T represent different regions of villin from the kinetics of their appearance during proteolysis. We then used antisera and protein sequence information to identify the location of these fragments more precisely within the villin molecule. We raised a polyclonal antiserum against the villin headpiece, which retains the carboxy terminus of villin[13,14]. Immunoblots of the villin proteolytic fragments showed that the antiserum recognized villin and 51T but not villin core or 44T (Fig. 4*a*), suggesting that 51T is associated with the carboxy-terminal half of villin while 44T could originate from the amino-terminal half. This was confirmed by sequencing the amino termini of villin, 51T and 44T (Fig. 4*b*). The first 30 residues in their sequences showed that villin and 44T share the same amino terminus and, therefore, 44T comprises the amino-terminal half of villin.

In addition, comparison of the villin amino-terminal sequence with the published amino-terminal sequence of rabbit macrophage gelsolin[6] revealed a short stretch (residues 16–31) of homology. This region shares 10 identical residues and 6 conserved replacements (Fig. 3*b*). Of these six replacements, five are consistent with a single base change. Although previous studies[1,9,20,23] have stressed that villin and gelsolin have different locations in cells, produce different peptide maps and elicit antisera which do not cross-react, our sequence information provides structural evidence that explains the similar actin-severing activities of these two proteins.

Our results (summarized in Fig. 4*c*) document a calcium-regulated actin-binding region which lies within the amino-terminal 44,000-M_r fragment of villin. As seen by electron microscopy, this fragment, like villin, villin core and gelsolin, seems to sever actin filaments into short pieces. The similarity between villin and gelsolin in their actin-severing activity as well as in the sequences of their amino termini suggests that villin could be a member of a related family of actin-severing proteins. This family could also include other proteins having M_rs and calcium-regulated actin-binding activities similar to the villin 44T domain, for example, severin from amoeba[24,25], fragmin and cap proteins from slime moulds[26–29], and an actin-binding protein from sea urchin eggs[30]. We speculate that these proteins could have sequence homology in regions corresponding to their actin- and calcium-binding sites.

We thank Drs A. Weeds, J. Kendrick-Jones and H. Huxley for their guidance and support, Mr B. Pope for instructing us on the gel overlay assay, and Dr C. Schutt for stimulating our interest in villin domains. P.M. was supported by an EMBO Long Term Fellowship and a British–American Heart Fellowship.

Local protein–DNA interactions may determine nucleosome positions on yeast plasmids

Fritz Thoma & Robert T. Simpson

Laboratory of Cellular and Developmental Biology, Bldg 6, Rm B1-26, National Institute of Arthritis, Diabetes and Digestive and Kidney Diseases, National Institutes of Health, Bethesda, Maryland 20205, USA

The structure of the nucleosome core particle, the basic structural subunit of chromatin, is well known[1]. Although nucleosomes often appear to be positioned randomly with respect to DNA sequences, in some cases they seem to occupy precisely defined positions on the DNA[2–8]. The yeast plasmid TRP1ARS1 contains three precisely positioned, stable nucleosomes, I, II and III, which are flanked by nuclease-sensitive regions.[5] Our aim in the present study was to determine whether the positions of these three nucleosomes relate to (1) protein–DNA interactions; (2) the limited space between nuclease-sensitive regions, which is just long enough to accommodate three yeast nucleosomes (that is, boundary conditions[9]); or (3) proximity to the putative origin of replication in one of the nuclease-sensitive regions[5,10]. We have tested these alternatives by analysing the positions of nucleosomes after insertion of various lengths of DNA into this region and assembly of chromatin *in vivo*. Our results suggest that specific protein–DNA interactions are the most likely determinants of these nucleosome positions.

We chose as the DNA to be inserted segments of a sea urchin 5S sequence which forms a positioned nucleosome *in vitro*[11]. An appropriate site at which to insert DNA fragments lies between the strong micrococcal nuclease cutting site in chromatin at position 1,022 and the strongly protected cutting site at 1,082 (Fig. 1). A shift of nucleosome I would prevent cutting at 1,022 and/or would expose the DNA cutting site at position 913. A shift of nucleosomes II and III would expose the cutting site at 1,341 or even that at 1,082. To obtain a suitable cloning site, we introduced a 10-base pair (bp) *Bam*HI linker into the *Nae*I site at position 1,069. Insertions of 75, 155 or 300 bp derived from the 5S gene were made (see Fig. 2). The plasmids derived in this way were transformed into yeast for assembly into chromatin. All constructs gave similar transformation efficiencies and yields in plasmid chromatin preparations; the inserts do not grossly interfere with either *TRP1* or *ARS1* function.

The plasmids were partially purified[5] and their structures analysed by micrococcal nuclease digestion. All plasmids had DNA packed in nucleosomes (not shown). To determine the locations of the nucleosomes, cutting sites were mapped using the indirect end-labelling method[4–6]. Mapping of the micrococcal nuclease cutting sites within the *TRP1* gene region showed

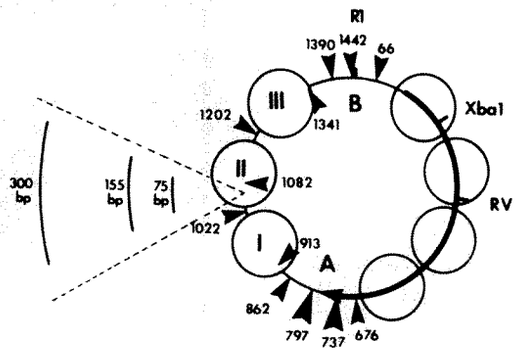

Fig. 1 Chromatin structure of the TRP1ARS1 plasmid: location of the inserts used to study nucleosome positioning. The detailed structure of TRP1ARS1 chromatin is shown[5], with the open reading frame for the *TRP1* gene indicated by the heavy arrow. Two nucleosome-containing regions are separated by two nuclease-sensitive regions A and B. A is located at the 3′ end of the *TRP1* gene and the putative origin of replication. B is located 5′ to the gene. The four nucleosomes on the *TRP1* are imprecisely positioned or unstable. Three stable nucleosomes (I, II and III) are precisely positioned on a sequence with unknown function (UNF). The cutting sites for micrococcal nuclease which are protected in TRP1ARS1 chromatin (913, 1,082 and 1,341) are shown inside the circle; cutting sites that are exposed in chromatin (676, 737, 797, 862, 1,022, 1,202, 1,390, 1,442 and 66) are shown on the outside. DNA fragments of 75, 155 or 300 bp were inserted between positions 1,069 and 1,070, as indicated. Nucleosomes I, II and III are characterized by protection of cutting sites at 913 and 1,082 and partial protection of the site at 1,341. Restriction enzymes used and their cutting sites are: *Eco*RI/1 (RI), *Xba*I/186 (XbaI), *Eco*RV/385 (RV).

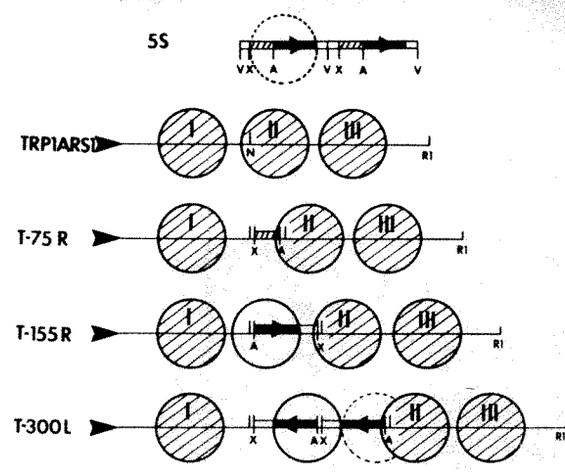

Fig. 2 5S rRNA gene region insertions in the TRP1ARS1 plasmid and nucleosome positions after reassembly in yeast. 5S: Two (of 18) tandemly repeated 190-bp fragments containing 5S sequences are shown. The position of the nucleosome assembled *in vitro*[11] is indicated by a dashed circle (from nucleotide 20 to 165 of the published sequence). TRP1ARS1: The positions of the three stable nucleosomes (I, II, III) on the TRP1ARS1 UNF region are shown as hatched circles. T-75R: Using two 10-bp *Bam*HI linkers, the 55 bp-long *Xmn*I/*Alu*I fragment of the 5S DNA (hatched box) was inserted in the same orientation as the *TRP1* gene. T-155R: Using two 10-bp *Bam*HI linkers, the 135 bp-long *Alu*I/*Xmn*I fragment of 5S DNA was inserted in the same orientation as the *TRP1* gene. T-300L: Using three *Bam*HI linkers, two 135 bp-long *Alu*I/*Xmn*I fragments of 5S DNA were integrated in tandem in the opposite orientation to the *TRP1* gene. The *Bam*HI linkers are shown as vertical ticks. Restriction sites are: V, *Ava*I; X, *Xmn*I; A, *Alu*I; RI, *Eco*RI; and N, *Nae*I. The large arrowhead on the left indicates the end of the *TRP1* gene.

Methods. The 1,453 bp-long TRP1ARS1 *Eco*RI fragment was inserted into the *Eco*RI site of a pBR322 derivative, from which the *Bam*HI site and all *Nae*I sites were deleted. A *Bam*HI linker was inserted into the *Nae*I site of the TRP1ARS1 sequence between nucleotides 1,069 and 1,070 to give plasmid pBRAT2. The insertions in the *Bam*HI site were derived from a segment of *Lytechinus variegatus* DNA containing the 5S rRNA gene[11]. A plasmid was constructed containing 18 tandemly repeated copies of a segment consisting of the DNA from nucleotide 1 to 178 of the published sequence[11], flanked by *Eco*RI and *Ava*I sites; the overall repeat length of the insert is 190 bp. The 55 bp-long *Xmn*I/*Alu*I fragment and the 135 bp-long *Alu*I/*Xmn*I fragment were gel-purified, attached to *Bam*HI linkers and inserted into pBRAT2. The modified TRP1ARS1 *Eco*RI fragments were gel-purified, circularized and used to transform yeast SC-3 (*mata ura3 his3 gal2 gal10 trp1*) obtained from L. W. Bergman (University of Maryland).

that all constructs had unstable nucleosomes similar to those of unmodified TRP1ARS1 (results not shown; see ref. 5). Figure 3 shows the mapping of the micrococcal nuclease cutting sites on chromatin and DNA, from the *Eco*RV site (position 385) counterclockwise using a 199-bp *Xba*I/*Eco*RV fragment as a probe. All the plasmids are strongly cut near the 3′ end of *TRP1*, around the putative origin of replication (arrowhead). Further, chromatin from all the plasmids is frequently cut between positions 1,341 and 66. We conclude that insertion of DNA affected neither the chromatin structure of *TRP1* nor the two nuclease-sensitive regions.

In chromatin incorporating plasmid T-75R, strong cutting was observed around position 1,022, accompanied by strong cutting in the inserted DNA region (open bracket in Fig. 3). Cutting sites in this region are weak in naked DNA controls and therefore exposed in chromatin. In the regions of chromatin from position 862 to 1,022, from the DNA insert to 1,202 and from 1,202 to 1,390, prominent naked DNA cutting sites (around 913, 1,082 and 1,341) are protected in a manner similar to that in TRP1ARS1 chromatin. We conclude that nucleosomes are formed at the same positions in the modified plasmid as in TRP1ARS1. The inserted DNA appears to be present as an exposed, long linker between two positioned nucleosomes, I and II (Fig. 2).

In T-155R chromatin, the nucleosomes at positions 862 to 1,022 and 1,202 to 1,390 again occupy identical locations in the derivative and parent plasmids (Fig. 3). Cutting of naked DNA at position 1,082 and at two positions in the insert is strong (relative to cutting at 1,202 and 1,022) while cutting at these three sites in chromatin is weak. As there are ~335 bp between cutting sites 1,022 and 1,202 (including the 155-bp insert), we suggest that there are two tightly packed nucleosomes positioned in this region (Fig. 2).

In T-300L chromatin, protection against micrococcal nuclase cutting between position 862 and 1,022, from the insert to 1,202, and from 1,202 to 1,390 indicates that nucleosomes I, II and III originally resident on the yeast sequences are positioned on the same sequences. The inserted DNA, however, appears to be cut through a nuclease-sensitive region of ~50 bp at one end and 90 bp at the other end. Strong cutting sites present on naked DNA in the insert are protected in chromatin, suggesting the presence of a single nucleosome on the 300-bp insert. To localize precisely this nucleosome on the inserted DNA, we have mapped micrococcal nuclease cutting sites clockwise from the *Xba*I site and counterclockwise from the *Eco*RV site at three levels of digestion. Cleavage sites at the boundaries of the linker DNAs are at positions 1,032 ± 15 and 1,122 ± 12 on one side and 1,266 ± 9 and 1,315 ± 15 on the other side (note that positions here refer to sites in T-300L, not TRP1ARS1). The protected region covers 144 bp between positions 1,122 and 1,266. With respect to the sea urchin 5S sequence, the nucleosome provides protection from nucleoside 162 on one repeat to 163 on the other (Fig. 2); the additional nucleosome assembled *in vivo* occupies a position on the 5S sequence which is similar to the position obtained in the *in vitro* reconstitution experiments[11].

The *ARS* function in the TRP1ARS1 fragment has been localized between positions 615 and 1,453 (ref. 10). We have

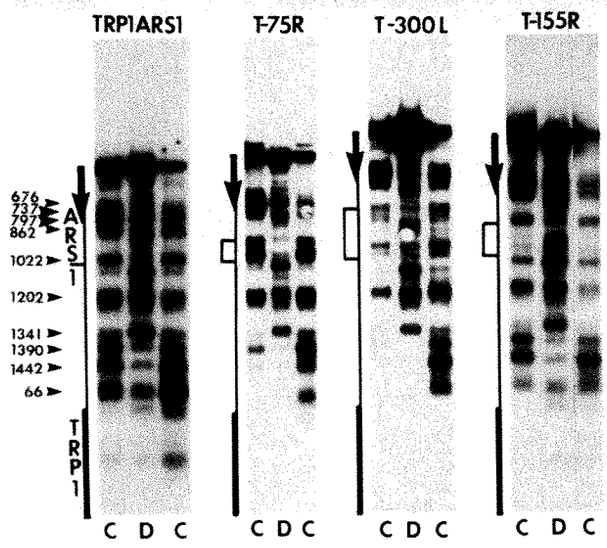

Fig. 3 Mapping of the micrococcal nuclease cutting sites on chromatin (C) and DNA (D) counterclockwise from the *Eco*RV site. TRP1ARS1: Mapping data and the mean cutting sites, indicated on the left-hand side, are taken from Thoma *et al.*[5], and serve as a standard. The position of the insertions is marked by a tick. T-75R, T-300L, T-155R: The positions of the inserted sequences are indicated by open boxes. The vertical arrow indicates the open reading frame of *TRP1*.

Methods. Preparation of plasmid chromatin and control DNA, digestion with micrococcal nuclease and mapping of the cutting sites were done in a similar way to that described by Thoma *et al.*[5]. Yeast cells were grown at 30 °C in minimal medium supplemented with uracil and histidine (0.67% yeast nitrogen base without amino acids (Difco), 2% dextrose, 20 g uracil per l, 20 g histidine per l) to an absorbance of 1-4 at 600 nm, washed twice with water and converted to spheroplasts using Zyolyase 60,000 (Kirin Breweries, Takasaki, Japan). The spheroplasts were washed in yeast wash buffer (40 mM K-phosphate *p*H 7.5, 1 M sorbitol, 1 mM phenylmethylsulphonyl fluoride (PMSF)) and lysed in buffer A (20 mM Tris-HCl *p*H 8, 150 mM NaCl, 5 mM KCl, 1 mM EDTA, 1 mM PMSF) containing 0.2% Triton X-100. The genomic chromatin was pelleted at 27,000 *g* at 0 °C for 30 min and the small contaminating material was removed by gel chromatography on Sephacryl S300 in buffer A. The plasmid chromatin eluted in the void volume and was pooled. DNA from one half of the chromatin pool was extracted using phenol, phenol/chloroform, and chloroform; RNA was digested with RNase A, and DNA was re-extracted as above and precipitated twice. Micrococcal nuclease digestions were done in buffer A supplemented with 5 mM $CaCl_2$ for 5 min at 37 °C using four different enzyme concentrations. To map the micrococcal nuclease cutting sites, DNA was extracted as above, cut with *Eco*RV, separated on 1% agarose gels in Tris-borate buffer containing ethidium bromide, blotted onto nitrocellulose, and hybridized to radioactively labelled *Xba*I/*Eco*RV fragments. The radioactive bands were detected using Kodak XAR-5 film.

shown that different fragments of DNA can be inserted at position 1,069 without disrupting *ARS* function. As the nucleosome between 862 and 1,022 in TRP1ARS1 is highly stable[5], we suggest that the functional *ARS* sequence lies in the nuclease-sensitive region A between 676 and 862, in analogy to simian virus 40, where the origin of replication is known to be in a nuclease-sensitive region[12].

We next consider the possible determinants of nucleosome positions. Insertion of 75–300 bp of DNA had no effect on the positions of nucleosomes I, II and III. Surprisingly, yeast prefers to assemble long linkers (75, 49, 90 bp), although on average the yeast micrococcal nuclease repeat length is ~160 bp[13], consistent with 145-bp nucleosome cores connected by ~15-bp core-to-core linkers.

One may ask whether nucleosome formation near the replication fork aligns or phases nucleosomes in positions which are determined by the location of the origin of replication. Although the precise location of the origin of replication and the nature of the replication process are unknown, the existence of variable-length linkers in T-75R and T-300L excludes the possibility that nucleosome positioning is a simple function of replication.

The existence of long linker DNA demonstrates that the yeast did not take the opportunity to rearrange or randomize its nucleosome positions; this observation excludes a simple boundary mechanism in which the positions of nucleosomes are determined by a statistical arrangement within limited space between two boundaries, regions which interact with other proteins to preclude nucleosome formation[9]. Although we must consider the possibility that the inserted DNA itself (particularly the DNA which exists as long linkers) may represent a boundary, this seems unlikely for the linkers in T-75R and T-300L. Thus, these sequences can associate with histones to form nucleosomes, that is, the X-A fragment in T-75R formed *in vitro*[11] and the sequences represented by both the open and black boxes in T-300L in the additional nucleosome formed *in vivo* (Fig. 2). As we have excluded the simple boundary mechanism and a replication-related mechanism, we conclude that local protein-DNA interactions, involving either histones *per se* or positioning proteins[14], probably determine the positions of these yeast nucleosomes.

The nucleosome formed on the 300-bp insert appears to occupy a position identical to that of the core particle assembled *in vitro*[11]. As only 90 bp of sequence are shared in the nucleosomes assembled *in vitro* and *in vivo*, we suggest that this sequence (*Alu*I site to position 162) must contain a nucleosome positioning signal. A similar conclusion has been reached in studies of the *in vitro* assembly of modified 5S fragments with histones, although *in vitro*, sequences to the left of the *Alu*I site serve a discriminatory function in phasing (P. FitzGerald and R.T.S., unpublished observations). As only histone-DNA interactions were necessary *in vitro* to position the nucleosome, we infer that, in yeast, histone-DNA interactions may be the dominant mechanism for positioning of this particular nucleosome *in vivo*. It is interesting that chicken erythrocyte histones were used for the *in vitro* experiments[11], therefore the positioning signal may be universal.

Whatever mechanisms are responsible for positioning of these nucleosomes, the fact that only one of the two positioning signals on the 5S DNA was used in T-300L (formation of the nucleosome indicated by the dashed circle in Fig. 2 did not occur), together with the observation that nucleosome II did not shift in T-75R or T-300L, suggests that a hierarchical array of positioning signals must exist. The signal for nucleosome II must be stronger than that for the 5S sequence.

We have shown that yeast and yeast plasmids can be used as an *in vivo* chromatin reassembly system for addressing questions relating to structure and function of nucleosomes *in vivo*. Although the present experiments have analysed structural changes only in circular plasmids, homologous recombination in yeast will allow the extension of such studies to the chromosome itself.

We thank our colleagues for criticisms and discussion, particularly David Pederson and Peter FitzGerald for comments on the manuscript and Joel Brubaker for plasmid construction and isolation.

Although techniques are available for the determination of the three-dimensional structure of biological specimens, for example scanning electron microscopy, they all have some serious drawback, such as low resolution, the requirement for crystals or for the sample to be analysed in a high vacuum. In an attempt to develop a technique for high-resolution three-dimensional structure analysis of non-crystalline biological material, we have tested the applicability of scanning tunnelling microscopy (STM), a method that has been used successfully in the analysis of metal and semiconductor surface structures[1–3]. We report here that scanning tunnelling electron microscopy can be used to determine the surface topography of biological specimens at atmospheric pressure and room temperature, giving a vertical resolution of the order of 1 Å. Our results show that quantum mechanical tunnelling of electrons through biological material is possible provided that the specimen is deposited on a conducting surface.

We have used a STM microscope similar to the one developed at the IBM Zürich Laboratory[1], but operated at air atmospheric pressure. The microscope works by scanning a metal tip of very small radius at a distance ~5–10 Å above the surface by means of three mutually perpendicular piezoelectric ceramics. In the constant-current mode, the tip–surface distance remains roughly constant during the scanning because of the extreme sensitivity of the tunnel current with respect to the tip–surface separation[4].

To proceed with the STM of biological samples, a flat conducting and structureless substrate was needed. This condition was satisfied by pyrolitic graphite (Fig. 1*a*), where a surface which is atomically flat on a ~2,000-Å range displays a step of monoatomic height. From this image, we could estimate the stability and resolution of our microscope to be ~1 Å of vertical resolution and ~5–10 Å of lateral resolution. These values were obtained at atmospheric pressure and room temperature.

We have analysed two types of of biological samples, both derived from bacteriophage ϕ29 particles. This small bacteriophage is composed of a prolate icosahedral head (415 × 315 Å) and a complex tail (410 Å long)[5,6]. Phage particles release their DNA and part of their neck–tail complexes when treated with EDTA[6]. The purified phage samples were diluted in 0.1% glycerol for examination by STM. A control experiment to check the influence of the 0.1% glycerol solution on the graphite surface demonstrates a noise level of the surface lines only slightly higher than that of the graphite substrate (Fig. 1*b*).

The phage-derived structures were allowed to air dry over an electron microscope grid and then stained to detect the degree of destruction provided by this drastic drying procedure. Figure 2*a* shows that phage particles (either with or without DNA) retained their characteristic gross morphology[5,6]. A parallel sample was then adhered to a surface of freshly cleaved graphite by drop deposition, allowed to air dry and then examined by STM.

Over a flat background (similar to that shown in Fig. 1*b*), a series of reproducible scans allow us to define objects (Fig. 2*b–d*). A comparison of these surface topographies with the electron micrographs of the phage-derived structures suggested that the STM topographic profiles could be correlated qualitatively with the general shape and dimensions of DNA-filled phage, empty head and empty phage particles. Flattening of the

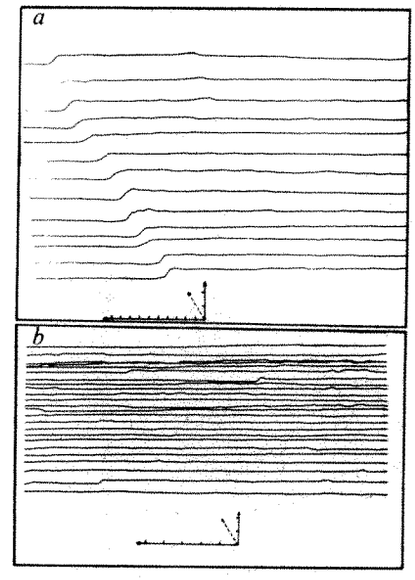

Fig. 1 *a*, STM topographic curves of a pyrolitic graphite surface cleaved in air, obtained at ambient pressure. Divisions on the axes are 10 Å apart. The scale along the *y*-axis (broken line) is not well determined. A step of height 7 Å corresponding to the lattice constant of graphite (6.708 Å) is clearly visible. *b*, STM topographic curves of a graphite surface covered with 0.2 M ammonium bicarbonate containing 0.1% glycerol used to deposit the bacteriophage-derived structures. Divisions on the axes are 50 Å. Note that the substrate is flat over the range ~1,000 Å.

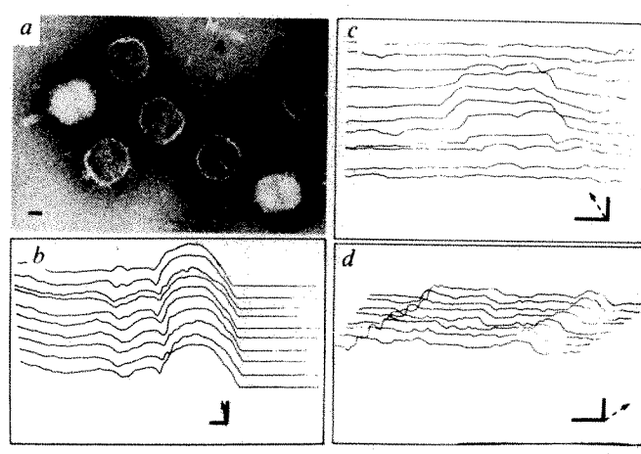

Fig. 2 *a*, Electron micrograph of various structures derived from bacteriophage ϕ29. Phage particles treated with EDTA[6] released their DNA and part of their neck–tail complexes. After partial purification of the empty head fraction, the material was diluted 10 times in 0.1% glycerol and allowed to air dry over a collodion–carbon-coated electron microscope grid. After drying, the sample was negatively stained with 2% uranyl acetate and observed by transmission electron microscopy. Numbers 1, 2 and 3 correspond, respectively, to DNA-filled phage particle, empty head and empty head with tail. Neck–tail complexes (number 4) can also be seen. Scale bars, 100 Å. *b–d*, STM surface profiles from a parallel sample dried over graphite. Profiles in *b* probably correspond to scans along the head–tail axis of a DNA-containing phage particle. Profiles in *c* can be correlated with the expected flattened structure obtained after air drying an empty capsid without tail. Profiles in *d* can be interpreted as scans along the head–tail axis of an empty phage particle with tail complex. Note that the height of the flattened head in *c* and *d* (~70 Å) is much smaller than in the case of the DNA-containing head shown in *b* (~200 Å) whereas the height of the tails in *b* and *d* is very similar (~75 Å).

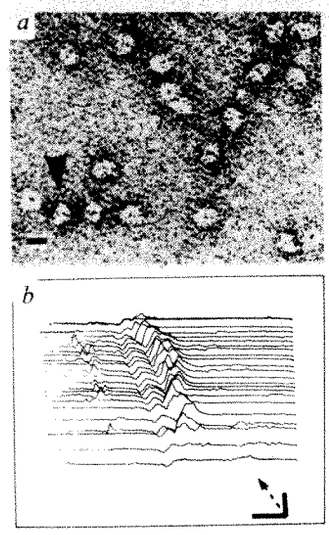

Fig. 3 *a*, Electron micrographs of the upper collar of bacteriophage ϕ29. The upper collar protein of phage ϕ29 was purified[8,9] and dialysed against 0.2 M ammonium bicarbonate containing 0.1% glycerol to prevent destruction during the air-drying procedure. This sample was negatively stained with 2% uranyl acetate and observed by transmission electron microscopy. The collars appear as circular structures with a hole in the centre. Occasional side views show a dumbbell shape with a hole running through the centre of the neck (arrowhead). Scale bar, 100 Å. *b*, STM surface topography curves obtained from a collar-containing sample deposited over graphite and air-dried. The scans show profiles of a structure (100 Å in diameter along the *x*-axis and 80–90 Å in height along the *z*-axis) that correlates with the collar structure inferred from the images shown in *a* (ref. 9).

air-dried specimens, commonly observed in all electron microscope methods[7], is also seen in the present experiments for empty viral heads (Fig. 2*c*, *d*). Repeated scans over the same area always showed very similar topography, implying that STM does not drastically alter the biological surface structure.

The second sample studied by STM was the oligomeric protein structure that forms the upper collar of ϕ29 (refs 8, 9). Transmission electron micrographs of this oligomer showed a circular front view (135 Å diameter) with a hole in the centre (Fig. 3*a*). Occasional side views showed that the oligomer has a dumbbell shape (125 Å on height). The collar sample was dialysed against 0.2 M ammonium bicarbonate (containing 0.1% glycerol) to remove salts and low-relative molecular mass components and then analysed by STM.

Over a general flat surface, some series of scans were observed that could be correlated with the presence of the phage collars (Fig. 3*b*): the more characteristic feature is a structure ~100 Å in diameter (*x*-axis) and 80–90 Å in height (*z*-axis) showing a hole in the centre, which is in good agreement with the structure of this collar observed by transmission electron microscopy[9] (Fig. 3*a*).

Most of the pictures presented were scanned insufficiently in the *y*-direction, which prevents the observation of the entire object. This limitation resulted from the difficulty in controlling the piezo movement in the slow direction (*y*-axis), because both piezo relaxation and external scanning may have a similar value.

We stress that we have obtained real corrugated structures in the STM of as much as 250 Å for an applied voltage of 0.4–0.8 eV, giving a tunnel current of 10 nA. Assuming an average tunnel area of 300 Å^2, as indicated by the experimental lateral resolution[4], an effective tunnel resistivity of ~1 Ω cm^{-1} is obtained. This resistivity is much too small for a single tunnel process over ~200 Å. We propose a transport mechanism to explain the effective conductivity of the biological material analysed by assuming the existence of regions where the electrons tunnel (conduction levels higher than the kinetic energy of the electrons) and regions where they propagate (conduction levels lower than the kinetic energy of the electrons). If such regions of tunnelling and propagation of electrons exist in the specimen, electrons can easily move by percolating in the propagating regions, whereas resonant tunnelling in the tunnel regions can substantially enhance the conductivity over single tunnel processes. Calculations on one-dimensional disordered systems show an enhancement of the conductivity[10]. We believe that both type of regions are provided by the different bonds and radicals existing in the protein of the biological material. More information will be provided in a forthcoming paper.

In conclusion, our results show that STM can be used to determine the surface topography of air-dried untreated biological specimens at atmospheric pressure and room temperature without altering the material. Real-space three-dimensional topographic profiles giving a vertical resolution of the order of 1 Å are obtained, which can be correlated in terms of size and shape with biological objects. In addition, STM can be used to determine the surface microstructure of other materials such as metals, semiconductors, thin films and polymers. The operation of the microscope at atmospheric pressure opens the possibility for investigation of the technological applications of these materials in such fields as metallurgy, microelectronics and catalysis.

We thank Professors N. Cabrera, C. López and S. Vieira for their support and Drs G. Ramírez, J. Jiménez and S. Ferrer for fruitful discussions. We also thank IBM, particularly Dr Herb Budd and V. Martínex for financial support, and the Ramón Areces Foundation and the Fondo de Investigaciones Sanitarias for partial financial support. This work was developed by a joint collaboration with the Centro de Investigación UAM-IBM.

ACADEMIC PRESS

Academic Press Journals . . . .

WASTE MANAGEMENT & RESEARCH
Editor: R. B. Dean
Ingeniørhuset, Vester Farimagsgade 29, DK-1606 Copenhagen V, Denmark.
Publication: Quarterly
Subscription: Volume 3, 1985,
£48.00 (U.K.)/$95.00 (overseas)

The aim of this journal is to satisfy the growing demand for essential information of practical application by those who are responsible for the management of both municipal and industrial waste. *Waste Management & Research* publishes from a broad cross section of researchers and workers in the field; from academic institutions, governments and the private sector. Recent papers include the following topics: city cleansing, studies of the effects of waste management practises, new technological developments, hazardous wastes, recycling, engineering and design.

JOURNAL OF APPLIED BIOCHEMISTRY
with special reference to biotechnology
Editor-in-Chief: P.N. Campbell
Courtauld Institute, The Middlesex Hospital, London.
Publication: Bimonthly
Subscription: Volume 7, 1985,
£50.00 (U.K.)/$70.00 (overseas)

This journal fills the need for a publication recording the results of biochemical research of an applied nature. Fundamental studies directly related to the design of new biotechnology, substantial improvements in biochemical processes, and the preparation, utilization, conversion, or application of biological materials are emphasized. The journal publishes the results of biotechnology that apply to many areas such as clinical chemistry, the food and beverage industry, the pharmaceutical industry, agriculture, medicine, energy production, fermentation technology and microbial processes, and enzyme technology.

HANDBOOK OF ENZYME BIOTECHNOLOGY, 2nd Edition

edited by **A. Wiseman,** *Department of Biochemistry, University of Surrey, Guildford*

Since the first edition of *Handbook of Enzyme Biotechnology* was published, almost a decade ago, many important advances have been made in this growing scientific discipline. This new book takes due account of these changes, recording up-to-date developments in research. As its predecessor, this book will have wide application, and will take its place as one of the most important books in this field.

Series: Enzyme Biotechnology

085312 420 5 458pp March'85 £42.50

Contents: PART A: Introduction to Principles; Large Scale Extraction and Purification of Enzymes and Other Proteins; Principles of Industrial Enzymology — Basis of Utilization of Soluble and Immobilized Enzymes in Industrial Processes; Principles of Immobilized Enzyme Reactor Technology, Including Enzyme Stabilization; Enzymes in Clinical Analysis — Principles; PART B: Introduction to Enzyme Utilization; Practical Aspects of Large-Scale Protein Purification; Applications of Enzymes in Industry; Data on Techniques of Enzyme Immobilization and Bioaffinity Procedures; Enzymes in Clinical Analysis — Data.

ACAROLOGY VI Volumes 1 and 2

by **D.A. Griffiths,** *Head of Storage Pests Department,* and **C.E. Bowman,** *Acarologist, both of Ministry of Agriculture, Fisheries and Food, Slough Laboratory, Berkshire*

Presents new areas of research often highlighting the availability of elegant new techniques in biochemistry, physiology and morphology. These techniques have been the basis for the advancement of knowledge on the physiology and structure of the *Acari*, where recent work on the nervous system and sense organs, on the integument, and on the structure and function of glandular systems, rivals comparable work on insects in its detail and sophistication.

085312 603 8 656pp July'84 Vol.1 £49.50
085312 604 6 660pp Dec'84 Vol.2 £49.50

BIOCHEMICAL EFFECTS OF DRUGS IN PREGNANCY

Volume 1: Drugs Active on the Nervous, Cardiovascular and Haemopoietic Systems Volume 2: Diuretics, Digestive and Pulmonary Tract Drugs, Hormones, Antihormones and Steroid Hormones; Analgesics, Metabolic Action Drugs, Antibiotics and Chemotherapeutic Substances, Vaccines and Sera.

by **A. Onnis,** and **P. Grella,** *both of University of Padua*
Translation Editor, **P.J. Lewis,** *formerly Department of Clinical Pharmacology, Royal Postgraduate Medical School, now Research Director, Merrell International, France*

This book takes a logical approach to the problem, in a two-volume investigation of all currently-known drugs used on both human beings and on animals.

The Ellis Horwood Series: Biochemistry and Pharmacology in Medicine and Neuroscience Series Editor: **J. de Belleroche,** *Charing Cross Hospital Medical School, London*

085312 519 0 412pp Oct'84 Vol.1 £45.00
085312 592 9 510pp Dec'84 Vol.2 £45.00

HANDBOOK OF CHEMICAL EQUILIBRIA IN ANALYTICAL CHEMISTRY

by **S. Kotrly,** *University of Chemical Technology, Pardubice,* and **L. Sucha,** *University of Chemical Technology, Prague.*

This concise, authoritative handbook on the art of using equilibrium data for solving practical problems in the laboratory will be useful to analytical chemists in industry, research and medicine. Designed essentially for practical purposes it presents a critical compilation of equilibrium data based on up-to-date research.

Ellis Horwood Series in Analytical Chemistry
Series Editors: **F.A. Chalmers** and **M. Masson,** *University of Aberdeen*

085312 107 9 414pp Feb'85 £45.00

FAULT AND FOLD TECTONICS

by **W. Jaroszewski,** *Faculty of Geology, University of Warsaw*

This most timely survey of fault and fold tectonics and associated problems takes into account the many important, rapid advances made in tectonic theory, an ever-widening field of study in geological research. It traces the main physical mechanisms producing macrostructural phenomena: and shows how these phenomena can be understood. The work will fill a gap in the literature, providing both academic and field geologists with a ready compendium of tectonic problems, contributing an understanding of structure-forming mechanisms in terms of other natural sciences, Physics in particular.

Ellis Horwood Series in Geology Series Editor: **Professor D.T. Donovan,** *University College, London*

SATELLITE OCEANOGRAPHY:

An Introduction for Oceanographers and Remote Sensing Scientists

by **I.S. Robinson,** *Department of Oceanography, University of Southampton*

This broad-ranging book bridges the void between brief review papers on oceanographic applications of remote sensing and detailed technical reports about sensors and satellites. The text fills this gap by providing marine scientists with a broad general introduction to the subject from first principles and a thorough explanation of the different techniques for applying satellite data in oceanography.
Pitching the academic level at postgraduate/undergraduate level, and assuming a general scientific training, Dr. Robinson introduces the subject from first principles, discussing central ideas and theories.

Series: Ellis Horwood Series in Marine Science

ORGANIC ANALYSIS USING ATOMIC ADSORPTION SPECTROMETRY

by **S.S.M. Hassan,** *Department of Chemistry, Faculty of Science, Ain Shams University, Cairo*

Various organic materials can be determined indirectly by atomic-adsorption spectrometry (AAS), the main advantage being the low limit of detection. This book, the first devoted to use of AAS in organic analysis, reflects the growing interest in this application. It surveys the basic principles, instrumentation and techniques, and gives an up-to-date review and critical evaluation of the methods developed, and details of selected and tested experimental procedures.

Nuts with everything

John Rivers

Health or Hoax? The Truth about Health Foods and Diets.
By Arnold E. Bender.
Elvendon Press, The Old Surgery, High Street, Goring-on-Thames, Reading, Berkshire, UK: 1985. Pp.184. £8.50.
The Penguin Encyclopaedia of Nutrition.
By John Yudkin.
Viking: 1985. Pp.431. £14.95, $20.
Diet-Related Diseases: The Modern Epidemic.
By Stephen Seely, David L.J. Freed, Gerald A. Silverstone and Vicky Rippere.
Croom Helm/Avi: 1985. Pp. 272. Hbk £19.95, $35; pbk £9.95.

THE dilemma of nutrition is not merely caught in these three books; it is writ large, as six authors wrestle with what nutritionists do and do not know, and, more importantly perhaps, with what almost everyone else seems so certain about. Each book has a different aim, and a very different style, but they share a common constituency of the layman, the undergraduate and the professional in search of diversion.

Professor Bender's book, a swingeing, shotgun attack on health foods and their purveyors, will clearly attract the greatest attention (an extract has already appeared in the *Daily Mail*). Although I have some reservations about it, a detailed dissection of health food mythology is long overdue and Bender provides this in a most entertaining style. The message of the book is neatly encapsulated in his opening contention, that there are no such things as health foods, there is merely an industry which sells them. Bender not only shows that the claims made for health food products have little or no scientific basis, he casts doubt on the motives, practices and business standards of the industry, concluding briefly with his own recommendations for a good diet. All this is done with gusto, employing a mixture of sarcasm, wit and his encyclopaedic knowledge of nutrition. But while I finished the book with my appetite whetted it was not satisfied: at times I was left wishing for more, or fuller, answers to some of the issues he raises, hoping that he might return to the attack at greater length after each skirmish; at others, in flat disagreement with some of his scientific assertions.

One issue touched on tantalizingly, but not fully explored, is the nature of the health food movement itself. With apparent relish, Bender quotes the views of a colleague who describes it as compounded of both cranks and swindlers "bent on the commercial exploitation of the frightened and helpless", and certainly he cites enough cases to demonstrate the existence of both. But there is clearly more to be said, as when he remarks that "many of the [health-food] magazines are owned by the same organisations that make and sell the health foods". This is indeed "more than interesting" because through such magazines manufacturers can freely make claims that even the feeble British regulations would forbid them to publish in advertisements. The implication that the followers of the health food movement are encouraged in their views by a gospel of arrant nonsense, surreptitiously funded by manufacturers, is a worrying one. Here is a can of wholemeal worms that should have been opened wider.

Though manipulation of information may in part be the reason for the rapid growth of the health food industry (turnover has increased by 400% in Britain in the past decade, for example), it is not enough to account fully for its success. Bender briefly mentions other factors, such as the general hypochondriasis about food in our society, and the pervasive Western wish to believe in a Golden Age of dietetic innocence, when, guided by nature, we unerringly chose the diet of untarnished pastoral perfection. It is, I think, a pity that he did not examine more fully the reasons why we are so prone to these obsessions, and particularly the role that his (and my) profession has played in encouraging everyone to believe that eating should carry a government health warning.

This is part of a general weakness in the book. In pointing out the error of the health fooders' ways at such length, Professor Bender necessarily asserts continually that the nutritionist knows best. This may be true more often than not, but sometimes he is unduly soft on scientists and complacent about what they have shown or done. When he states that artificial sweeteners are safe because tests have not shown them to be harmful in human beings, or that "apart from premature babies, extra Vitamin E does not have any value", there is a real danger of confusing particularly the lay reader not only about the nature of scientific proof but about the extent of a professional consensus on these issues. On the other side of the coin he sometimes quotes relatively weak scientific evidence as demonstrating a *proven* danger of health food products, as, for example, in his listing of toxic effects of high doses of Vitamins C, B_6 and B_1, where the professional view (as evidenced by the other two books discussed here) would be that there is no firm evidence as to the adverse effects of overdoses of these compounds. And while he pronounces long and loud about even putative cases of vitamin poisoning attributable to the advocacy of health food freaks, he says nothing about the crop of deaths of children in Britain 30 years ago which resulted from professional nutritionists advocating too high a level of supplementation of infant foods with Vitamin D: a compound that, as he says, is more poisonous than cyanide.

These remarks are not intended as a defence of the health food business or to detract from Professor Bender's well-justified attack on it. It is just that I regret what I see as unnecessary certainty in his tone because it lessens the force of his criticisms. It is particularly unfortunate in a book which ends with a chapter giving advice on a healthy diet. For what Professor Bender recommends is the currently fashionable recipe of low fat, low saturated fat, less sugar, less salt and more fibre. The sort of advice, in short, which not so long ago nutritionists were wont to ridicule when health food cranks proposed it.

Such errors are inevitable in a science whose discoveries can be implemented so easily, and which has a public avid to hear of each whisper of a miracle. But that makes it necessary for its practitioners to consider carefully everything they say, particularly when writing for the general public. To some Professor John Yudkin would seem an arch-offender against this precept, an eloquent voice who has put his views on the adverse effects of dietary sucrose to the public over the heads of his colleagues. In fact Yudkin has devoted very little of his working life to attacking sucrose. Far more of it was spent in devising the first undergraduate degree in nutrition, a pioneering attempt to provide in a single course a perspective on the diverse disciplines — from cooking to physiology, economic history to chemistry — of which a nutritionist should be aware. In doing that he also fostered neglected areas of the subject, most notably the social and historical, that have suffered because many scientists (and, in Britain, the Research Councils) see nutrition simply as applied biochemistry.

The Penguin Encyclopaedia of Nutrition is a reflection of this side of Yudkin's activities. It is a large book, but neither exhaustive nor exhausting, and an amalgam of some truly nutritional entries and some plucked from the ancillary disciplines that Yudkin has always argued a would-be nutritionist must master. The entry on health foods jostles one on *p*H, gout is discussed, so is osmotic pressure, nutrient balance and locust beans. Necessarily much is missed out and it seems that Yudkin has frequently chosen to concentrate upon what interests him. There is a long entry

on sucrose, of course, but much more on the history of nutrition, notably the succinct biographies of many of the founders of nutritional science and the accounts of the food habits and nutritional impact of the Neolithic revolution. The air of relaxed authority emerges in entries such as that on "Food", which he calls "a word universally used and presumably universally understood" but not susceptible of a "sufficient and necessary definition" before going on gently to refute the slick definitions found in dictionaries. This a reference work to browse through and ruminate upon. It will be particularly useful to those who feel impelled to pronounce upon nutritional matters, among whom one might include the authors of the third book reviewed here.

Diet-Related Diseases, a collaborative effort by an epidemiologist, an immunologist, a chemist and a clinical psychologist, is a refreshing book but suffers from three things. The first is the unevenness in style, predictable in a multiple-author volume. The second is the cover: a clichéd photograph of a collection of junk foods that fails to reflect the thrust of the book and suggests that the publishers did not fully appreciate what their authors have tried to do. For in no sense is this book clichéd, nor is it particularly concerned to attack or defend junk food. What the authors do is set out what they see as possible roles for diet in many of the diseases of the affluent society, and to present both conventional and novel (and in parts highly idiosyncratic) analyses of this case. The core is a collection of chapters by Stephen Seely which set out the evidence for a dietary role in arterial diseases and various cancers; on the periphery are chapters by his colleagues on food toxicants, food allergies, diet in mental illness, and diet and ageing.

Seely is the author of a provocative series of papers in *Medical Hypotheses* which have tried to cast new light on the well-trodden field of diet and degenerative diseases chiefly by attempting a more thorough analysis of data on national diets and the prevalence data on diseases. While the evidence is set down in the book with commendable clarity, it is the very clarity which makes apparent the occasional, but important, misconception about the quality of the nutritional, and other, assumptions which underpin the arguments.

Here lies the book's third and most serious fault. For example, Seely's analyses make great use of estimates of per capita availability of foodstuffs in various countries, which he calls "food consumption data". They are not: the two may differ by some hundreds of calories and the discrepancy is a notorious source of error. He asserts axiomatically that "a correlation coefficient of 0.9 denotes a degree of positive correlation when causal connection is probable". He suggests that the longevity of the human species is explained by our low level of energy consumption for our size. This is an arguable contention, but it is presented in a way that suggests Seely is unaware of Rubner's work of a century ago which showed that human beings live four times longer than a comparative study of energy turnover would suggest, or of Flourens's (1856) "law of longevity" that lifespan of different species is about five times as long as the duration of the growth period, a generalization that does fit the human species.

Such errors might yield to a more thorough training in nutrition and a respect for its historical background such as is to be found in Yudkin's *Encyclopaedia*. But though Seely's theories would be better for greater nutritional sophistication, this failing does not destroy the book. What particularly recommends itself is not the correctness or otherwise of the authors' specific views, it is an overall air of caution, reasonableness and balance in their tone. Even when the writers are expounding their own pet theories they sound more like judges than prosecutors. I hope they produce more books, because dispassionate commentators will be in demand as nutrition increasingly becomes a public health issue which is seen to require missionary zeal on all sides. □

John Rivers is a Senior Lecturer in the Department of Human Nutrition at the London School of Hygiene and Tropical Medicine, University of London.

Biology at work

Norman Carey

Biotechnology and Genetic Engineering Reviews, Vols 1 and 2.
Executive editor Gordon E. Russell.
Intercept, PO Box 2, Ponteland, Newcastle upon Tyne/Scholium, 265 Great Neck Road, Great Neck, New York: 1983/1984. Each volume pp. 450, £50, $79.50.

AT THE moment that these volumes arrived on my desk for review I was in conversation with one of my colleagues. "Oh no", he said, "not another one. There's too much being written about biotechnology these days." I suppose the comment could mean either that the topics have already been well covered elsewhere or that the speaker does not have time to read all that appears on the subject. Whether this series really is "too much" depends on the objectives and whether they are achieved.

The term "biotechnology" was coined at the time of the revolution in thinking which was brought about by the arrival of recombinant DNA techniques. To many people it has come to mean the industrial application of recombinant DNA. Indeed, it does to some of the authors of articles in these volumes, as is evidenced by the use of the word (Vol. 1, p.231). Of course, although a new (or at least newly publicized) term, by any definition biotechnology covers a multitude of highly profitable industrial activities which long pre-date the recombinant revolution.

In his preface, the editor refers to this fact. He says that the articles are intended to cover biotechnology "in the widest sense of that word". He implies, however, as does the title of the books, that it is the application of recombinant DNA which is the unifying feature of the articles. If that were the intention, then I feel there would be some value in a series such as this. One is forced to conclude, however, that this cannot be the aim, since many of the contributions scarcely mention *in vitro* recombination. The first article in Vol. 1, for example, "Applications of Biocatalysts to Biotechnology" (a few years ago this would have been called "Industrial Applications of Enzymes"), mentions genetics and protein engineering once, in the penultimate paragraph of the conclusions.

Perhaps, then, I have read too much into the title and preface. Maybe the series is intended to be a set of reviews on biotechnology and the title just has a high buzz-word quotient. In that case, the volumes should be judged by the quality of the articles and need for a review of each field. While there are a number of similar review series without a recombinant slant, this kind of duplication has not been a disadvantage in any other field.

Most of the contributions are informative and well written. However, there is an unnecessary degree of superficiality and repetition which a firm editorial hand should have dealt with. For example, three of the articles in Vol. 2 contain accounts of how to do cDNA and genomic cloning which are at once too slight to be of value to anyone who wishes to learn the techniques and too familiar to anyone with a degree in biochemistry. Such descriptions are now in the textbooks and do not belong in a series of "up to the minute in-depth reviews", to quote the preface again.

Librarians in industrial laboratories may subscribe to this series. But I think it likely that they will consider that scientists in their companies already know more about the topics in their own fields than these articles contain, and that they would have no reason to refer to such a wide variety of other subjects. However, libraries serving university departments of biochemistry and microbiology should have it. As general reading, most of the articles would be valuable to advanced and even first degree students; moreover, they do provide an excellent picture of the breadth of application of their disciplines. This series shows biotechnology both as high-quality science and as an important and valuable industrial activity. □

Norman Carey is Director of Research and Development at Celltech Ltd, Slough, Berkshire.

ANNOUNCE

Biodata Handling with Microcomputers

by A B Barlow

Student's 't' test, Mann Whitney 'U' test, Wilcoxon signed rank test, 4-point assay with confidence limits, Spearman rank correlation coefficient, linear regression, Hansch analysis, enzyme kinetics by direct fit, radioimmunoassay, radioligand binding assay and much, much more

A manual giving the mathematical background to dozens of analytical methods in the biosciences, showing how they are transformed into (fully listed) BASIC programs, illustrated by worked examples

Chapters include. Operating a computer; Some statistical programs; Line-fitting by least squares; Some applications to chemical ideas eg binding of drugs to receptors, Running other machines

'. The combination of disk and book certainly add up to a useful elementary statistical package ' *Nature*

Manual vi + 261 pages (spiral bound) ISBN 0 444 80539 7
Disk 5¼" floppy disks (Apple II [3 3 DOS], Apple IIe – each 3 disks Commodore PET [40 or 80 col display, SD or DD, please specify] – 1 or 2 disks Commodore 64 (also available for Vic 20) – 2 disks IBM personal computer – 2 disks BBC Microcomputer [40 or 80 track] – 2 or 3 disks.

Mathematics, Biology and Microcomputers by A N Barrett

This book/disk package is aimed at both practitioners and students with an interest in methods for the analysis of biological data, modelling of biological processes and the determination of molecular properties

The book provides both text and program listings, with detailed documentation and examples, written in BASIC for the Apple II, IBM PC, and BBC microcomputers The programs can easily be transferred to other computers which also run BASIC The disk contains all the programs listed in the book.

Chapters cover (*I*) Definitions and explanations of the BASIC statements used in the programs, (*II*) Methods for solving non-linear equations and evaluations of polynomials, and sets of simultaneous linear equations Matrix computations including formation products and inversion Evaluation of determinants and solutions to sets of equations using Cramer's rule (*III*) Determination of molecular properties including computation of bond distances, angles and direction cosines, fitting of lines and planes to specified coordinates Coordinate systems and transformations Methods for rotation of structures about specified axes including graphics display of results and graphics representation of conic sections. Differential geometry and properties of helical structures (*IV*) Fitting of nonlinear curves to data including the parabola, hyperbola and exponential functions Numerical methods of integration which include the Trapezium, Simpson's and Three-eighths rule. Calculations of volumes Statistical methods covering computation of means and standard deviations and evaluation of statistical distributions Numerical approach to the manipulation of sequence data using prime numbers

Manual vi + 102 pages (spiral bound)
Disk 5¼" floppy disk (Apple II [3 3 DOS], [BBC 40 or 80 track], IBM PC)

Statstream by A Bangham

STATSTREAM has at its heart a library of 76 procedures including data entry, graphing, text-windowing, statistical tests, function-fitting etc These can be used very simply by.

(1) Calling the helpful menu-driven Statpack, which enables a variety of parametric and non-parametric tests to be done, after a single data entry

(2) Using the 24 demonstration programs designed to teach the user all about statistics and fitting functions to data.

(3) Writing straightforward BASIC programs to incorporate the desired procedures

STATSTREAM is usable by, and useful for, everyone from the beginner, new to statistics and computing, to the professional statistician or research worker who wishes to incorporate the elegant STATSTREAM procedures in his own BASIC programs It is also a first class educational tool

STATSTREAM comprises two packed 5 25" floppy disks for the Apple II series (which can be used with one or two drives) (3 3 DOS, min 48K RAM)plus a comprehensive manual

Expert 4 by R. Rivers

An easy-to-use sophisticated disk-based 'Expert System' for the IBM PC at an incredibly low cost.

EXPERT4 can be used to create and manipulate a knowledge base, which employs models of human reasoning or 'artifical intelligence' It draws on deductive and fuzzy logic, multidimensional statistics and cognitive psychology The theory behind EXPERT4 is fully discussed in the documentation which accompanies the disk.

EXPERT4 offers a spreadsheet which enables the user to create files or 'domains' each of which is made up of 'elements' which have 'attributes'. These have 'attribute values'. For example, in a domain called 'People', 'Jane' is an element One of her attributes is 'Hair colour' Jane has brown hair hence 'Brown' is the attribute value

Inferencing facilities in EXPERT4 calculate and display relationships amongst the elements and attributes in terms of similarity and typicality. Any two selected items can be compared in detail for their similarity and differences An example use would be to assist with diagnosis of a group of diseases with similar symptoms

Other potential uses of EXPERT4 are manifold, but to give the user an introduction to the program, two completed domains are incorporated on disk as examples

Package includes.
Documentation + 5¼" floppy disk for the IBM PC

TO ORDER

Barlow: BIODATA HANDLING WITH MICROCOMPUTERS
(i) Manual (Please specify Basic or Applesoft) *US $30; UK £18*
(ii) Disks (please specify machine for which disks are required – see above) *US $50; UK £30*

Barrett: MATHEMATICS, BIOLOGY AND MICROCOMPUTERS
Manual + disk (please specify Apple II, BBC [40 or 80 track] or IBM) *US $36; UK £24*

Bangham: STATSTREAM
Manual + disk for Apple II *US $99; UK £66*

Rivers: EXPERT4
Documentation + disk for IBM PC *US $99; UK £66*

GENE MANIPULATION IN FUNGI

J.W. Bennett and L.L. Lasure

1985, c.552pp., In Preparation, ISBN. 0.12.088640.5

This book is the first on *molecular mycology*, a new hybrid discipline. The authors have emphasized the juxtaposition of several fields of inquiry which have been separated from one another by tradition, training, and organism.

Meant to be a lasting reference that reviews existing data and provides the state-of-the-art for new molecular biology, this book will be of interest to plant pathologists, medical mycologists and others whose disciplines deal with fungi.

SPECIAL PUBLICATIONS OF THE SOCIETY FOR GENERAL MICROBIOLOGY, Number 14

MICROBIAL GAS METABOLISM:

Mechanistic, Metabolic and Biotechnological Aspects

Edited by Robert K. Poole and Crawford S. Dow

1985, 278pp., $55.00/£44.00 (UK only), ISBN: 0.12 561480.2

This book discusses the biochemical basis of gas generation and utilisation by microorganisms. Exciting developments and new details of metabolic pathways and biochemical mechanisms are elucidated, emphasising, where appropriate, the commercial and biotechnological potential of such processes An introductory chapter dealing with the bioinorganic chemistry involved is provided at the beginning of the volume. Subsequent chapters are grouped into sections which cover the gases, oxygen, hydrogen, carbon monoxide, methane, nitrogen and its oxides, and the measurement of these gases by mass spectrometry.

MONOCLONAL ANTIBODIES AGAINST BACTERIA

Edited by J.L. Macario and E. Conway de Macario

Volume I

1985, 336pp., $45.00/£45.00 (UK only), ISBN: 0.12.463001.4

This treatise is aimed at assembling seminal contribution in the field of bacterial immunology centred on monoclonal antibodies The contributors are pioneers, and the contributions themselves are, for the most part, first attempts at reviewing data and publication in their particular restricted areas. One of the main purposes of the book is to provide in a single reference work as much fundamental data as possible on generation, characterization, and utilization of monoclonal antibodies against bacteria, and other monoclonal products (e.g., lymphokines) relevant to antibacterial immune responses. As such, this treatise should be regarded as a milestone, a place where some of those who were the first to generate and to work with monclonal antibodies against bacteria paused for a while and reviewed their original observations.

Volume II

Late 1985, In Preparation, ISBN. 0 12.463002.2

SOCIETY FOR APPLIED BACTERIOLOGY TECHNICAL SERIES, Number 19

MICROBIOLOGICAL METHODS FOR ENVIRONMENTAL BIOTECHNOLOGY

Edited by J.M. Grainger and J.M. Lynch

1984, 440pp., $65.00/£45.00 (UK only), ISBN· 0.12 295040.2

This book describes the use of a wide variety of modern microbiological techniques in environmental protection and waste management. Environmental biotechnology is considered in a broad context, extending beyond sewage treatment to aspects pertinent to agriculture, food, and other manufacturing industries, and to the exploitation of renewable resources of energy and materials

CELL CULTURE AND SOMATIC CELL GENETICS OF PLANTS

Edited by I.K. Vasil

Volume I: Laboratory Procedures and Their Applications

1985, 284pp., $85.00/£68.00 (UK only), ISBN: 0.12.715001.3

"The first volume of this series from Academic Press deals with laboratory procedures in cell culture and somatic cell genetics of plants .... The contributors present helpful 'how-to-do-it' instructions with a good selection of important references. A wide range of practical methods is covered in 85 short, easily read chapters and little difficulty should be experienced in following most of the methods given."

Nature

Volume II: Cell Growth, Nutrition, Cytodifferentiation and Cytopreservation

Late 1985, c.284pp , In Preparation, ISBN: 0.12.715002.1

THE BACTERIA

Volume VIII: A Treatise on Structure and Function

Edited by C.R. Woese and R.S. Wolfe

1985, 608pp, $85.00/£85.00 (UK only), ISBN: 0.12.307208.5

Contents: *Biochemical Diversity and Ecology of Archaebacteria:* **W.B. Whitman,** *Methanogenic Bacteria* **K.O. Stetter and W. Zillig.** *Thermoplasma and the Thermophilic Sulfur-Metabolizing Archaebacteria.* **D.J. Kushner,** *The Halobacteriaceae.* **J. Hahn an P. Haug,** *Sedimentary Record and Archaebacteria Translation Apparatus of Archaebacteria:* **G.E. Fox,** *The Structure and Evolution of Archaebacterial Ribosomal RNA.* **R. Gupta,** *Transfer Ribonucleic Acids of Archaebacteria.* **A.T. Matheson,** *Ribosomes of Archaebacteria.* **F. Klink,** *Elongation Factors. General Molecular Characteristics of Archaebacteria:* **O. Kandler and H. Konig,** *Cell Envelopes of Archaebacteria.* **T.A. Langworthy,** *Lipids of Archaebacteria.* **W. Zillig, K.O. Stetter, R. Schnabel, and M. Thomm,** *DNA-Dependent RNA Polymerases of the Archaebacteria.* **A. Böck and O. Kandler,** *Antibiotic Sensitivity of Archaebacteria.* **W.F. Doolittle,** *Genome Structure in Archaebacteria.* **C.R. Woese and R.S. Wolfe.** *Epilogue Archaebacteria: The Urkingdom Each chapter includes references. Index.*

A FEMS Symposia Publication

MICROBIAL DEGRADATION OF XENOBIOTICS AND REACALCITRANT COMPOUNDS

Edited by T. Leisinger, A.M. Cook, R. Hütter and J. Nüesch

1981, 400pp , $69 50/£48.00 (UK only), ISBN. 0.12 442920.3

Contents: Section Headings *Part One.* **The Scope of the Problem.** *Part Two:* **Enrichment for and Genetics of Degrading Microbes.** *Part Three:* **Catabolism of Aromatics.** *Part Four.* **Pesticides.** *Part Five·* **Lignin, Detergents and Dyes.**

MITOCHONDRIA IN HIGHER PLANTS:

Structure, Function, and Biogenesis

R. Douce

1985, 322pp., In Preparation, ISBN: 0.12 221280 0

This book is intended not only for research workers and students interested in the enzymology of plant mitochondria respiration but also for graduate and undergraduate students in the field of plant biochemistry, cell physiology, and molecular biology. The book may be useful as a starting point for those students wishing to pursue special studies in this field.

OVERPRODUCTION OF MICROBIAL PRODUCTS

Edited by V. Krumphanzel, B. Sikyta and Z. Vaněk

1982, 725pp., $75.00/£52.00 (UK only), ISBN: 0.12.426920.6

Contents: Section Headings *Part I* **Physiological Manipulations.** *Part II* **Genetic Manipulations.** *Part III* **Biological Aspects of Technological Manipulations.**

A FEMS Symposia Publication

FUNDAMENTAL AND APPLIED ASPECTS OF BACTERIAL SPORES

Edited by G.J. Dring, D.J. Ellar and G.W. Gould

1985, In Preparation, ISBN: 0.12.222080.3

Based on a joint FEMS-SAB meeting this volume comprises an impressive and up to date assembly of current spore related research. Contributions cover fundamental advances in the study of genetics, sporulation, resistance and the germination of spore formers. Particular consideration is given to applied research in the food and pharmaceutical industries, agriculture and medicine.

The First Volume in the AMERICAN SOCIETY OF PLANT PHYSIOLOGISTS MONOGRAPHS Series

PLANT PEROXISOMES

A.H.C. Huang, R.N. Trelease, and T.S. Moore, Jr.

1985, 252pp., $34.50/£28.00 (UK only), ISBN: 0.12.358260.1

This unique volume is a lucid and thorough illustration of the significance of plant peroxisomes and their roles in plant physiology and metabolism. It describes and explains the various types of cytochemical tests used to define the function and distribution of these organelles in plant cells and reviews the biochemical and metabolic aspects of fungal and algal peroxisomes. Also included are a description of glyoxysomes in oil seeds, fungi, and algae; current information on the biogenesis of plant peroxisomes; and a comprehensive discussion of the historical perspective on peroxisomal studies. The authors also discuss current research on fatty acid β-oxidation in animal peroxisomes and the synthesis, intracellular transport, and packaging of peroxisomal proteins in both plants and animals. The book will be of interest to plant biochemists and physiologists, botanists, cell biologists and horticulturists.

BIOACTIVE MICROBIAL PRODUCTS 1

Search and Discovery

Edited by J.D. Bu'Lock, L.J. Nisbet and D.J. Winstanley

1982, 148pp., $29.00/£19.50 (UK only), ISBN: 0.12.140750.0

Contents: *Introduction: Needs, Ways, and Obstacles to Discovery,* **J.D. Bu'Lock.** *Principles and Problems of Selective Isolation of Microbes,* **S.T. Williams and E.M.H. Wellington.** *Culture Preservation and Instability,* **A. Dietz.** *Design of Culture Media Capable of Provoking Wide Gene Expression,* **R. Hütter.** *Novel Approaches to Metabolite Screening,* **H. Zahner, H. Drautz and W. Weber.** *Screens for Pharmacologically Active Fermentation Products,* **R.L. GENETICS AND BIOTECHNOLOGY OF BACILLI

Edited by A.T. Ganesan and J.A. Hoch

1985, 416pp., $41.50/£33.50 (UK only), ISBN: 0.12.274160.9

This book is a collection of recent advances and research information in the field of Bacillus genetics and biotechnology. The results, obtained since a 1981 international conference by leading scientists, are presented on topics such as genetics, cloning strategies, plasmid vectors, phages, spores, and sporulation products.

The interest in this field shown by participants from universities and leading biotechnology firms indicates that Bacilli may well emerge as the organisms of choice for genetic engineering. The collection will serve as an invaluable source for all biotechnology firms, university libraries, and microbiology, genetics, and biology departments.

ANIMAL CELL BIOTECHNOLOGY

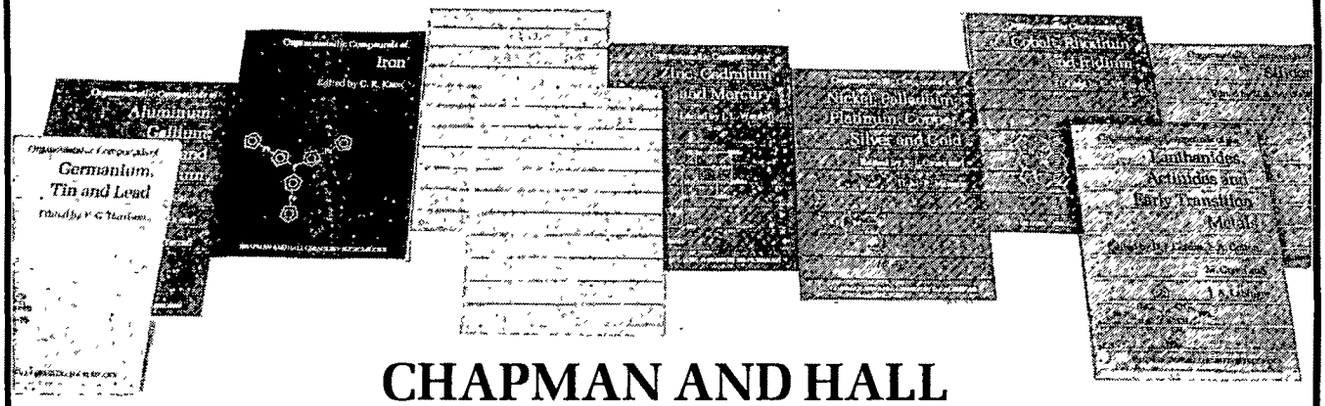
Edited by R.E. Spier and J.B. Griffiths

Volume 1

1985, 344pp., In Preparation, ISBN. 0.12.657551.7

Volume 2

1985, 502pp., In Preparation, ISBN: 0.12.657552.5



Animal Cell Biotechnology is directed towards two groups of people. Those entering the field for the first time will find many details about how to set up and operate cell cultures in a variety of ways and at scales ranging between 0.001 and 10,000 litres. Others who are already engaged in the area will find that the comprehensive coverage of the selected topics written by experts in the various subjects will provide them with a well referenced and indexed state-of-the-art report.

ATTENTION! ALL ORGANOMETALLIC CHEMISTS

CHAPMAN AND HALL

Chemistry Sourcebooks

Bench-top reference volumes specifically tailored to the everyday requirements of individual researchers.

Derived from the Dictionary of Organometallic Compounds, these ten Sourcebooks provide easy access to the key data on the most important and most useful organometallic compounds.

Each Sourcebook contains compounds divided according to metal element: thus allowing individual researchers to carry the data relevant to their own specialization within just one or two volumes.

Every Sourcebook has:-

- ☐ clear and concise dictionary format
- ☐ comprehensive and complete indexing
- ☐ an additional structure index
- ☐ data on over 1000 organometallic compounds
- ☐ information derived from the acclaimed DOMC
- ☐ attractive bench/desk top presentation
- ☐ excellent value – you need only buy the information of direct reference to your research interests

Each of the sourcebooks is of similar structure:-
Preface; Introduction; Structure index; Entries in molecular formula order; Molecular formula index; CAS registry number index.

The Sourcebooks are paperbacks 276 × 210 mm in size, published in May 1985.

For a FREE full colour brochure, please write to:-

Building for the scientist

Michael Brawne

Design, Construction and Refurbishment of Laboratories.
Edited by R. Lees and A. F. Smith.
Ellis Horwood/Halsted: 1984. Pp.375. £37.50, $79.95.

LABORATORIES are among the most expensive and least permanent of buildings. Any attempt to increase awareness of the difficulties in designing them must be welcomed, and must be seen as a contribution towards more satisfactory solution of an especially intractable building problem. Economics, of course, are often a decisive factor and it is at the same time especially important to keep the apparently high capital cost in perspective: as W.P. Horswell, one of the contributors to this volume, points out, the capital cost of a science department at a British university, calculated as an annual mortgage payment, is only 14 per cent of the running cost — 86 per cent goes to recurrent costs — and is only 7 per cent if buildings and land alone are counted. This, however, is a relationship that rarely influences the decisions of universities and other institutions funding laboratory buildings.

It was the aim of the editors, two scientists at the Laboratory of the Government Chemist in London, that the work of the 40 contributors should build up into a kind of mosaic to cover a wide range of issues and enable the designer of a new or a refurbished laboratory to avoid the major pitfalls. The foreword, moreover, suggests that the information should be widely relevant in both developed and developing countries.

As might be expected, the 36 chapters which make up the book differ both in intention and quality. Many of them contain useful information, clearly set out; some deal with generalities, without in the short space available going beyond these; and a few do no more than to set out checklists, which may be helpful reminders to those who already know the answers but do little to transmit any knowledge. Few say anything original, but there are some surprises. For example, in his paper on safety, N.H. Pearce of Bristol University suggests that the accepted wisdom on fire escapes, enshrined in legislation and enforced by fire officers, may actually make conditions much worse by trapping smoke rather than allowing it to disperse.

Nor is there necessarily unanimity among the contributors. As in science itself there will always be different views of what is most appropriate in a laboratory building. Not only are the final decisions invariably the upshot of a set of value judgements made by the designer, but laboratories are continually changing to reflect advances in scientific and technological research and to house the new equipment best suited to that research. Developments of the recent past have resulted in a drift towards opposite ends of the scale; towards very large equipment, as in radioastronomy or nuclear research institutions such as CERN, or towards miniaturization. A common factor, however, is that many controlling, measuring and recording instruments are in some way dependent upon computer technology, yet little of that impact is described in the book. At an elementary level, for example, the use of visual display units has serious implications for lighting but no mention of this is made in the pertinent chapter.

A number of the issues covered — on flexibility and adaptability, on safety, on the choice between conversion of an old building or construction of a new one, on reliability principles or building appraisal in use — have clear application to other building types and are thus of general interest. Some of the more particular discussions also have relevance beyond laboratory design since a number of other types of building — for the manufacture of electronic components or the processing of food — may well need much the same conditions. Thus, for all its failings, the book should have appeal beyond those principally concerned with laboratories.

It should never be forgotten that a laboratory is not only a place of work but is a kind of home for a large number of people. In the conversations I have had with scientists in both the physical and the life sciences for whom I have designed laboratories, the final and most searching questions were always about "what will it be like to be there?". It is assumed that there will be enough fume cupboards or adequate electrical screening; what is difficult to pin down and capture is that elusive sense of place. The book says nothing about this. Perhaps the editors felt that it was unimportant or outside their mandate; so, unfortunately, have too many others who have been responsible for laboratory buildings. □

Michael Brawne is Professor of Architecture at the University of Bath.

Ways to deal with discrete data

P.W. Hawkes

Digital Image Processing Techniques.
Edited by Michael P. Ekstrom.
Academic: 1984. Pp.372. $49.50, £40.
Applications of Walsh and Related Functions: With an Introduction to Sequency Theory.
By K.G. Beauchamp.
Academic: 1985. Pp.308. $55, £33.50.

MANY books have now been published on image processing, ranging from full-scale treatises to multi-author texts on certain specialized topics. Ekstrom's volume repeats much material already presented in more detail elsewhere, but it aims to meet a need not yet specifically catered for: how can an outsider know which of the many branches of image processing he ought to study in depth to solve his particular problem, and what hardware and software is already available? This is indeed a problem, for the introductory volumes are thick and the advanced ones incomprehensible to the uninitiated.

Ekstrom has invited a distinguished team to contribute short accounts of most of the main themes of image processing, from which the reader can rapidly grasp what the methods are capable of doing and whether they might be of use to him. The chapters cover enhancement, restoration, detection and estimation, 3-D reconstruction, coding, spectral estimation and analysis, and a longer concluding contribution surveys architecture, display hardware, software and the various systems. This should therefore be regarded as a guidebook rather than a textbook, and as such it is extremely successful.

Image processing is the subject of one of the chapters in Beauchamp's new book on discrete functions, which conveniently brings together much scattered material, but which, owing no doubt to this diversity, is very uneven. The opening chapters on the functions and transforms themselves are clear and full, including many interesting details about such important questions as the problem of shift-variance and the conversion from one transform to another.

The second half of the book, in which applications as various as seismology, medical signal processing, image enhancement and restoration, non-sinusoidal electromagnetic radiation and minimization of logic functions are discussed in 120 pages, is much less satisfactory. In some cases the text provides a good introduction to the more detailed literature, but in others the treatment is so inadequate that omission of the topic would have been the better course. Section 6.3.3 on image restoration occupies barely one page, for example, and, still in Section 6.3, it is not much use to be told that "optical .. images [are] always positive quantities and therefore do not obey completely normal statistical operations". Conversely, the four pages on nonlinear applications of signal processing do succeed in conveying the originality of Walsh functions. This, then, is a useful book, but one which could have been much better. □

P.W. Hawkes is Maître de Recherches at the Laboratoire d'Optique Electronique du CNRS, Toulouse.

The Amphibian Ear

Ernest Glen Wever

This comprehensive work on the amphibian ear continues the examination of the nature and evolutionary development of the vertebrate ear begun in Ernest Glen Wever's earlier book, *The Reptile Ear* Professor Wever studies the structure of the ear and its functioning as a receptor of sounds in all amphibian species (139) for which living representatives could be obtained Structure is revealed by gross dissection methods and the microscopic examination of serial sections, functioning is shown by general behavioral observations, particularly by the recording of electrical potentials produced by the auditory hair cells in response to sounds $65 00

Vision as a guide to action

Stuart Sutherland

Visual Perception: Physiology, Psychology and Ecology.
By Vicki Bruce and Patrick Green.
Lawrence Erlbaum: 1985. Pp.369. Hbk £26.95, $39.95; pbk £8.95, $14.95.

IN THE edifice of visual psychology are many mansions. Most textbooks on the subject describe only the more conventional ones — colour vision, the visual illusions, visual after-effects, flicker, perspective, adaptation to wearing prisms and so on. In *Visual Perception* Vicki Bruce and Patrick Green ignore these hoary topics and present instead some of the exciting new developments that have taken place over the past 20 years. Their book is unusual: it provides almost the first elementary account of the use of computer simulation to further our understanding of vision (rightly relying mainly on the work of David Marr); it devotes many pages to vision in insects; and rather than concentrating on how visual sensations are produced or visual recognition achieved, it examines in some detail how vision can guide action.

For good measure, the authors throw in a useful and up-to-date account of the neurophysiology of the visual system including a description of X, Y and W cells, of whose elusive properties nobody has yet succeeded in making sense. They write and argue clearly, and, as a supplement to existing textbooks or as an introduction to an advanced course on vision, the book will be invaluable; it could also be helpful to workers in other scientific disciplines who want to learn about recent developments in vision.

There are, however, a few faults, some of which arise because topics are not dealt with in sufficient breadth. For example, in describing how lines and edges are extracted from the image to achieve Marr's "primal sketch", Bruce and Green should have attempted to motivate the reader by giving the reasons why this is, rather surprisingly, a very difficult thing to do; or again, they describe Marr and Nishihara's method of representing objects for the purpose of recognition without attempting to evaluate carefully how far it fits in with our current knowledge of the visual system; and their account of scene analysis is so condensed that the uninformed reader will have difficulty understanding what it is all about. Moreover, several of their diagrams are completely wrong (for example those on pages 76, 131 and 264) and will puzzle or mislead the unsophisticated.

A more debatable feature is the attention paid to the ideas of J.J. Gibson, who believed that the dynamic visual image contained invariants that specified what was present in the environment, and that these invariants were "picked up" directly by the eye with no underlying computational or inferential processes. The view is so silly that it is not worth taking seriously. Gibson was of course correct in believing that the starting point for what we see is the visual image, but who has ever doubted that? One example of an invariant is horizontal disparity between corresponding parts of the image on the left and the right eye: this disparity yields stereoscopic depth. But when we examine how disparity is actually detected and used, it turns out to be extremely complicated; despite much computational work on stereopsis over the past few years, there is still no theory that is completely adequate.

The same is true of most other invariants. Nor does one have to have read Gibson to understand that the time at which an object approaching at a constant speed will collide with someone's head can be derived from the expression dt/ds, where s is the angle subtended at the eye by any two points on the object, and t is the time of observation. As the authors point out, a more elaborate expression yields the hit-time for an object that is accelerating at a constant rate. Both the insect and the human brain almost certainly make use of formulae like these, the former for landing, the latter, among other things, for driving across busy intersections without collision. The use that organisms make of such invariants is fascinating and is spelt out in detail in the present book, but the formulations owe little or nothing to Gibson's ideas (which, after wasting much space on them, the authors are in any case eventually led to reject).

This misplaced emphasis on Gibson apart, Bruce and Green have written an interesting and pleasingly idiosyncratic book. If you want to know why sheep dogs can be trained to round up sheep, you will find the answer here, just as you will find answers to many other rarely discussed questions. And it is salutary to have a textbook that stresses that vision is a guide to action and not merely a device for providing a picture of the world in one's head. □

Stuart Sutherland is Director of the Centre for Research on Perception and Cognition at the University of Sussex.

Review Editor:
C. R. Lowe, *University of Cambridge, The Biotechnology Center, Downingstreet, Cambridge CB2 3EF U.K.*

Aims and Scope

The journal provides a medium for the rapid publication of full-length articles as well as short communications on various aspects of biotechnology. Information on new or potential applications of biotechnological relevance in the following areas will be considered for publication:

- molecular biology
- genetics
- biochemical aspects of metabolism and its control, including viral, microbial, plant and animal cell systems
- process development and its control, including computer applications automation and the development of (bio)-sensors as applied to biosystems.

The overriding criteria for publication are originality, high scientific quality and interest to a multidisciplinary audience.

BIOTECHNOLOGY BULLETIN

To make the most of the opportunities offered by biotechnology – one of the world's most rapidly emerging technologies – it is essential that you keep up to date with the latest developments.

BIOTECHNOLOGY BULLETIN, launched in 1982, has established itself as a concise and authoritative, up-to-the-minute source of facts and figures for biotechnologists, investors and public sector agencies – whether involved in researching, promoting or regulating biotechnology.

Published monthly, its coverage includes information on industrial biotechnology processes; details of the latest Government policies and investment programmes; advance information on R & D projects; company briefs; review of the emerging projects and explanations of the new scientific advances; key patent developments, and a diary of courses, conferences and events.

Since May 1985, **BIOTECHNOLOGY BULLETIN** has expanded to include an extra two pages a month which will be used to report on a particular organisation or current area of interest to subscribers.

Annual subscription rate £110.

BIO-JAPAN

The Emerging Japanese Challenge in Biotechnology

by John Elkington

Watch out for Japan in commercial biotechnology. Companies that have not considered Japan as a serious competitor in this lucrative market should take heed of this message, for, as John Elkington's new report shows, there is every chance that by the end of the 80's Japan will have emerged as a serious rival to established market leaders in the U.S. and Europe.

The acquisition of new skills and technologies from abroad, coupled with increasing collaboration and joint ventures, has enabled Japan to reinforce its weaker areas and build on its undoubted strengths. Significant progress is now being made in such areas as genetic engineering; bioprocessing and separation technology; pharmaceuticals and other health products; and the applications of biotechnology in such diverse fields as biomass energy, metal recovery and pollution control.

Providing up-to-the-minute analysis of the current and prospective state of the Japanese biotechnology market, this report will be a vital tool for industrialists, whether they regard the Japanese challenge as a threat or as an important commercial opportunity.

FORTHCOMING EVENTS

- DNA PROBES AND MONOCLONALS – RECENT ADVANCES IN THEIR DEVELOPMENT AND APPLICATION
  23rd/24th September 1985, London
- HUMAN LYMPHOKINES – THERAPEUTIC AND MARKET PROSPECTS
  9th October 1985, London
- SECOND EUROPEAN SYMPOSIUM ON COMPUTER-AIDED MOLECULAR DESIGN
  17th/18th October 1985, Basel, Switzerland
- FIRST INTERNATIONAL CONFERENCE ON PROTEIN ENGINEERING
  21st/22nd November 1985, London

To receive a full programme of any of these events, please complete the order form below.

ORDER FORM

HPTLC pre-coated plates NH_2 F_{254} S

A medium-polar layer with weak basic ion exchanger properties

Separation of carboxylic acids*):
HPTLC pre-coated plates NH_2 F_{254} S (15647)
1 Pyromellitic acid
2 Benzene-1,2,3-tricarboxylic acid
3 Benzene-1,2,4-tricarboxylic acid
4 Phthalic acid
5 Benzoic acid
} 10 mg of each in 10 ml

Applied volume: 300 nl
Eluent: 0.18 mol/l NaCl in ethanol/ammonia solution (60/40)
Migration distance: 5 cm
Normal chamber without chamber saturation UV 254 nm, CAMAG TLC/HPTLC scanner

*) W. Jost, H. E. Hauck, J. Chromatography 261, 235-244 (1983)

These pre-coated plates are, inter alia, particularly suitable for separating:

Carboxylic acids
Nucleotides
Phenols
Purines
Pyrimidines
Sulfonic acids

Please ask for our brochure.

at Nature's fourth international conference, to be held at the Novotel London, June 25th-27th, 1985

NEW TECHNOLOGY in BIOTECHNOLOGY

In the past five years, even the enthusiasts of the new biotechnology industry have often been surprised at the speed with which new opportunities have emerged. The initial focus was on the use of *Escherichia coli* for manufacturing polypeptides and proteins.

NOW...

- other bacteria as well as yeasts are also being used and attention is turning to mammalian and plant cell systems.
- improvements to the polypeptides and proteins produced are being achieved by deliberate mutagenesis of the genes introduced into the cells.
- new strains of plants and animals are being established from engineered embryonic cells.
- the manipulation and production of monoclonal antibodies and enzymes are becoming ever more refined and the goal of representing a large protein by a much simpler peptide is within reach.
- progress is being made in coupling biotechnology to electronics, so producing sophisticated measuring devices.

As in the past, these developments spring from basic research at academic and, increasingly, at industrial laboratories.

THE OBJECTIVE of this *Nature* conference (the second to be held in Britain) is to provide a survey of the recent research that will influence the evolution of biotechnology in the next few years.

THE SPEAKERS have been chosen for the originality of their own contributions to these topics, but they will also provide a survey of recent work related to their own immediate interests.

THE FORMAT of the conference will provide ample opportunity for discussion—each formal presentation will be followed by a question period, and there will also be appropriate round-table discussions.

PARTICIPANTS in the conference will be provided in advance with a selection of reading matter intended to provide background to particular talks.

DON'T MISS THIS OPPORTUNITY

to catch up with New Technology in Biotechnology

CONFERENCE PROGRAMME

Day 1 Tuesday, June 25th

MORNING

Enzymes, immunogens
Dr D. Thomas, Université de Technologie de Compiègne.
Dr. G Winter, MRC Laboratory of Molecular Biology, Cambridge.
Dr. A. Klug, MRC Laboratory of Molecular Biology, Cambridge.

AFTERNOON

Antibodies
Dr. J Birch, Celltech Ltd., Slough.
Dr. M. Neuberger, MRC Laboratory of Molecular Biology, Cambridge.
ROUND TABLE DISCUSSION

Day 2 Wednesday, June 26th

Biosensors
Dr M. Flanagan, University College, London
Professor I.J. Higgins/Dr. A. Turner, Cranfield/Leicester:
Micro-organisms
Dr. S. Emtage, Celltech Ltd., Slough.

Micro-organisms continued
Professor D. Hopwood, John Innes Institute, Norwich.
Dr. B. Carter, Searle R&D, High Wycombe
ROUND TABLE DISCUSSION

Day 3 Thursday, June 27th

Mammalian systems
Professor P. Tiollais, Institut Pasteur, Paris.
Dr. A. Levinson, Genentech, San Francisco.
Dr. R. L. Brinster, University of Pennsylvania

Plants
Professor M. Fowler, Wolfson Institute, Sheffield.
Professor J. Schell, Max Planck Institut, Köln
ROUND TABLE DISCUSSION or FINAL TALK

POSTER SESSIONS will be held each day and will be open to those registering for the conference Please send a title and a brief synopsis to Dr Peter Newmark, Deputy Editor, Nature, 4 Little Essex Street, London WC2R 3LF, UK

SPACE IS LIMITED REGISTER NOW!

TO REGISTER, return the form below with your cheque or authorised purchase order from your organisation TODAY! Applications are accepted only on completion of a booking form We ask you to complete *one form per person* We cannot guarantee to accept applications received after June 3rd, 1985

THE FEE is just £170 plus VAT for the duration of the conference or £74 plus VAT per day This includes entrance to all sessions, mid-morning coffee, afternoon tea and advance reading material Applications without payment will be acknowledged but will not be *confirmed* until payment is received In cases where a participant is being sponsored by an organisation, the organisation will be invoiced and once payment has reached us the participant will be sent confirmation of his or her place

THE SETTING is London's NOVOTEL, situated conveniently within easy reach of the City's most famous sights and also the West End which boasts some of the world's best shopping and entertainment It is also close to the main road into London from Heathrow Airport

ACCOMMODATION has been reserved in the NOVOTEL and elsewhere for conference participants A booking form will be sent to you as soon as we receive your registration

THE CONFERENCE DINNER will be held on Wednesday, June 26th This is always a popular event and SPACE IS LIMITED so make your reservation on the form below today The cost will be £15 65 plus VAT

AN INTERNATIONAL EXHIBITION will be held in conjunction with the conference

NOTE: Cancellations received before May 27th, 1985 will be refunded less a processing charge No refunds can be made after this date

CONFERENCE, please return this form with your payment to: DEBORAH JONES, Conference Administrator, Macmillan Conferences & Exhibitions, 4 Little Essex Street, London WC2R 3LF, U.K.

BIOTEC 85 DÜSSELDORF

NEW TECHNOLOGY IN DÜSSELDORF.
October 15 to 17, 85

BIOTEC – International Conference and Exhibition for Bio and Gene Technology – will be presenting a concentration of innovations along with the current status of enzyme technology, and microbial genetic engineering

Well known scientists from USA, Japan and Europe will be attending Major companies from R & D and industry will be presenting their work in a Lobby Show

BIOTEC will prove of strong interest to food technologists, plant growers, pharmaceutists, biochemists and enzymologists The event will also attract young scientists

For further information please contact Dusseldorfer Messegesellschaft mbH – NOWEA – P O Box 32 02 03, D 4 Düsseldorf 30, W-Germany Telephone 2 11/45 60 1, Telex 8,584 853 mes d

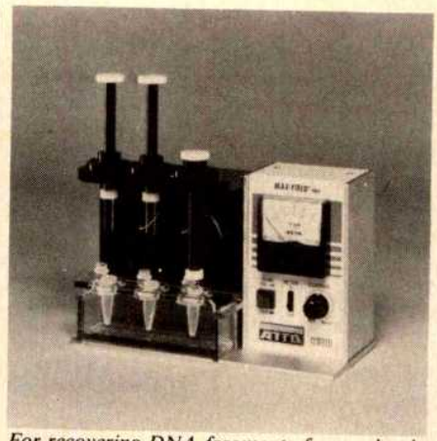
Reader Service No.02

Putting the technology into biology

Recent entrants onto the expanding 'biotechnology market' include sophisticated computerized systems for monitoring fermentations.



● A new all-glass bioreactor from Astra Scientific has been designed specifically for cell culture applications. Working volume is 10 litres (20 litres total), and the vessel has a hemispherical bottom and is dimensioned to provide the optimum 1:1 height to depth ratio required in this application. The vessel is completely jacketed up to its maximum working volume capacity for accurate temperature control. Two impellers provide gentle agitation, and accurate speed is assured through the use of a tachometer and feedback control loop.
Reader Service No. 100.

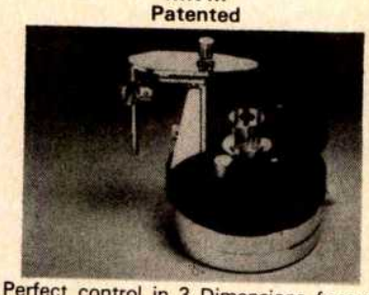
SGI's all-glass bioreactor is marketed by Astra Scientific in the United States.

● Monoclonal antibody scale-up is among the services offered to the biotechnologist by Celltech. Celltech specializes in bulk antibody production having the facilities to produce monoclonals in kilogram quantities. Celltech is also active in the business information field — Abstracts in BioCommerce is a commercial news index available as an on-line computer database.
Reader Service No. 101.

● The new Dako catalogue for 1985 permits easy location of any one of over 400 antisera, purified proteins and immunohistochemical staining kits — including monoclonal and polyclonal antibodies. Recent additions include a new line of fluorescein- and peroxidase-conjugated $F(ab')_2$ fragments of antibodies. A FITC-conjugated $F(ab')_2$ rabbit antibody against mouse immunoglobulins is useful in screening for immunoglobulin production in hybridoma cultures.
Reader Service No. 102.

For recovering DNA fragments from gels, the DNA-3 Max-Yield.

● The DNA-3 Max-Yield system, now available from Genetic Research Instrumentation, has been designed specifically to recover DNA fragments from electrophoresis gels quickly with high yields and no further nicking of the fragments. Up to 98% of each band fragment may be recovered and the system may be used as a purification procedure or for DNA recovery for further experimental assays. The DNA-3 will process up to three samples simultaneously and is complete with its own power supply, tube rack and microelectrodes. Gel fragments are placed within a special holder which in turn is placed within a 1.5 ml microcentrifuge tube. Between 200 and 500 μl of buffer is added to each tube and ice is added to the tube rack in which the tubes are resting. A pair of microelectrodes is lowered into each tube, one either side of the gel fragment, and voltage is applied. At a voltage setting of 20 volts, DNA will be removed from the fragments within 15 to 20 minutes.
Reader Service No. 103.



● A four-page bulletin describing Pall Biodyne ImmunoAffinity Membrane, a solid support for immobilization of antibodies and antigens, with particular application for use in immunodiagnostic test procedures, is available from the Biotechnology Division of Pall Ultrafine Filtration Corporation. Suggested protocols are provided for immobilization and binding of monoclonal or polyclonal antibodies and antigens to the membrane by wetting, immersion or perfusion. Protocols for the blocking of nonspecific protein binding to Biodyne ImmunoAffinity membranes are also discussed. The membrane is available in precut disks, squares, cartridges and roll form. It is offered in two standard pore sizes: 0.1 and 0.2 μm, but other pore sizes can be ordered.
Reader Service No. 104.

● Bacteriophage T7 gene 6 exonuclease, a 5′-3′ exonuclease with a strong preference for double-stranded DNA, is now available from United States Biochemical Corporation. Its catalytic mechanism allows it to be used for controlled digestion of DNA in both analytical and preparative experiments. The exonuclease is available in packages of 2,000 or 10,000 units; each unit is enough enzyme to release 1 nmol of acid-soluble nucleotide in 15 min at 37°C.
Reader Service No. 105.

● Cross-reactivity with both human and mouse immunoglobulins has been virtually eliminated in Tago's expanded line of goat antibodies to rat IgG (H and L chains). Tago conjugated anti-rat IgG products are designed for use as a second antibody with rat monoclonal IgG in indirect immunoassays and histochemical staining. They are especially suitable for ELISA and flow cytometry. The range includes conjugates with fluorescein, lissamine rhodamine, horseradish peroxidase, alkaline phosphatase, β-galactosidase, or biotin.
Reader Service No. 106.

ADVERTISEMENTS

SINGER MICROMANIPULATER MK III
Patented

Perfect control in 3 Dimensions from a single joystick. Continuous variable reductions to suit all magnifications. No after sales maintenance needed.

The LH Fermentation 2-litre airlift fermenter.

● A new 2-litre airlift fermenter that will be ideal for monoclonal antibody production, media optimization and other similar applications is available from LH Fermentation. Based on a 2-litre total volume glass vessel, the fermenter has a working volume of 1,700ml with a removable glass draught tube and a stainless-steel top plate. This has ports for oxygen and carbon dioxide electrodes and other sensors. Temperature control is via thermostatically controlled water circulated around a jacket on the glass vessel; agitation is achieved on the standard unit by the "air-lift" principle with a glass sinter providing the gas dispersion. Also from LH Fermentation is a new microprocessor-based fermentation control package which can monitor eight parameters in single or multiple fermentation.
Reader Service No. 107.

● Four new restriction enzymes have been added to Boehringer Mannheim's line of premium enzymes — *Asp*700, *Ban*I, *Dde*I, and *Nco*I. *Asp*700 is an isoschizomer of *Xmn*I. Another recent introduction from Boehringer is a ribonuclease inhibitor prepared to high quality for molecular biology. The preparation is supplied with a volume activity of 10–50 units per μl. It is checked for the absence of endonucleases and nicking activity.
Reader Service No. 108.

● Promega Biotec's Protoclone GT system allows the cloning and expression of a DNA insert in one day. Protoclone GT is a lambda gtll cloning and expression system which is particularly useful in the construction of cDNA libraries. It achieves high cloning efficiencies and a high percentage of insert-containing clones. And for RNA probe synthesis, Promega Biotec has introduced Riboprobe Gemini, a system allowing selective synthesis of RNA from either DNA strand following a single plasmid construction. Riboprobe Gemini produces useful plasmids for probe synthesis regardless of the insert orientation. The kit consists of: (1) two specially prepared RNA polymerases, bacteriophage SP6 polymerase and T7 polymerase; (2) two plasmids, each containing SP6 and T7 promoters flanking a multiple cloning site; (3) positive control transcription template.
Reader Service No. 109.

North, south or west, Turbo Blot makes blotting simpler.

● The American Bionuclear Turbo Blot filter processing system is the first device of its kind to handle the set-up and washing of Southern, Northern and Western blots. Hybridization and antibody binding reactions are quickly and safely performed, without need of a heat sealer, via a disposable pouch system. Probe reagents are conveniently added and removed from the pouch by means of a syringe. Blots are washed in minutes in a vacuum-wash system providing backgrounds typically lower than with manual processing.
Reader Service No. 110.

● New Plant Products, the first trading activity of Agricultural Genetics Company, has published a new leaflet describing their range of rhizobium inoculants for legumes. NPP produces a high quality product based on sedge peat containing strains of rhizobia specially selected for their nitrogen fixing ability from the extensive collection of rhizobia held at Rothamsted Experimental Station. The basic range covers all the legume crops grown in Europe and NPP can also supply inoculants for use in the tropics, and for the more unusual legumes used for reclamation work. Agricultural Genetics Company was set up to make use of the fruits of the Agricultural and Food Research Council's plant biotechnology research programme.
Reader Service No. 111.

● New from Systec Inc. is 1/2 μm phosphoramidite synthesis software for the Microsyn-1450A automated DNA synthesizer. The Microsyn-1450A syringe delivery system permits the addition of just 7.8 mg of phosphoramidite base per synthesis cycle. The quantity of CPG support is also halved in this new synthesis program (approximately 20 mg per synthesis). The 1/2 μm software does not compromise either coupling reaction efficiency (98.5–99.5%) or cycle time (6.25–7.5 minutes). It is available for use with either *O*-methyl di-isopropyl or β-cyanoethyl di-isopropyl phosphoramidites.
Reader Service No. 112.

● Dianorm's Liposomat achieves the reproducible preparation of uniformly sized unilamellar liposomes (formed within just 10 minutes) with very high encapsulation efficiency for both hydrophilic and lipophilic agents. The liposome size is selectable between 25 and 600 nm diameter, with a lipid loss of less than 1%. Sample volume is normally 5-10 ml but can be up to 200 ml if the Liposomat is used with other apparatus. The Liposomat is especially suitable for studying drug/protein/cell—liposome interactions *in vitro* and *in vivo*, for reconstitution experiments, and for the transfer of genetic material in gene- and biotechnology.

Monoclonals in cartoon form.

● A layman's explanation of monoclonal antibodies is now available on videocassette from Hybritech Europe. The video, entitled "The Monoclonal Antibody Revolution", presents in cartoon form (1) The fundamental principles of the immune reaction; (2) how antibodies can be used for medical purposes; (3) the difficulties encountered with "polyclonal antibodies"; (4) the breakthrough represented by monoclonal antibodies; (5) immediate medical applications; (6) near-term future potential.
Reader Service No. 114.

● Two new monoclonal antibody purification systems (MAPS) utilizing affinity chromatography and hydroxylapatite (HPHT) have been introduced by Bio-Rad. Affi-Gel protein A MAPS makes use of a column matrix of protein A crosslinked to agarose beads. When used with specially optimized MAPS binding, elution and regeneration buffers, Affi-Gel protein A has a binding capacity for mouse IgG_1 from ascites fluid that it is 8-10 times higher than that attainable by published methods. Affi-Gel protein A is also ideal for purifying human immunoglobulins, with a binding capacity of 20 mg of purified IgG per ml of gel. HPHT-MAPS can be used in a dedicated hydroxylapatite HPLC system for separating monoclonal antibodies from usual contaminants, such as albumin and transferrin, as well as other contaminating immunoglobulins. Using the HPHT-MAPS system, mouse monoclonal antibodies can be ultra-purified regardless of class or sub-class.
Reader Service No. 115.

● Several new hybridization probe DNAs have been added to the Oncor range. These highly purified, sequence specific DNA fragments are designed for use in nick-translation reactions and for the detection of oncogenic sequences by nucleic acid hybridization. The new probes include DNAs to detect the following sequences: *abl*, *Alu*, *erb-1*, *fes*, *sis* and *src*. Also available are antibodies to *src* and epidermal growth factor receptors. The probes are supplied in a kit containing control DNAs. Technical data sheets are available on request from the UK distributors, Stratech Scientific Ltd in London (tel. 01 354 2601).
Reader Service No. 116.

Four individually-controlled shakers make up the Bioengineering Associates environmental control cabinet.

● Bioengineering Associates Inc. has introduced an environmental control cabinet containing four individually controlled shaking units. The flow of air guarantees uniform distribution of temperature, gaseous mixtures and humidity. Shaker heights are adjustable, allowing different shakers to be run with various size flasks; as well as a variety of speeds between 10 and 400 r.p.m. The temperature range is approximately 15°C below room temperature to 80°C with ± 0.2°C accuracy. Magnetic drive ensures silent vibration-free running, without the need to anchor the four units.
Reader Service No. 117.

● Seraclone fetal calf serum is specially selected for its ability to support the growth of mouse hybridoma and/or myeloma cells in limiting dilution cloning in microtitre plates at 1 cell per well. Only those fetal calf sera which support cloning efficiencies of ± 100% as predicted by Poisson distribution frequencies are given the label Seraclone. Available from Sera-Lab of Crawley Down in Sussex, this new grade of fetal calf serum is suitable for all phases of monoclonal antibody production.
Reader Service No. 118.

● The latest edition of the Serotec catalogue of monoclonal and polyclonal reagents has many new additions including sheep anti-human antisera to complement proteins, thyroid hormones, coagulation factors, serum proteases and inhibitors, conjugated to FITC, TRITC, peroxidase and alkaline phosphatase; purified monoclonal antibodies to immunoglobulins, serum components, MHC antigens and leukocytes; and mouse and rat monoclonal antibodies to MHC antigens and immunoglobulins. Serotec has established a network of distributors in Australia, Denmark, Greece, Ireland, Italy, Israel, Japan, New Zealand, Portugal, Spain, Sweden, Switzerland, Taiwan, The Netherlands, West Germany, Korea and Canada and is in final negotiations with companies in the United States.
Reader Service No. 119.

● Clontech now has cDNA libraries available for researchers. These libraries are prepared from human, rat and mouse tissues, from various cell lines, and there is also a yeast genomic library. The vectors are lambda gt10, gt11 and pBR322.
Reader Service No. 120.

● MicroGenie from Beckman Instruments is a software program which can collect, analyse and compare nucleic acid and protein sequences. MicroGenie can be used by the computer novice, guided with simple menus. It can analyse sequences of up to 60,000 nucleotides, enough for bacteriophage lambda or adenovirus. The memory stores up to a million nucleotides.

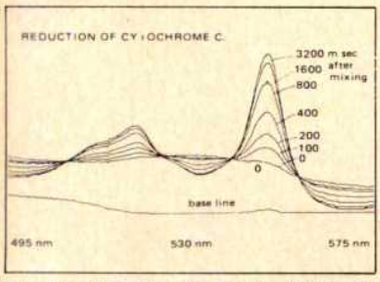
UNION GIKEN

First choice for

STOPPED FLOW



reaction analysis

Union Giken apparatus achieves a dead time as short as ½ millisecond for measurement of fast reactions. Gas pressure is directly applied to the surface of the reactants in each reservoir, mixing and flow being controlled from the end of the system by a high-response stop valve. The RA-401 STOPPED FLOW SPECTROMETER is the ideal match for fast reactions.

The RA-451 DATA PROCESSOR generates a simulated reaction curve from the measured results and automatically calculates the rate constant.

The RA-415 RAPID SCAN ATTACHMENT monitors the change in absorption spectrum during the reaction.

Other attachments are available for T-jump, P-jump, fluorescence and flash photolysis.

Computer-directed DNA synthesis — Autogen 5500.

● Genetic Design of Watertown Massachusetts has developed the AutoGen 6500, the first automated DNA synthesizer to incorporate computer-directed variable-cycle control of the synthesizing process. The new system has the capacity for automatic synthesis of as many as three sequential 100-base fragments with no operator intervention. The AutoGen 6500 uses an Apple IIe computer (128KB, dual disks, CRT, voice synthesizer, Okidata 92 printer) for all control functions. Software is user-programmable by simple menu-driven commands. In addition, numerous utilities are provided for cycle and function parameterization defined by the user. A modem and printer are included with each system.
Reader Service No. 122.

● Now available in the UK from P & S Biochemicals of Liverpool, Promega Biotec's Packagene system is a single-extract *in vitro* lambda DNA packaging system. By combining all the necessary components and buffers in one tube, the system enables the user to conduct a packaging reaction simply by adding a sample of DNA to a volume of Packagene and incubating. Packaging efficiencies of over 10^8 PFU per μg DNA are guaranteed, allowing effective and successful construction of DNA libraries.
Reader Service No. 123.

A new medium for hybridomas.

● Ventrex Laboratories have formulated a new serum-free cell culture medium, HL-1, that is ideal for hybridomas and lymphoid cells. HL-1 will facilitate the *in vitro* scale-up of monoclonal antibody production and simplifies or eliminates purification steps. In the United Kingdom, HL-1 is available from Tissue Culture Services of Slough.
Reader Service No. 124.

● A powerful new data acquisition and logging package has been introduced by the Laboratory Computer Systems Division of Milequip, the Gloucestershire based computer systems house. The package, known as Logger, is ideal for use with medium- or long-term biotechnological and process biochemical experiments and by technicians with no previous computer experience. The program runs in real time with a variable scanning interval. Following each scan, readings are displayed with an average facility for data reduction of a large number of scans, if required. Readings outside of preselected parameters sound an audible alarm, which may be deactivated if required.
Reader Service No. 125.

● The LSI mammalian cell transfection kit has been developed to make the transfer of stably expressing genes into mammalian cells a simple routine operation. Each kit includes: (1) All the pre-tested solutions for calcium phosphate transfecting up to 100 100-mm plates of cells; (2) a detailed protocol; (3) sterile 0.2-μm syringe filters; (4) sterile storage vials; (5) test results for each lot. This new LSI kit is available from Vanguard International of Neptune, New Jersey.
Reader Service No. 126.

● Mentor is a new computer process control and data logging system for fermentation, developed by Life Science Laboratories Ltd of Luton. The software is optimized so that the Mentor system can be installed on an existing as well as a new fermentation plant without delay. Mentor 1 hardware is IBM PC based and utilizes a colour VDU, floppy disk drive, Winchester disk and six-pen colour plotter. The system is completely menu-driven with all aspects of configuration and operation being available to the keyboard user through a high-level language. Control sequences for operation of valves and loops can be specified by the user such that routines like sterilization, inoculation and transfers can be carried out automatically.
Reader Service No. 127.

● Bethesda Research Laboratories' new murine reverse transcriptase, Cloned M-MLV RT, synthesizes a higher percentage of full-length cDNA from mRNA than does avian reverse transcriptase. Murine RT is free of many of the contaminants common in avian RT preparations. BRL has cloned the reverse transcriptase coding sequence from M-MLV (Moloney murine leukaemia virus), ensuring reproducibly high performance. Full-length cDNAs can be synthesized more efficiently using Cloned M-MLV RT because it does not contain the DNA endonuclease activity associated with AMV RT. Purity is greater than 95% and there is no detectable DNase or RNase.
Reader Service No. 128.

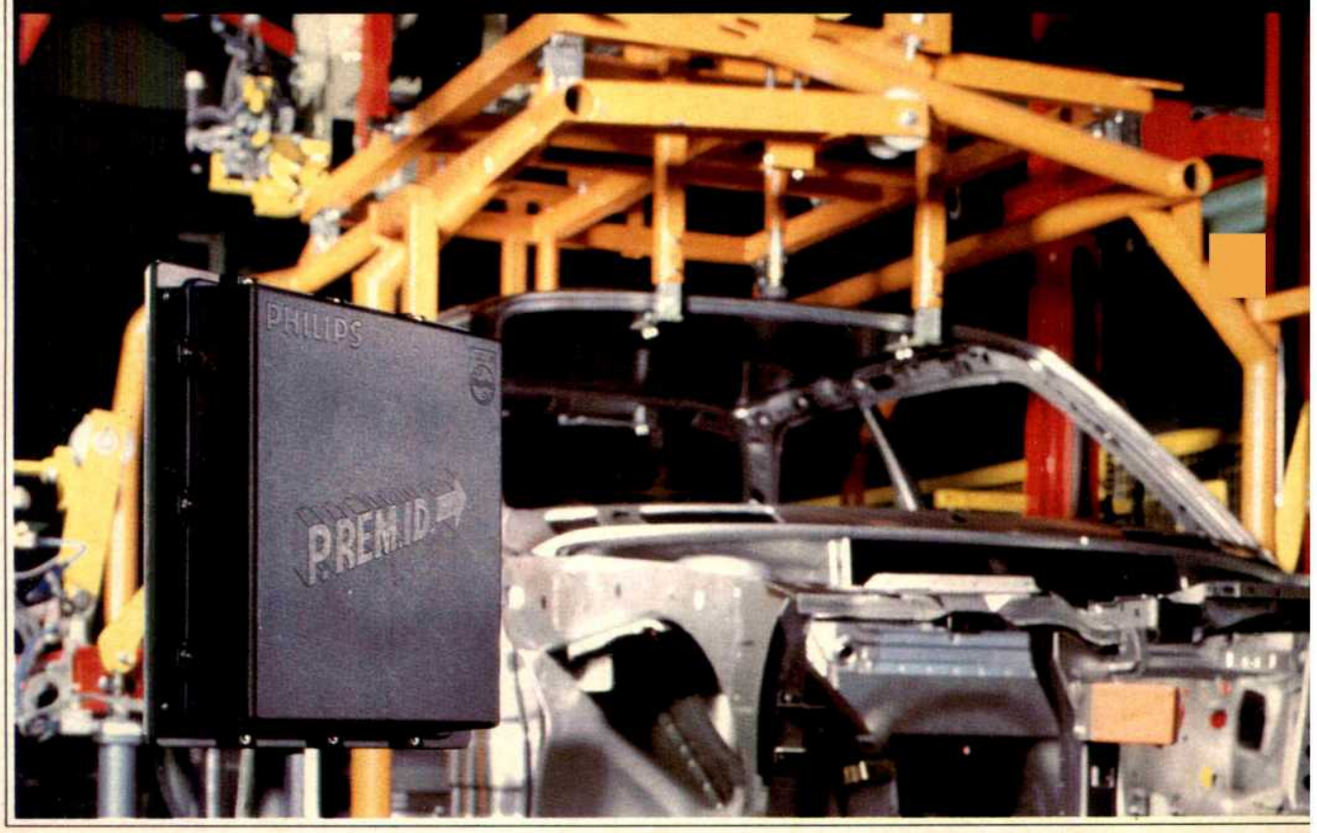
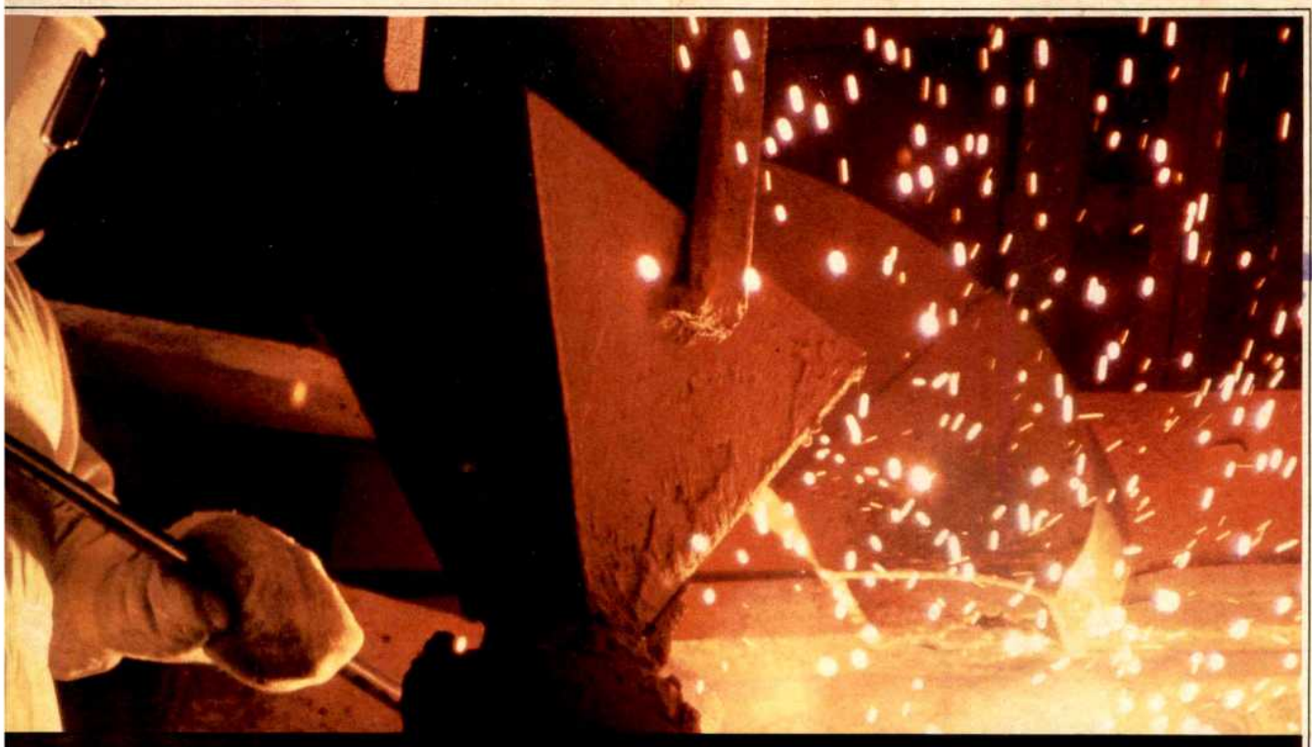
MEDIUM-ENERGY HEAVY IONS



Wuhan's Number 2 Steel Works, in the Peoples' Republic of China, has recently made use of Philips expertise in industrial automation to improve its efficiency, quality and use of raw materials.



The Philips electronic weighing and batching system, which now forms the sophisticated heart of the factory, controls three LD converters, each equipped with six weighing hoppers for additives, two for intermediate bunkers, and one for ladle additive. Individual compact batching systems are connected to a supervisory micro-computer controller.

In addition, electronic weighing techniques are employed at various other stages of the process. For example, when scrap is charged into the converter, it is weighed on a specially designed platform with built-in protective features to prevent damage.

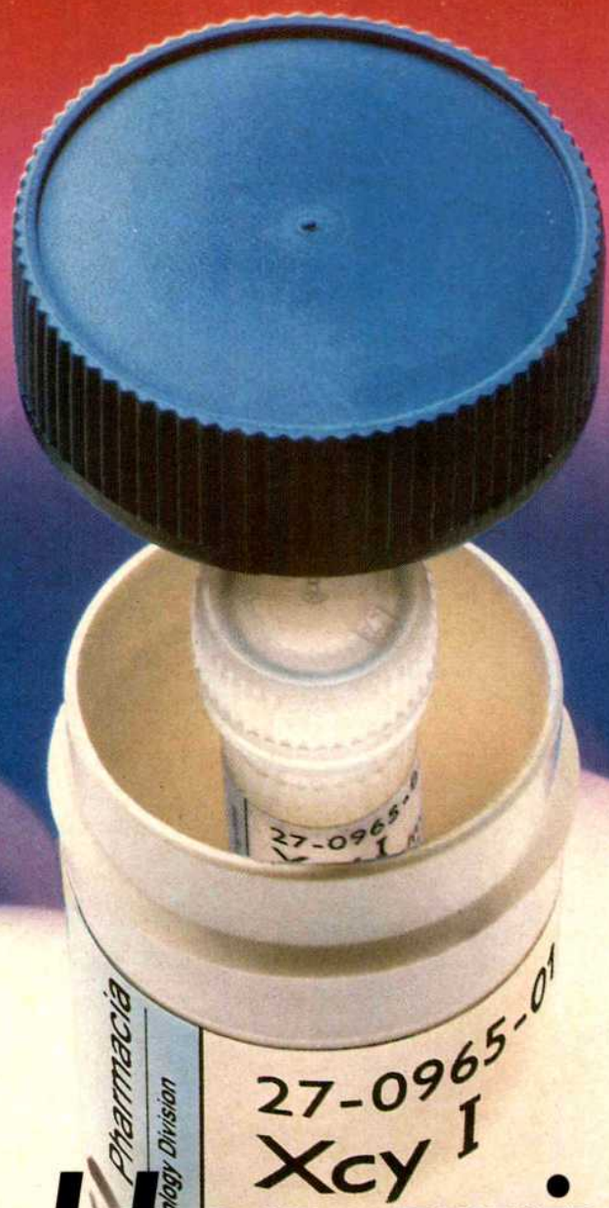
In Germany the problem was how to ensure that production ran smoothly, while still offering customers "made-to-measure" cars.

We help fight metal fa
customised BMW

ue in China, and build n Germany.

The Philips P.REM.ID. system (Programmable REMote IDentification) has been introduced with great success for the production of BMWs. The system includes "recognition" modules, which are programmed through a microwave signal. These signals determine which particular item is required for which individual car.

In this way, a personalised car – with a special gear box, transmission system, interior, and so on – can be included in the normal assembly line. The system allows a high degree of flexibility, while retaining a high output level on the line.



These are but two examples of how Philips expertise can be put at the service of industry – throughout the world. For more information about Philips expertise world-wide, write to the Philips organization in your country or to Philips C.P.M.S., VOA-0217/N9, Eindhoven, the Netherlands.

Philips. The sure sign of expertise world-wide.

PHILIPS

Hot on delivery...

...cold on arrival

When you order molecular biologicals from Pharmacia you'll find we're pretty hot on delivery.

We'll dispatch your order as soon as we get it, packing it carefully in wet or dry ice.

Now our enzymes are supplied in screw cap mini vials with new waterproof labels, and will easily fit into your centrifuge tubes and freezer trays.

At Pharmacia Molecular Biology Division that's all part of the service. We realize that the success of an experiment depends on the quality of the products used and the speed at which you get them. With us you'll find that the only thing kept on ice is your product – not your experiment.

Contact us today and we'll send you our free catalogue with details of over 800 molecular biologicals.

Pharmacia... your partner in molecular biology.

NATURE VOL. 315 23 MAY 1985

COVER

The French heavy-ion accelerator GANIL (Grand Accelerateur National d'Ions Lourds). GANIL consists of three cyclotrons, linked in series to produce some of the most complex of all nuclear phenomena. These occur when nuclei collide at energies too high for them to behave like drops of liquid yet too low to behave like clouds of independent neutrons and protons. GANIL physics is described by the director of the accelerator, Claude Détraz, on page 291.

DNA CHEMIPROBE ECONOMICAL NON-RADIOACTIVE LABELING SYSTEM FOR DNA

O.K. Adv. Israel

Principle of DNA CHEMIPROBE

A selected procedure for chemical modification of DNA, employing non-carcinogenic compounds, introduces unique antigenic sites. The modified DNA can be hybridized as usual and visualized by an enzyme immunoassay.

1 Simple modification procedure

Mix the denatured DNA sample (can be only partially purified) with ORGENICS sulfonation mixture and incubate 1-2 hrs. at room temperature.

Advantages: No nick translation, no manipulation of dangerous (e.g., carcinogenic) substances, no radioactivity, no need to purify DNA to completion.

2 Simple hybridization procedure

Just add the denatured modified probe to your hybridization mixture and follow your usual protocol or try Orgenics' suggested procedures.

Advantages: The DNA CHEMIPROBE and its reagents are stable. Proteins, such as enzymes, are not involved. Labeling your probe takes only a few minutes of actual work.

3 Simple visualization procedure

Use our highly specific monoclonal antibodies against modified DNA. These antibodies do not react with non-modified DNA. A second antibody conjugated to peroxidase or alkaline phosphatase is included in the kit for visualization.

Advantages: No handling of radioactivity. Long shelf life.

4 Suggested Applications

1. — Southern blotting

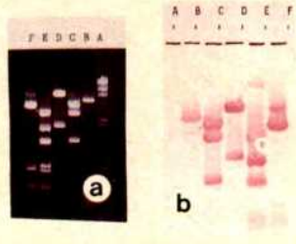

fig. 1

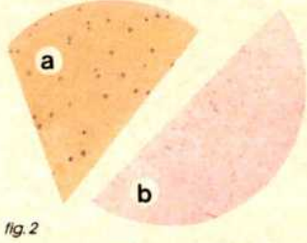
a) Restriction enzyme digest of pBR 328 and pSVK1 (plasmid containing pBR and SV-40 sequences)
b) Blot of restriction enzyme digest hybridized with pSVK1, modified by Orgenics CHEMIPROBE Kit. Detection by double sandwich enzyme immunoassay.

Lanes: A. λ /Hind III marker
B. pBR328/EcoR I
C. pSVK1/Pst I
D. pSVK1/EcoR I
E. pSVK1/Hind III
F. pSVK1/Stu I

2. — Dot hybridization



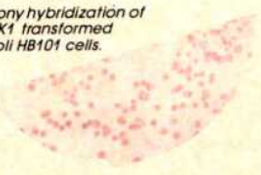


fig. 2

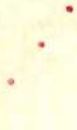
a) Plaques of M13mp8 and M13mp8 with pSVK1/Hind III insert.
b) Blot of plaques hybridized with pSVK1, modified by Orgenics CHEMIPROBE Kit. Detection by double sandwich enzyme immunoassay.

3. — Colony hybridization

fig. 3



Colony hybridization of pSVK1 transformed E. coli HB101 cells.

4. — Plaque hybridization

fig. 4

Dot hybridization to decreasing amounts of target DNA (pSVK1).

5 What about single copy gene?

Our system detects 5-10 pg of DNA under routine conditions by dot blot. Single copy genes? Let us know of your results ... as compared to other non-radioactive labeling systems.

6 Presentation:

A kit sufficient for modification of 1 mg of DNA and its visualization including:

— users' guide
— modification solutions(2)
— modified and non-modified DNA for control (2)
— blocking solution
— anti-modified DNA monoclonal Ab
— second enzyme conjugated anti immunoglobulin
— Chromogenic substrate cocktail

Introductory price: $80 FOB.

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an italic heading of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

JOIN US

at Nature's fourth international conference, to be held at the Novotel London, June 25th-27th, 1985

NEW TECHNOLOGY in BIOTECHNOLOGY

In the past five years, even the enthusiasts of the new biotechnology industry have often been surprised at the speed with which new opportunities have emerged. The initial focus was on the use of *Escherichia coli* for manufacturing polypeptides and proteins.

NOW...

- other bacteria as well as yeasts are also being used and attention is turning to mammalian and plant cell systems.
- improvements to the polypeptides and proteins produced are being achieved by deliberate mutagenesis of the genes introduced into the cells.
- new strains of plants and animals are being established from engineered embryonic cells.
- the manipulation and production of monoclonal antibodies and enzymes are becoming ever more refined and the goal of representing a large protein by a much simpler peptide is within reach.
- progress is being made in coupling biotechnology to electronics, so producing sophisticated measuring devices.

As in the past, these developments spring from basic research at academic and, increasingly, at industrial laboratories.

THE OBJECTIVE of this *Nature* conference (the second to be held in Britain) is to provide a survey of the recent research that will influence the evolution of biotechnology in the next few years.

THE SPEAKERS have been chosen for the originality of their own contributions to these topics, but they will also provide a survey of recent work related to their own immediate interests.

THE FORMAT of the conference will provide ample opportunity for discussion — each formal presentation will be followed by a question period, and there will also be appropriate round-table discussions.

PARTICIPANTS in the conference will be provided in advance with a selection of reading matter intended to provide background to particular talks.

DON'T MISS THIS OPPORTUNITY

to catch up with New Technology in Biotechnology

CONFERENCE PROGRAMME

Day 1 Tuesday, June 25th

MORNING

Enzymes, immunogens
Dr. D. Thomas, Université de Technologie de Compiègne.
Dr. G. Winter, MRC Laboratory of Molecular Biology, Cambridge.
Dr. A. Klug, MRC Laboratory of Molecular Biology, Cambridge.

AFTERNOON

Antibodies
Dr. J. Birch, Celltech Ltd., Slough.
Dr. M. Neuberger, MRC Laboratory of Molecular Biology, Cambridge.
ROUND TABLE DISCUSSION

Day 2 Wednesday, June 26th

Biosensors
Dr. M. Flanagan, University College, London
Professor I.J. Higgins/Dr. A. Turner, Cranfield/Leicester.

Micro-organisms
Dr. S. Emtage, Celltech Ltd., Slough.

Micro-organisms continued
Professor D. Hopwood, John Innes Institute, Norwich.
Dr. B. Carter, Searle R&D, High Wycombe.
ROUND TABLE DISCUSSION

Day 3 Thursday, June 27th

Mammalian systems
Professor P. Tiollais, Institut Pasteur, Paris.
Dr. A. Levinson, Genentech, San Francisco.
Dr. R. L. Brinster, University of Pennsylvania

Plants
Professor M. Fowler, Wolfson Institute, Sheffield.
Professor J. Schell, Max Planck Institut, Köln.
ROUND TABLE DISCUSSION or FINAL TALK

POSTER SESSIONS will be held each day and will be open to those registering for the conference. Please send a title and a brief synopsis to Dr Peter Newmark, Deputy Editor, Nature, 4 Little Essex Street, London WC2R 3LF, UK.

SPACE IS LIMITED REGISTER NOW!

TO REGISTER, return the form below with your cheque or authorised purchase order from your organisation TODAY! Applications are accepted only on completion of a booking form. We ask you to complete *one form per person.* We cannot guarantee to accept applications received after June 3rd, 1985.

THE FEE is just £170 plus VAT for the duration of the conference or £74 plus VAT per day. This includes entrance to all sessions, mid-morning coffee, afternoon tea and advance reading material. Applications without payment will be acknowledged but will not be *confirmed* until payment is received. In cases where a participant is being sponsored by an organisation, the organisation will be invoiced and once payment has reached us the participant will be sent confirmation of his or her place.

THE SETTING is London's NOVOTEL, situated conveniently within easy reach of the City's most famous sights and also the West End which boasts some of the world's best shopping and entertainment. It is also close to the main road into London from Heathrow Airport.

ACCOMMODATION has been reserved in the NOVOTEL and elsewhere for conference participants. A booking form will be sent to you as soon as we receive your registration.

THE CONFERENCE DINNER will be held on Wednesday, June 26th. This is always a popular event and SPACE IS LIMITED so make your reservation on the form below today. The cost will be £15.65 plus VAT.

AN INTERNATIONAL EXHIBITION will be held in conjunction with the conference.

NOTE: Cancellations received before May 27th, 1985 will be refunded less a processing charge. No refunds can be made after this date.

TO REGISTER FOR THE CONFERENCE, please return this form with your payment to: DEBORAH JONES, Conference Administrator, Macmillan Conferences & Exhibitions, 4 Little Essex Street, London WC2R 3LF, U.K.

An essential guide to successful production

This book provides concise and up-to-date information on vegetable crops grown in tropical regions. It contains details of all the factors affecting growth and a clear explanation of techniques that can be applied to increase the level of production. It will be of use to students, extension service staff and research workers who wish to enlarge their knowledge of the range of food crops available for growing in the tropics.
Vegetables in the Tropics provides full information on the cultivation and environmental requirements of about 140 crops.

Hardcover	ISBN *0 333 24266 1*	**£35.00**
Paperback	ISBN *0 333 24268 8*	**£15.00**

Reader Service No.97

Biotechnology is changing the world.

Hanover presents the latest international developments.

Within just a few years biotechnology has developed into a key technology which will undoubtedly become even more important in the future. Biotechnology already plays a major role in chemistry, pharmacology, nutrition and agriculture, as well as in the fields of energy and environmental protection. BIOTECHNICA '85 in Hanover will emphasize the importance of this revolutionary technology to future economic growth and development.

An international congress

28 internationally renowned authorities will deal with current problems, trends and developments (including scientific, practical and commercial aspects) in measurement, process control, the development of models and the application of computers, as well as biocatalysts, animal and plant cell cultures.

Symposia and workshops

Research institutes, universities and firms will be able to present their research findings, bio-technical products and processes at symposia, lectures and in workshop sessions. BIOTECHNICA '85 will thus serve as a forum for practical and industrial applications based on the latest research findings.

The congress and exhibition BIOTECHNICA will take place in conjunction with the Second US Symposium on Biotechnology, which is being sponsored by America's two major biotechnology associations.

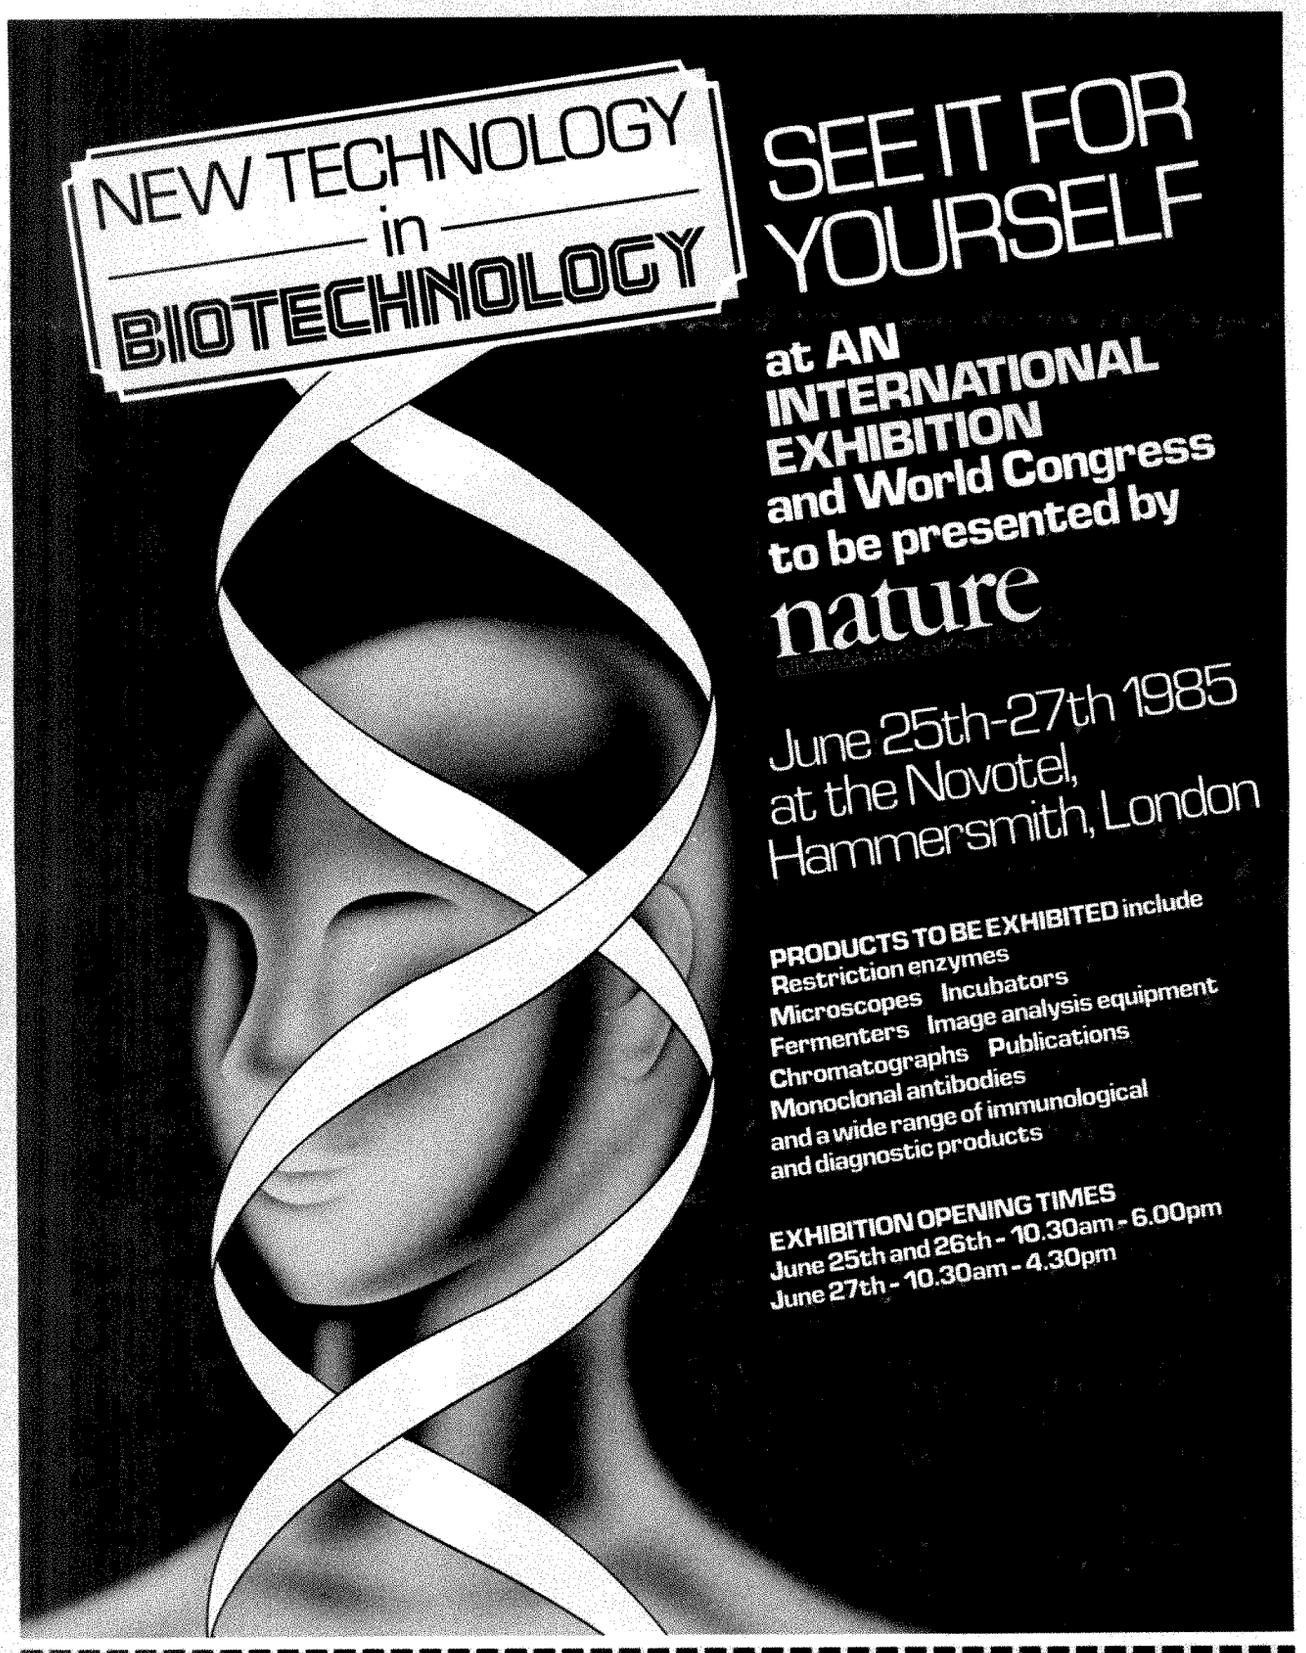
In addition, there will be two symposia on state-funded research and venture capital.

An international exhibition

Over 100 firms and research institutes will provide an insight into new biotechnological products and processes, as well as the latest developments in laboratory equipment and production techniques.

The European Community as agreed to support BIOTECHNICA '85, and will also be represented with a stand displaying the results of EC-funded research.

Come to BIOTECHNICA'85 Hanover for a detailed insight into current developments in biotechnology.



8th – 10th October, 1985
1st International Congress + Exhibition for Biotechnology

NEW TITLES IN THE

TOPICS IN MOLECULAR AND STRUCTURAL BIOLOGY SERIES

Series editors: Watson Fuller, Department of Physics, University of Keele.
Stephen Neidle, Department of Biophysics, Kings College, London.
Tony Atkinson, Microbial Technology Laboratory, PHLS Centre for Applied Microbiology and Research, Salisbury.

Volume 5 Connective Tissue Matrix

D. W. L. Hukins, Department of Medical Biophysics, University of Manchester

An introductory chapter details individual macromolecular components and following chapters are concerned with interacting systems of macromolecules in extracellular matrices and the ways in which they influence the mechanical, and hence biological, functions of connective tissue.

1984 256pp 0 333 33372 1 £35

Volume 6 Metalloproteins; Part One – Metal Proteins with Redox Roles

P. M. Harrison, Department of Biochemistry, University of Sheffield

Metals play important roles in a large number of biochemical reactions. These volumes explore those aspects of biochemistry which involve association of metal with protein. The metals concerned, principally iron, copper and molybdenum, belong to the transition metal series.

March 1985 272pp 0 333 33374 8 £35

Volume 7 Metalloproteins; Part Two – Metal Proteins with Non-Redox Roles

P. M. Harrison

This second volume on metalloproteins brings together six classes of protein to illustrate a variety of important physiological processes in which metals are involved in association with protein.

March 1985 352pp 0 333 33375 6 £45

Volume 8 Polysaccharides: Structure and Function

E. D. T. Atkins, H. H. Wills Physics Laboratory, University of Bristol

Polysaccharides are a group of complex carbohydrates including starch and cellulose, that are involved in a variety of ways in the structure and function of organisms. This book aims to review recent advances in the understanding of the structure of the major types of polysaccharide, stressing those of medical, biological and economic importance.

October 1985 250pp 0 333 33371 3 £35

Volume 9 Topics in Nucleic Acid Structure, Part 3

Stephen Neidle, Department of Biophysics, University of London

Forthcoming 1986 256pp 0 333 33376 4 £35

University paymasters discredited

The British government's latest policy document on higher education is a disgrace. Academics now have nothing to lose but the tenure of their jobs (itself proscribed).

THE British government's latest proposals for higher education (p.270) are most of all distinguished by their vacuity, the quality of being "content-free" in the newest civil service argot. The officials at the Department of Education and Science who have laboured for the past year and more to put flesh on the bones of Sir Keith Joseph's preconceptions about higher education and those who work therein have produced an agenda for a non-discussion, for interested parties to say where they have always stood while the cause they are supposed to share is lost.

Shabby is the best word for this literally appalling document, and calculated indifference is the only way of describing the policy it embodies. Ordinary innocents might suppose that a state paper with "*...higher education into the 1990s*" in its title might have something valuable to say about the function of higher education in contemporary society. Carefully, the draughtsmen of this latest prospectus for British universities and polytechnics give no hostages to fortune. They simply quote the Robbins report of 1963 and launch into a discussion of the role of higher education in "the production of qualified manpower".

That calculated indifference is the British goverment's policy in higher education is now made crystal clear. (The calculation is that if the government does nothing about the problems of higher education, they will solve themselves just as mail that is left unanswered is usually overtaken by events, in this connection the disappearance of a nuisance.) Thus the green paper stolidy dodges the question that higher education has been asking the British government for at least five years, that there should be a clear definition of its function. (The explanation that there can be no longer forecast of the funds that will be available to higher education than for, say, the Ministry of Defence, is an answer to a different question.) Instead, the green paper parades the need that institutions of higher education should look to other sources than the British government to keep themselves in being. Perhaps universities and polytechnics should take the hint and make a dash for freedom). That way, they might be better off.

The plain truth is that the British government has systematically misled British higher education. Although the once-and-for-all reduction of 8.5 per cent of university budgets decreed in 1980, together with the manipulation of the fees of overseas students whose variable effects were to reduce university incomes by an average of 5 per cent, was accompanied by promises that there would be "level funding" once the shock had been absorbed, the fact is that the budgets of the universities as a whole are still falling by between 1.5 per cent and 2 per cent a year in real terms. The polytechnics lie some two years behind on the path to penury, chiefly because of the delay in creating their supervisory National Advisory Body. During the same period, the government has put a ceiling on the numbers of students that universities and polytechnics separately are allowed to teach, has threatened a cumbersome procedure for denying academics the right to tenure of their jobs and has generally exhorted everyone in sight to find other sources of funds than the public purse.

Nobody should deny that the government has problems. In the prosperous early 1960s, it seemed sensible that there should be a public system of higher education to which all qualified would-be students should have access, which principle would determine the scale of the system. It also then seemed financially feasible that the central government should meet the cost to local authorities of maintenance grants for all students winning themselves a place in higher education. Even the present government's belief that British higher education is indolently unconcerned with Britain's chronic economic difficulties is not new, as shown by the decision during the 1964 Wilson government that the polytechnics should be designated as an alternative system of higher education, one more concerned with practical affairs.

Sourly, the present government has also allowed itself to be captivated by the belief that the whole of higher education is somehow corruptly innefficient. The green paper applauds the recent Jarrett inquiry into the management of six universities but ignores the first of its recommendations, that a prerequisite of efficiency is a coherent policy framework for higher education as a whole There may be something in the suspicion that British higher education could be operated more economically, although the most obvious diseconomies in the system now are those created by the government's own edicts of recent years. Preoccupied with these problems, the government has taken to behaving as if it wished that higher education would simply disappear. The green paper offers such perfunctory acknowledgement that the system now in being has merit that its readers may be forgiven for thinking that the government has no heart for the struggle to keep the system going.

The crunch will come quite soon. If real resources continue to decline by between 1.5 per cent and 2 per cent a year, whatever slack there is in the system will soon be exhausted. Then the grants committee and the advisory body will have to tell the government that the drain cannot continue within the present framework without striking some whole institutions off the public payroll. Prudent institutions, universities or polytechnics, will be well advised to get out of the system before that time comes. Reorganizing for independent survival is now the game. The green paper's list of alternative sponsors should (and will) be studied carefully, but there may be others, municipal authorities for example. Only the more depressed among institutions of higher education will ask why should they bother struggling to survive when their present sponsor is so plainly not merely indifferent but ignorant of their role. Some among the others will sense that the claims upon them consist not merely of inputs and outputs ("student demand" and "qualified manpower") but of young people sharing a common conception of what the future might be like; and that knowledge is neither for its own sake nor for the winning of prestige but for a civility that the author and originators of such a banal state document could not comprehend. Groucho Marx is known not to have wanted membership of a club that would let him in. Who, in scholarship and research, dares admit to sponsorship like this? □

Biological manuscripts

Miranda Robertson, Biological Sciences Editor of *Nature*, is now based in the Washington office of *Nature*. Manuscripts offered for publication may be sent, as at present, to either the London or the Washington office; with the benefit of good communications, the speed with which manuscripts are dealt will be independent of the place at which they are received. But authors are asked please in future to send **four copies of manuscripts** intended for publication (one for each office and two for referees).

High-energy physics

UK committee to push for CERN budget cuts

BRITAIN'S spending on high-energy physics is out of balance with its spending on other science, and must be reduced substantially, according to the committee set up last year to consider continued British membership of CERN (the European Organization for Nuclear Research). The committee, chaired by molecular biologist Sir John Kendrew, will report next week to the chairmen of the Advisory Board for the Research Councils (ABRC) and the Science and Engineering Research Council (SERC) that it has been impressed with the excellence of CERN's work, but that the organization's budget should be kept constant beyond 1990.

According to one figure being canvassed in the committee this week, the CERN budget could come down by 20-25 per cent after 1990 without substantially affecting the quality of CERN research, which by then will depend almost entirely on the running of the large electron-positron collider LEP and its extension to "phase II" 100-GeV operation But whether the final report will actually mention such a figure is uncertain. Committee members are anxious to avoid a conflict with their European partners in CERN, with whom they would like to seek an agreed reduction, and to quote 20-25 per cent might be counterproductive.

Indeed, French officials last week described a cut on such a scale as "likely to kill CERN, given that half their costs are salaries". The West German position is that a 25 per cent cut "could not be done fairly". Nevertheless both countries consider that some cuts are possible. Paris considers that cuts "of a few per cent" would not harm CERN, and Bonn that a 10 per cent by 1990 might be supportable.

Sir John Kendrew and members of his committee met the West German research minister, Heinz Riesenhuber, and the French research minister Hubert Curien, earlier this year, and were encouraged to learn that others might agree that CERN budgets should be trimmed. But the committee did not visit Italy, where the government recently doubled national spending on high-energy and nuclear physics and is in a mood to increase the CERN budget rather than decrease it.

The West Germans told Sir John that the government was more comfortable with the CERN contribution than Britain because certain other projects supported by the research ministry (BMFT) (such as nuclear energy) are decreasing in cost and because, overall, the ministry has been enjoying a roughly constant real budget. He also argued that the expenditure on research and development in most European nations (including Britain) had decreased as a fraction of gross national product over the past decade, so effective cuts had already taken place. A German committee on big projects under Klaus Pinkau had also set a high priority for CERN and for LEP. Nevertheless Germany is looking for savings.

Mandatory scales of contribution of the eleven member states of CERN, 1985-87:

	Percentage
West Germany	24.90
France	20.23
United Kingdom	16.91
Italy	13.56
The Netherlands	5.39
Spain	4.94
Sweden	4.01
Switzerland	3.87
Belgium	3.61
Denmark	1.98
Ireland	0.60

The CERN budget in 1985 amounts to SF 724.5 million (around £220 million).

Cuts could be found, according to Riesenhuber, in reductions of staff and salaries at CERN. (One complaint is that CERN salaries are so high that it is impossible to attract German scientists back to Germany. There is also, according to Riesenhuber, scope for rationalization of CERN management and in postponing in new investments (such as extending LEP to full performance). A 10 per cent cut by 1990 is "realistic", it is believed in Bonn.

At CERN, however, the prospect of cuts is faced with some horror. CERN director-general Professor Herwig Schopper would like to begin the extension of LEP to 100 GeV per beam as soon as technically possible, which with rapid advances in superconducting accelerating cavities means spending sooner than expected — in 1989. This would mean a small increase in CERN spending in the new five-year planning period.

There will also be a pensions problem. Schopper says that CERN council decided four years ago to increase staff pensions in line with those available in Switzerland, which will mean increased expenditure on personnel when the main retirement bulge begins in 1990. But CERN has not yet made the investments into the pension fund either to pay for these increases or to pay the basic pension. "Our actuaries tell us there is a 'technical deficit' ", says Schopper. CERN is indeed planning a reduction in personnel, and to make more use of outside contractors, but even then "it's unavoidable that there will be an increase in our personnel budget" because of the pension commitments. The only light on the horizon is that Spain will become a full member by 1989, increasing its contribution from the present 5 per cent to 7 per cent of the CERN budget, says Schopper.

For the Kendrew committee, the problem is that even a 10 per cent cut in the CERN contribution would not have provided the increased funding for other sciences that the committee believes necessary. Hence the mooted target of 20-25 per cent, and hence, no doubt, a propensity to be sceptical about Professor Schopper's claims.

Indeed, the feeling in the committee goes even further. First, an attempt should certainly be made first to reach agreement with European partners for a large reduction in the CERN budget. But if that fails, and if the hopes of some members are disappointed that collaboration with the United States will be feasible, the only option will be complete withdrawal from CERN. **Robert Walgate**

Caltech at war on star wars

Washington

MARVIN Goldberger, president of California Institute of Technology, has written to Secretary of Defense Caspar Weinberger taking exception to an announcement that Caltech had joined a "consortium" of universities carrying out star wars research. In his letter, Goldberger says that Caltech's only involvement in the $9 million contract announced by the Innovative Science and Technology (IST) division of the Strategic Defense Initiative organization for research on optical signal processing is a single $50,000 subcontract to one Caltech scientist from the University of Dayton Research Institute.

A press release put out by the IST office announced the "formation of a consortium of several institutes," including Carnegie Mellon, Stanford and Massachusetts Institute of Technology.

Caltech has yet to approve the contract. Both Caltech and Stanford have also expressed concern about news reports that the work would be classified. But according to Dr James Ionson, who heads the IST office, all the work would be totally free of classification or other restrictions in accordance with Department of Defense policy on basic research that is conducted on campus.

Ionson defended the use of the term "consortium", saying that the scientists involved had worked together on the proposal, which was submitted by the University of Dayton and the University of Alabama at Huntsville. "The important news is that some of the most prestigious individual scientists are working together for a common goal", he said. As to Goldberger, "It's no secret that he's not an advocate of SDI." Stephen Budiansky

UK laboratory animals

New legislation forecast

THE British government has taken a further step towards tighter legislation on animal experiments in a second White Paper (policy document) on *Scientific procedures on living animals*, published last week by the Home Office, the government department responsible (Cmnd 9521, HMSO, £3.30). The document is said to be the result of collaboration between the government, scientists and the "realistic element of the animal welfare movement". The main changes from the earlier proposals (see *Nature* **303**, 191; 1983) are: tighter controls on the severity of procedures; modification of the project licensing assessment system; improvements in laboratory animal care; higher penalties for some offences.

Under the new proposals, investigators will need two separate licences, both a personal licence betokening general competence and a project licence for each proposed investigation. Applicants for both kinds of licence must provide the Home Secretary with detailed information about themselves and their proposed work, together with the names of persons willing to act as sponsors. For a personal licence, the sponsor will vouch for the applicant's "competence and integrity". For project licences, the sponsor will give a detailed opinion of the scientific merits of the project and techniques to be used. The white paper says that a field trial has shown that such a system would work in practice. But because of the practical difficulties of assessing all project licence applications in this way, the Home Office now proposed to refer only those projects where the scientific quality of the work is in doubt to an independent assessor.

Criteria for obtaining a licence under the proposed regime will be stricter than at present. The Home Secretary must be persuaded that the work is justifiable, that no satisfactory alternative to the use of animals is available, that the minimum number of animals is used and that the least possible suffering is caused.

Considerable emphasis is placed on the severity of pain, which will be balanced against potential benefit when project licence applications are considered. Such a cost-benefit principle has been widely advocated, in particular by Sir Andrew Huxley, president of the Royal Society, who suggested a graded approach to the justification of experiments on animals in his anniversary address to the Royal Society last year.

The new white paper is an excellent compromise in the debate on animal experimentation, Sir Andrew said this week. The licensing system will make clear who is responsible for a project, and the form of permission for project licences will ensure that granting a licence does not become a "rubber stamp procedure".

In practice, the Home Office will issue personal licences which will, in effect, be a certificate of competence to a particular investigator to pursue a particular project. But project licences will be issued only to applicants "who can satisfy the criterion of permissible purpose". The Home Secretary will impose conditions setting "permissible degrees of severity (of pain) for that project . mild, moderate and substantial". Home Office inspectors will have increased power to order humane killings, "action to be taken at the onset of various signs" such as loss of motor function. The new proposals also require painless killing at the end of a predetermined period, administration of analgesic and constant supervision throughout the procedure.

Before a project licence will be granted, the applicant must agree with the Home Secretary on the likely level of severity of pain an notify an inspector if this forecast is likely to be exceeded. The Home Secretary will decide how the categories of pain are to be defined and applied, and will publish guidelines to inform applicants, licensees and the general public of how the proposals are intended to work.

An animal procedures committee is being set up to advise the government on policy, on applications for research causing "special concern" and on the testing of cosmetics. The committee is chaired by Baroness Warnock and its members include scientists, representatives of organizations that protect animals and representatives of pharmaceutical companies.

The composition of the committee, however, emphasizes the government's commitment to regulated experiments on animals. As Sir Andrew pointed out, the situation cannot arise where experiments can be stopped by a block vote of anti-experimentalists on the committee, which answers the genuine worries of many biological and medical scientists.

Reactions to the white paper are mixed. The Association of British Pharmaceutical Industries accepts the need to update the existing (1876) legislation, but is concerned that there will be "too narrow a definition of the scope of the project licensing provisions". The Humane Research Trust and the British Veterinary Association welcome the proposals in the main. The British Union for the Abolition of Vivisection calls them a "confidence trick" and a "vivisectionists' charter".

The number of experiments on animals in the United Kingdom has fallen from 5.6 million in 1971 to 3.6 million in 1983. In 1985 the Humane Research Trust will give grants of £100,000 to nineteen investigators using alternative experimental procedures that do not animals, and the pharmaceutical industries will spend £10-12 million on development of non-animal techniques in drug testing.

Maxine Clarke

US laboratory animals

NIH watchdog committees

Washington

LABORATORY animal research at publicly supported institutions in the United States will from November this year have to be overseen by special "animal use" committees that will include at least one lay representative, according to new guidelines issued by the Department of Health and Human Services. The guidelines charge the animal use committees with responsibility for reviewing research programmes and inspecting laboratories and animal houses at least annually. Research that does not meet the committees' standards can be stopped.

The requirement that each committee should include at least one lay member is welcomed by animal welfare campaigners, but some had hoped for a representative concerned specifically with welfare. Welfare champions are unhappy that the committees are not required to review in detail research protocols for investigations in which non-trivial pain may be caused.

Christine Stephens, president of the Animal Welfare Institute, says that this omission is a "profound disappointment". Earlier proposals had required special approval by the committee for non-routine or harmful invasive procedures, procedures involving prolonged restraint, diseases maintained for long periods or non-standard methods of euthanasia. The new proposals leave it to committee members to decide if special attention is warranted. Ms Stephens is also disturbed that institutions can apparently apply for a retroactive waiver that would release them from their responsibilities under the new guidelines.

The Association of American Universities, in contrast, is relieved that lay members will not be required to review research protocols, a requirement that the association considers "unacceptable".

The guidelines do not have the force of law, although an institution could in theory lose its financial support if deficiencies went uncorrected for long enough. Critics point out, however, that such an occurrence is almost unknown. The National Institutes of Health are still investigating allegations of mistreatment of baboons used in head injury experiments at the University of Pennsylvania; despite the widespread availability of a video tape showing apparent mistreatment, which was last week being shown to members of Congress, the research is still being supported. A bill introduced in the last Congress by Senator Robert Dole and Representative George Brown would have given statutory force to animal use committees: a new version of the bill is likely to be introduced in Congress within the next few weeks.

Tim Beardsley

DNA probes

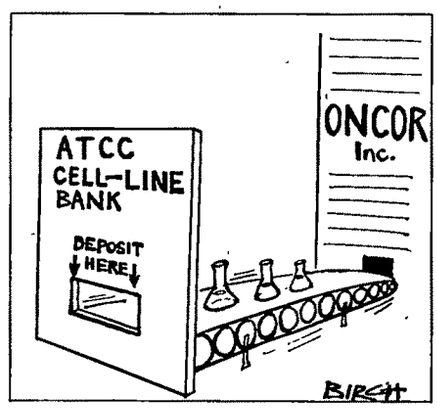
Type culture a source of gain

Washington

THE role of the American Type Culture Collection (ATCC) as a repository of materials for basic biological rsearch is being threatened, researchers say, by commercial exploitation of cell lines deposited there. At least one molecular biologist has refused to send any more of his samples to the collection after a commercial company obtained an oncogene he had deposited and, without his knowledge, began marketing to researchers DNA probes derived from it.

ATCC, a non-profit organization, makes cell lines and other materials in its collection available to any qualified researcher who requests them, charging a nominal fee to cover its costs. Although primarily a service to basic researchers, the collection has played an increasingly important role in facilitating the patenting of recombinant DNA products and processes.

As a general rule, the Patent Office requires applicants to deposit novel cell lines or plasmids in a collection such as ATCC to satisfy the public disclosure requirements of patents — the traditional written descriptions are often insufficient to allow someone else to reproduce the invention, a fundamental requirement of patent law. In order to satisfy the legal requirements, no restrictions on the distribution of deposited materials can be imposed.



But that totally unrestricted distribution is upsetting some basic researchers. Tom Curran, a molecular biologist at Hoffmann-La Roche, recently deposited a cell line containing the *fos* oncogene, which he had isolated when he was a graduate student at the Imperial Cancer Research Fund Laboratories in London, in collaboration with Inder Verma of the Salk Institute.

Curran says he was subsequently "shocked and distressed" to discover an advertisement in *Nature* from Oncor Inc. for DNA probes for a variety of oncogenes, including *fos*. Curran says Oncor did not even inform him that it had obtained the sample from ATCC or that it was planning to market his product. He says his primary objection is that Oncor is making a profit by selling to basic researchers a product developed by basic research in which the company had no part. Curran says he deposited the oncogene with ATCC so that it would be "freely available to the scientific community".

Some research groups, apparently concerned about the uncontrolled commercial exploitation of cell lines placed in the public domain through ATCC or otherwise, have taken to distributing samples themselves to other basic researchers and requiring a signed agreement that those receiving them will not pass them on to a third party or exploit them commercially without permission. Although there is some dispute over the enforceability of such agreements at law, in at least one well-publicized case, that of David Golde's KG-1 cell line, the originators of the cell line won a sizeable out-of-court settlement from a company that had obtained and was using the material without their permission (see *Nature* **301**, 6; 1983).

Bobbie Brandon of ATCC says that the collection may have to reconsider its policies on free distribution, but that it would not want to be in the position to enforce restrictions against transfers or commercial development. And, although she sympathizes with Curran's complaints, she says Curran had signed a statement agreeing that ATCC could make the oncogene available to anyone requesting it. Brandon says that ATCC distributes about 1,000 oncogene samples each year at a cost of $64 to commercial organizations and $44 to non-profit groups.

Steven Turner, founder and chief executive officer of Oncor, says he sees nothing wrong with the service that his company is providing and that his company's contribution is by no means trivial, as Curran suggests. "We're not just taking the ATCC strain and dropping it into tin cans and selling it", he says. Turner adds that the customers for the products are not basic molecular biologists, but rather clinical researchers who do not have the means to develop the probes themselves from the material available from ATCC. And he says that strains deposited in ATCC are in fact not very attractive for commercial development because they are in the public domain: "I have no protection with what I do with that strain".

Turner, who was the founder of Bethesda Research Laboratories before founding Oncor two years ago, says, "I long ago got used to the hypocrisy of academics saying that their activities are on a higher moral plane than business". While academic researchers refuse to sell their cell lines, they nevertheless demand a *quid pro quo*, such as demanding that the recipients "stick their names on your papers for the next five years". "I've never seen exploitation as I've seen it performed in academic labs."

Stephen Budiansky

Sakharov

Birthday award from US centre

Washington

THE Andrei Sakharov Institute in Washington, founded five years ago to honour the Soviet academician and human rights campaigner, this year added a new feature to the now-traditional Sakharov birthday celebrations — an annual prize for science. The first recipient is Dr Aleksandr Esenin-Volpin, a mathematical logician, for many years a human rights campaigner and a victim of psychiatric repression in the Soviet Union, before he was "persuaded" to emigrate in 1972.

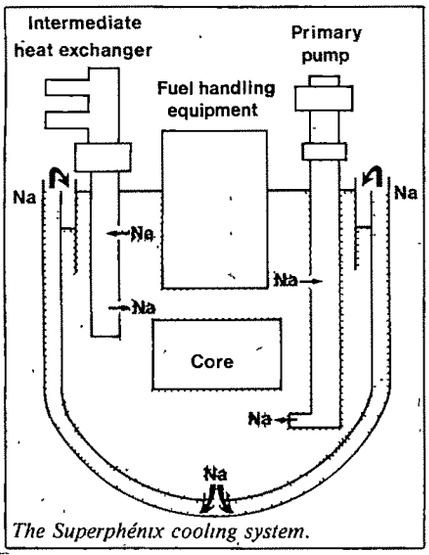
The prize this year is modest, a mere $5,000, and the decision to establish it was taken only two weeks before the event. Vladimir Bukovskii, himself a former human rights campaigner and psychiatric victim, said in announcing the award that the funds were largely collected from Russian emigres in the United States, many of whom are not well-off. But in view of the number and distinction of the universities and institutions from which the "advisory board" of the Sakharov Institute is drawn, and the recent introduction of a congressional bill to grant it a federal charter, there is every hope that a more substantial sum may be available next year.

The prize is not the institute's first educational venture. In addition to its Center for Democracy, which aims at propagating Sakharov's ideas on peace and democracy and publishing in English the works of authors unable to express themselves freely in their own countries, it also maintains an education and research section, which has been adopted as the Washington Campus of Long Island University. This has two major projects in hand, the improvement of the quantity of mathematics and science education in the United States (including the establishment of a National School for Science and Mathematics for Gifted Students) and the upgrading of the quality of Soviet and East European studies.

The announcement of the new prize added an optimistic note to last week's Sakharov "birthday" conference (held a few days before the actual date, 21 May), which otherwise concentrated on current progress (or the lack of it) in international acceptance of Sakharov's views on peace, arms control and human rights.

Inevitably, the issue was raised of plans to renew contacts between the US National Academy of Sciences and the Academy of Sciences of the USSR (see *Nature* 16 May, p.169). Since the National Academy broke off relations with the Soviet Academy in protest at Sakharov's internal exile to Gor'kii, it is not surprising that those gathered to honour him felt that there should be no new approach to the Soviets while Sakharov and his wife remain in exile.

Vera Rich



Fast reactors

Superphénix vibrations solved

VIBRATION problems in the primary sodium cooling circuit of the Superphénix European commercial-scale fast breeder reactor "have been solved or nearly so", and will not delay the fuelling of the reactor as had been feared, senior officials at the French Commissariat à l'Energie Atomique (CEA) said last week.

Thus the 1-200 MW(e) Superphénix, which has been built at Creys-Malville on the Rhône by a consortium in which the French and Italians are the major shareholders, with West Germany third, will still be loaded with plutonium at the beginning of September and produce its first fast neutrons soon after, according to CEA.

The problem now considered all but solved has been with an inner jacket of the main reactor vessel, which is little more than a tank full of liquid sodium, topped up with an inert argon atmosphere. As part-

The Superphénix cooling system.

of the cooling circuit, a thin film of sodium passes upwards from the bottom of the main vessel around the outside of the inner jacket, before spilling inwards over the lip of the inner jacket into the core of the reactor. In the first live tests of the cooling system full of heated sodium, the jacket was vibrating with an amplitude of some 12 mm in a diameter of 20 m.

It seems, however, that CEA will now go ahead with the fuel loading without modifying the reactor. Engineers at Creys-Malville have found that a slight adjustment to the sodium flow rate will stop the vibration. The key factor, according to CEA, was the height through which the sodium fell when cascading over the lip of the inner jacket. Initially 100-150 cm, this "sodium fall" has been reduced to 30-60 cm by increasing the volume of sodium in the reactor (by 200 tons) and slightly increasing the flow rate between the inner and outer jackets.

Meanwhile discussions continue in Europe over, first, where to site a planned second fast-breeder reactor, with West Germany and France the main contenders, and second, where to place a single fast fuel reprocessing plant, with the main contenders being France and the United Kingdom. CEA sources believe that a decision on the site and detailed design of a second breeder is necessary by 1987, and that only France could be ready by that date. The potential purchasers, the French national electricity utility Electricité de France, however, which will probably have a large surplus of electricity by the end of the decade, is not thought to be quite so keen. **Robert Walgate**

Belgian research

Autonomy sacrificed to regions

Brussels

REGIONAL tensions in Belgium are eroding the autonomy previously enjoyed by the quasi-governmental institute for the encouragement of scientific research in industry and agriculture (IRSIA). Hitherto, the institute has been free to select areas and projects for applied industrial research, but now its freedom will be further limited by the latest separate decisions of the fiercely competitive Flemish and Walloon regional ministers to increase their influence on its affairs.

Last month, the president of the Flemish regional executive, Gaston Geens, announced that IRSIA would from now on have to submit projects received from Flemish companies for approval to a commission directly under the control of the minister of economics before funds could be granted. It is also required that one-third the of money available should be specifically set aside for small and medium-sized companies, that a certain amount should also be earmarked for projects specified by the regional executive and that all Flemish companies would have to pay back subsidies obtained from IRSIA when the products of research reach the commercialization stage.

Until now IRSIA has always believed in a system of non-repayable subsidies on the basis of a 53 per cent average participation for regular projects and 80 per cent for first ventures, with success and quality governing future eligibility. The old system remains in force in the Walloon and Brussels regions.

The new Flemish system, it is feared, could have the double effect of wilful under-estimation of results by companies to avoid repayment of the loan and could even restrict technological innovation.

Since 1983, when research was defined in terms of the 1980 Belgian regionalization laws, IRSIA has become used to administering separate coffers (the proportional distribution system was revised in August 1984 to try to give each region its fair share). The major industrial sectors of Belgium — glass, textiles, coal, steel and construction — have not been affected by regionalization, and nor have large companies and collective research centres, but IRSIA previously supported small companies not only with money but also with information on research activities elsewhere. Regional separation has meant that research activities are suffering both restrictions and overlap. It has also put IRSIA in a very delicate position: it receives applications and oversees projects from all regions but it has to keep information about research developments in each completely separate.

As well as making extra administrative work for IRSIA, the latest decisions also risk fragmenting the applied research effort in Belgium as a whole. This seems ironic at a time when the European Commission, in the Belgian capital, Brussels, is urging the ten member states of the European Community to make easier the mobility of workers, the exchange of information and cooperation on research. **Anna Lubinska**

Fetal diagnosis trial

CHORION villus sampling, a new technique by which genetic fetal abnormalities can be detected as early as eight weeks of pregnancy, is to be evaluated in a three-year clinical trial run by the British Medical Research Council (MRC). Amniocentesis, the usual method for prenatal diagnosis of genetic disorders, has the disadvantages of being performed later in pregnancy (about 15 weeks) and, because cells have to be grown in the laboratory, the results are generally not available for a further four weeks.

In chorion villus sampling, a sample of placenta containing fetal tissue is removed, allowing immediate diagnosis and much earlier termination. But the technique may be less safe. Preliminary indications (using the 3-400 tests performed so far in the United Kingdom) suggest that the spontaneous abortion rate is 2-5 per cent, compared with 0.5-1.5 per cent in amniocentesis. The randomized trial will include 4,000 women in the United Kingdom and is based on the informed consent of women who elect to join the scheme. Between 10 and 20 UK and European centres will take part; the study will be coordinaed with Canadian and US trials. MRC will also follow up the children born after the prenatal trial to assess for any long-term effects of the technique.

Diseases such as Down's syndrome, anaemias, haemophilias and phenylketonuria can be identified by prenatal sampling; soon muscular dystrophies and cystic fibrosis will be detectable as genetic probes become available. Maxine Clarke

UK higher education

Help business and survive

THE British government's long-promised Green Paper (discussion document) on higher education, published earlier this week (Cmnd 9524, HMSO, £5.80), does nothing to suggest that the pressure on university and polytechnic budgets will be relieved. Indeed, the government says that planning for the impending fall in student numbers, expected on demographic grounds in the 1990s, "will need to begin shortly". The document says that these changes will require "not only rationalization within institutions but the amalgamation or closure of whole institutions".

The document says that there is a need for "means of assessing, on educational and economic grounds", where capacity should be reduced, promises that the chief advisory bodies (the University Grants Committee, UGC, and the National Advisory Body, NAB, which represents the polytechnics), will "have a key role" and adds that "the government will be fully engaged". The government notes the pleas of both bodies as well as of the Jarrett committee on university administration (see *Nature* 4 April, p.392) that institutions should be given longer notice of the public funds at their disposal, but says that its three-year rolling forecasts are the most it can provide, and that higher education institutions should be able to accommodate "change and some inevitable uncertainty".

To most academics, the green paper will be a disappointment, not for what it says or neglects to say but for its tone. The keynote is the statement in the introductory section that "the government believes it is vital for our higher education to contribute more effectively to the improvement of the performance of the economy". Referring to its own initiatives to improve the quality of science teaching in schools, the government says that there "would be no point in continuing to provide more places in science and technology in higher education" unless there are enough able students to fill them, urges that universities and polytechnics should plan for flexibility in the face of change and demands that "higher education establishments" should abandon "anti-business snobbery" and, instead, should foster entrepreneurship, should "go out and develop" links with industry and commerce and should form strong connections with local communities.

With qualifications, the green paper accepts the redefinition by UGC and NAB of the principle that suitably qualified students should have access to higher education (the "Robbins principle") by agreeing that "courses of higher education should be available to all those who can benefit from them and who wish to do so". The qualification is that "so long as taxpayers substantially finance higher education . . . the benefit has to be sufficient to justify the cost". The "test of ability to benefit" should be applied as stringently to those with formal qualifications as to those without.

Inevitably, the green paper rehearses the government's position on the future demand by students for places in higher education, but promises a more considered estimate of demand after a survey now being carried out among young people. Meanwhile, it says, the funds now promised should suffice to allow universities and polytechnics to meet the demands on them in the three years ahead. The document says that UGC and NAB have been asked to recommend how students should be distributed between the universities and the polytechnics, but asks that students should not be admitted to universities if they are more likely to benefit "in terms of personal development and future employment prospects" from a course at a polytechnic.

On research, the green paper rejects the argument of UGC that "research stimulates the teaching of able students" with the statement that "there is no evidence that all academic staff must engage in research". It applauds UGC's plan to distribute research support selectively, hopes that a start will be made in 1986–87 and notes that one consequence may be that "some departments or even whole universities will lose research funding (*sic*) from the UGC". The green paper says that universities will still be free to seek the funds from private sources.

With more enthusiasm, the green paper argues the benefits that would accrue to academics and to "business" from a closer relationship between them, and urges academic institutions to take account of industrial consultancies when assessing candidates for promotion, to encourage academics to "engage in business activity", if necessary on part-time academic contracts, to strike "reasonable deals" with staff over the income earned from innovations and to operate industrial liaison services. (Cautiously, the green paper warns academic institutions of their potential insurance liabilities in these activities.) In the same spirit, the government says it has asked UGC that success in industrial collaboration should be given "due recognition".

The green paper also says the government is not convinced that two-year degree courses are feasible, but would like to see them tried, and that it is dismayed at the growth of the numbers of students now following four-year courses. The paper also says that the government is planning to construct measures of performance for higher education institutions, and that it wishes there to be a uniform system of validation of university courses. On academic tenure, the green paper says that the academic freedom of those who lack this privilege "is not visibly under threat". There is to be an inquiry into the role of UGC.

One of the recurrent themes of the green paper is the right of free speech within universities, and the government promises a reconsideration of the degree to which students' unions should be financed from public funds. Meanwhile, it asks that universities and polytechnics should do what they can to prevent students from suppressing unpopular views. □

Interferon

Agreement on marketing

Washington

HOFFMANN-LaRoche Inc. and Schering-Plough corporation have reached a truce in their battle over marketing rights for human leukocyte (alpha) interferon (see *Nature* 21 March, p.207). Under the terms of agreements reached last week, Schering-Plough will pay royalties to Roche if Schering-Plough's product is sold in the US market, while in Europe each will be free to sell its own product without infringing the other's patent rights. Terms for Japan are expected to be similar to those covering the United States.

Schering-Plough's interferon (trademarked Intron) is produced under licence from Biogen NV of Cambridge, Massachusetts and Geneva, Switzerland. Biogen holds a European product patent for alpha interferon produced by recombinant techniques and expects to receive a similar patent in the United States. Roche, however, holds a very broad US patent that covers all highly pure human leukocyte interferons, and the new agreements recognize that Schering-Plough's product falls within the terms of the Roche patent.

The agreements mean that recombinant interferons will be commercially available while the patent claims are sorted out. Roche has challenged Biogen's European product patent and that challenge will be pursued despite the agreement that both can market their products; the outcome would be important if either company decided voluntarily to withdraw from the market, for example. In the United States, where both Intron and Roche's "Roferon-A" alpha interferon are in clinical trials, the final outcome of the dispute will hang on the scope of the expected Biogen patent for recombinant alpha interferon. The agreements refer only to a specific type of alpha interferon, however; if other variants prove to have valuable properties, there could be more battles to come. In addition, both beta and gamma interferons are in clinical trials and marketing rights for them are likely to be keenly contested.

Tim Beardsley

UK research

Despairing demand for more

THE Oliver Twist of British civil science, the Advisory Board for the Research Councils (ABRC), has this year asked for more in even stronger language. The preface to the annual claim for research funds, agreed by the board at its meeting at the end of April and now on its way to Sir Keith Joseph, the Secretary of State for Education and Science, says that "Parliament, the government and the country as a whole" are "complacent" about the present condition of the dual support system, the means by which support for university research is channelled through the research council and the University Grants Committee.

ABRC says that this complacency is born of a misconception of the function of the research councils and of basic research as such. The board thinks it necessary to point out that it is not true to say that the research councils support only research for its own sake and that academic research is remote from the real world.

As in previous annual applications for funds, ABRC acknowledges that there are limits to what can be afforded for basic research. But it insists that the government which ultimately foots the bill cannot expect that new technologies will emerge unless there is basic science from which they can spring. The board's application also argues that the pace of scientific advance is now such that copying other innovative technology is no longer a recipe for industrial success.

Part of the board's difficulty, this year as previously, is that the government appears on the face of things to have kept the Prime Minister's promise in 1980 that the research budget would be "protected". Using the retail price index as a measure of inflation, the science budget has in fact increased by 6.4 per cent since 1981-82. Even allowing for the decline of the research councils' other income, mostly by way of research commissions from government departments, amounting to roughly 7 per cent on a sixth of the total science budget during the same period, the total income of the research councils has increased by roughly four per cent.

The board says that this simple arithmetic is misleading partly because the retail price index is not a good measure of the increased cost of research. Rather, the board calculates that the real volume of research supported with the funds within its purview has declined by 5 per cent over four years. Matters have been made worse, the argument continues, by the 8 per cent reduction (in real terms) of the budget of the University Grants Committee.

The case is sustained by a harrowing account of the changes which have been brought about within the research council system in the past few years. The total staff of the five research councils has declined by a fifth, by 2,000. But in general, ABRC says, the councils have found that the rate at which they are able to fire or redeploy staff is itself constrained by their shrinking budgets.

The consequences of this state of affairs are catalogued in detail. Thus, the submission to the government is believed to say, the Science and Engineering Research Council is no longer able to make full use of new facilities because it cannot afford the research equipment, is having to pass up opportunities for international collaboration for lack of funds, is unable to meet its commitments (to other government agencies) to encourage information technology and cannot give adequate support to several named areas of research of vital industrial promise.

Other lost opportunities cited by ABRC include the Medical Research Council's incapacity to provide more than half the equipment needed for a new programme of research in protein engineering at the Laboratory of Molecular Laboratory at Cambridge, the Natural Environment Research Council's incapacity to participate in the new ocean drilling programme and the incapacity of the Agricultural and Food Research Council to afford more than a third of the cost of replacing outdated research equipment.

By comparison with previous submissions, the latest request for more research money is terse, almost despairing, as if it had been judged imprudent that an unwilling government should be confused with a plethora of facts. ABRC will protest separately about the way in which the budget of the Agricultural and Food Research Council has been cut by £5 million this year and by twice as much in succeeding years because of a Treasury edict. Meanwhile, ABRC's modest request of government is £15 million for the year beginning next April, twice as much in the succeeding year and £40 million in 1988-89.

On past form, ABRC's submission and the response to it will be published in the autumn. □

UK neuroscience

New lab, old unit in new role

BRITISH neuroscience was given a much-needed fillip last Friday with the inauguration of the new £25-million Merck Sharp & Dohme Neuroscience Research Centre near Harlow, Essex, which is dedicated to investigating chemical transmission processes in the brain. The hope is that one outcome will be the development of new drugs for treating neurological and mental disorders. The centre is at present paying particular attention to senile dementia (Alzheimer's disease) and inhibitory pathways.

The centre is directed by Dr L.L. Iversen, formerly head of the Medical Research Council (MRC) Neurochemical Pharmacology Unit at Cambridge. It will eventually employ about 160 professionals and 50-60 support staff, making it one of the largest brain research centres in the world. It comprises departments of medicinal chemistry, biochemistry and pharmacology, including neurophysiology and animal behaviour, but project teams will be interdisciplinary, involving staff from various departments.

Iversen emphasizes the goal of designing drugs based on a knowledge of the structure and function of the membrane receptor sites for the appropriate transmitter chemicals, instead of the empirical synthesis of chemicals which are then screened for their effects on behaviour. The centre also includes a small clinical research unit to undertake preliminary trials of new drugs. There will be collaboration with universities, particularly under research council schemes for joint direction of research studentships, and with hospitals.

According to Merck Sharp & Dohme, the centre has been established in Britain because of the "pathfinding leadership of British scientists in brain research". Its existence should provide much-needed encouragement to the younger generation of British neuroscientists. The grim job prospects in academic research are resulting in fewer good students going into neurosciences and many that do are leaving Britain after their training. The centre has already attracted several younger scientists back from the United States.

Meanwhile, the Neurochemical Pharmacology Unit at Cambridge, threatened with closure a year ago, has been reborn. After a controversial two-year search to replace Dr Iversen as head of the unit (see *Nature* **309**, 486; 1984), MRC has appointed Professor E. Barnard of the Biochemistry Department, Imperial College, London, as the new director of the unit, now to be known as the Molecular Neurobiology Unit, from 1 October. In the same building as the MRC's Laboratory of Molecular Biology in Cambridge, Barnard's laboratory is intended as the focus in Britain of the use of molecular genetics techniques to study neurotransmitters.

The new unit will have two main lines of research — the development of animal models for the study of muscular dystrophy and motor neurone disease, and the cloning of brain receptors and their genes, in particular in nicotinic acetylcholine receptor and receptors for neuropeptides such as enkephalins and substance P. At full strength the unit will comprise five senior scientists and about 35 visitors, post-doctoral fellows, students and technicians.

Jennifer Altman

More on nuclear winter

SIR — The intrinsic ambiguity of numerical simulations of atmosphere processes guarantees a protracted controversy about the phenomenon popularly called "nuclear winter", as for example described by Turco *et al*[1].

There are, however, ways of injecting large masses of soot into the high atmosphere that are phenomenologically more explicit than those now described. It is necessary only to tell a systems programmer where one guesses the source of carbon should be and to ask him or her please to adjust the computer model accordingly. Consider targeting a coalfield.

The integration of biomass over geological time has endowed millions of square kilometres of the Earth's surface with fossil fuel loadings in the range from 100 to 10,000 g cm^{-2} (ref. 2), compared with the 1 to 50 g cm^{-2} that constitutes the carbon budget of the rural and urban fires in ref. 1. An unknown fraction of this ubiquitous coal, lignite, oil shale and peat is either exposed or lies beneath a thin veneer of overburden[3], and is at risk of interaction with energetic phenomena, including thermonuclear surface bursts and cataclysmic volcanism.

Warheads with yields in excess of 0.5 megatons detonated in such carbonaceous terrain can promptly transform the ground beneath into a mixture of carbonaceous plasma and particulates launched towards the stratosphere by direct entrainment in the rising fireballs. Efficiencies of roughly 10 to 100 megatons of soot per gigaton exploded seem likely (J. Nuckolls and L. Wood, personal communication). It should be noted that NATO (North Atlantic Treaty Organisation) and Warsaw Pact missile fields and fossil fuel fields are partially coextensive, as are the loci of cataclysmic calderas and the massive (trillion ton) hydrocarbon resources that occupy ≥ 10 per cent by area of the western United States.

Every few hundred thousand years, that region is host to a randomly located eruption of 250 to 2,500 cubic kilometres of incandescent tephra. Dr Turco has expressed his willingness to accept the largest of these events as analogues in their climatic impact to the dust baseline of ref. 1. In recent geological history, these eruptions have eviscerated about 5 per cent of the area in question. The worst-case scenarios arising from the interaction of caldera volcanism and fossil fuels involve both carbon and energy budgets that dwarf its inputs of nuclear winter. What were the consequences — local or global, mild or catastrophic?

A survey of the extent of their geological events and of their palaeoecological consequences might serve to illuminate the extent to which the nuclear winter model is a valid predictor of the fate of the Earth. Since a rough calculation yields a mean time of rather less than 10 million years between events capable of producing catastrophic natural carbon injections, the fact that we are not extinct may be germane to the present controversy.

It remains to be seen whether the neologism "nuclear winter" will ever qualify as what philosophers of language call a "rigid designator in the real set", two examples of which are "Carbon County, Wyoming" and "The Yellowstone Caldera". I do not mean to consign "the nuclear winter" to the null set, exemplified by "the canals of Mars" and "the unicorn", but merely wish to point out that a fossil rhinoceros in the hand is more amenable to analysis than two unicorns in the software, and that a diligent search of the fossil record has turned up many a rough beast in the past.

Nullius in verba

SIR — In your reference to the motto of the Royal Society (*Nature* 2 May, p.9) you make two mistakes. First you misquote the motto itself, and then you give a totally false translation.

The motto is *Nullius in verba*, the word *nullius* being the genitive whereas you give *nullus*, the nominative.

Admittedly, the meaning of the motto is obscure until one knows the rest of the line of Horace (*Epistolae*, I, i, line 14) from which the words are taken. This reads: *Nullius addictus jurare in verba magistri*, which may be translated as "Not committed to swearing by the words of any master". Here Horace declares to his patron Maecenas his own attitude to authority, and it is this rejection of authority as a source of truth that the Royal Society expresses in its motto. Your translation, "nothing in words", is wide of the mark.

Mass extinctions

SIR — Coming when it did, Michael Benton's article in News and Views (*Nature* 11 April, p.496) must have appeared like manna from heaven to the hundreds of geology and zoology undergraduates throughout the country, and presumably at his institution too, preparing for their final examinations this summer.

It is therefore important to note that Benton chose not to include the single most parsimonious hypothesis underlying the phenomenon of mass extinctions, namely that extinction events are the result of any number of external but unrelated causes which, as a result of simple probability, appear to occur with regularity.

Whether he likes it or not, this single hypothesis, concerned as it is with historic events, will perpetually thwart any attempts to falsify it. The demonstration of cyclicity paralleling these events does not establish a cause/effect relationship. The isolation of a likely cause in one or two cases cannot be extrapolated to the whole. Similarly, the prediction of the cause of the next is not going to help the debate now.

We are left with five explanations for mass extinction cycles. Arguments for and against each view, though futile, will continue. More detailed analyses of the fossil data, and refinements in dating events in the geological past, will not help us to decide which view is correct, though they may enable us to say which is most likely.

Future of RGO

SIR — Philip Campbell commented in *Nature* (28 March, p.303) that the staffs of the Royal Greenwich Observatory (RGO) and the Royal Observatory Edinburgh would greet with weary shrugs of resignation the news that the Science and Engineering Research Council (SERC) is to set up yet another committee to decide their future.

Dr Campbell is right in the sense that we have been subjected to so many of these exercises, this will be the fourth since 1983, that much time which should have been spent on observatory projects has been dissipated in justifying our existence.

The staff of this observatory are certainly not, however, facing SERC's latest investigation in a spirit of resignation. On the contrary, we believe that what we have achieved and are continuing to achieve in spite of under-funding and uncertainty is proof that RGO is a viable and efficient base for the support of astronomical research for the United Kingdom and its international partners.

Moreover, the scientific damage likely to be caused by any major disruptions at this stage when we are completing the new observatory on La Palma is too serious to contemplate with anything approaching resignation. The staff at RGO will be entering into discussions on the situation with vigour and determination.

Trailing AIDS in Central Africa

A meeting in Senegal enabled AIDS researchers to learn more of the possible African origin of the virus that causes AIDS and virus-associated cancers in Africa.

BECAUSE of growing evidence that the virus that causes acquired immune deficiency syndrome (AIDS) originated in Central Africa, AIDS researchers are turning to their atlases. Earlier this month, on 8-10 May, some landed there for the first time to attend a meeting arranged by the French Association pour la Recherche sur le Cancer at the faculty of medicine in Dakar, Senegal, on virus-associated cancers in Africa. What they were forcibly reminded of is that in African terms, AIDS is an insignificant problem, but that most common forms of cancer in Africa are caused in part by viruses.

At times the question of the origin of AIDS has seemed to be no more than a matter of geographical buck-passing — first between the United States and Haiti and then to and within Africa — but the issue is much more serious. At its worst, the argument is that the virus (HTLV-III or LAV) has only recently emerged in virulent form, has been able to do so as a result of changing socio-economic factors in Africa and may be followed by equivalent conversions to virulence of other relatively harmless viruses. More optimistically, the question becomes: can one learn anything from the origin of the virus that would help to contain the disease?

Geographically, the finger of suspicion points at Central Africa, possibly Zaire, as the location from which the virus has spread. The data, however, are sketchy and dependent on what historical and contemporary sera samples are available for analysis, and to whom. From one of the most extensive surveys so far, G.de Thé of the CNRS, Lyon, provisionally concluded that the virus emerged in Kenya only after 1970, that there are still very puzzling differences between adjacent countries, and that there may be evidence of change of viral form in some comparative data.

The evidence of change comes from the comparison of two tests, one of which (an enzyme-linked immunosorbent assay) is less sensitive to change than the other ("Western blotting" of proteins). That the current virus is very prone to change is clear. The sequences of viruses that came directly or indirectly from patients in New York in 1982-83 differ by only a few per cent, whereas the sequences of a virus from a Haitian taken in the same period and one from a resident of San Francisco isolated in 1984 show considerable differences Most variation is in the mid-portion of the gene that encodes the envelope protein of the virus. Up to 25 per cent variation is recorded there, according to W. Haseltine of Harvard Medical School.

By definition, however, all of these isolates and the other hundred or so whose variation is fully documented in only a few cases, are from AIDS patients. All, therefore, have caused immunodeficiency, and no correlation has emerged between variation in viral structure and the precise manifestations of the immunodeficiency syndromes. The pressing question is whether such a correlation can be found and, in particular, whether the African population will yield variants that are less prone to cause AIDS and from which the "American" variants are descended. In other words, do viral differences account for the fact that AIDS in Central Africa seems to be equally distributed between the sexes and transmitted by heterosexual activities rather than largely by homosexual practice and blood or its products? Or are these differences only a temporary reflection of the initial entry of the virus into the industrialized nations through the homosexual community? The signs are more that the latter is the case.

Now the focus of attention has shifted to the African green monkey. Most of some recently collected specimens from the wild in Zaire contain serum proteins characteristic of HTLV-III/LAV and yet are healthy, according to M. Essex from Harvard School of Public Health. A comparative study of the monkey and human virus together with that which caused an outbreak of AIDS-like disease in a captive colony of Macaque monkeys in the New England Primate Center may help to clarify the origin and virulence of HTLV-III/LAV and suggest approaches to vaccination or therapy.

A separate reason for delving deeply into variants is to discover whether sequence changes are responsible for some of the human pathologies other than AIDS with which HTLV-III/LAV is coming to be associated. R. Gallo from the National Cancer Institute in Bethesda, Maryland, pointed in particular to an association with brain abnormalities in children without immune deficiency; evidence exists for the presence of replicating virus in the human brain, particularly in glial cells. Such evidence tends to strengthen the claims of both Gallo and S. Wain-Hobson, of the Institut Pasteur in Paris, that HTLV-III/LAV is related to the lentiviruses, of which the prototype is visna virus, which causes a slowly progressive demyelinating disease of the central nervous system of sheep. Gallo also tentatively suggested a new pathological involvement of the virus that would dispense with the first word of idiopathic thrombocytopaenic purpura.

While AIDS is a growing concern in the industrialized nations, African priorities lie elsewhere. In Senegal, for example, either there is no AIDS or it has not yet been recognized, whereas many die from a liver cancer caused in part by hepatitis B virus. In Africa generally this, and cervical cancer are major types of cancer. A third virus-associated cancer in Africa is Burkitt's lymphoma, an infrequent disease but responsible for many childhood tumours and causally linked to the Epstein-Barr virus.

None of these viruses causes cancer without contributory factors, of which immunodeficiency is the most interesting to AIDS researchers. For Burkitt's lymphoma, immonodeficiency — in the form of lost of T-lymphocyte control of Epstein-Barr virus infected B cells — is induced by malaria, as shown by H. Whittle of the MRC Laboratories, The Gambia. And a mini-epidemic of Burkitt's lymphoma in US AIDS patients suggests that any form of immunosuppression is liable to activate the latent virus.

Hopes, however thin, are pinned on the development of a vaccine against HTLV-III/LAV. For the hepatitis B virus, vaccines are already in trial but for the Epstein-Barr virus the first glimpse of a vaccine was provided in Senegal by M.A. Epstein of the University of Bristol. The vaccine is composed of one of the major proteins of the virus and protects cotton-top tamarins against cancers induced by the virus. The tamarin disease does not altogether resemble the human disease and the frequency of Burkitt's lymphoma may never warrant mass vaccination in terms of cost. In Asian countries where the virus is a part cause of nasopharyngeal cancer, vaccination may be more realistic. Epstein foresees an initial trial of the vaccine against mononucleosis, the relatively mild result of infection by the virus after childhood.

The AIDS researchers who dropped in on Senegal need African collaborators in order, at the least, to carry out extensive trans-African surveys of AIDS, its virus and its origins. The Africans leaving Senegal knew at least that they had increased the awareness of the diseases and priorities in Africa among those who could provide help.

Peter Newmark

Isotope geochemistry

Contamination or source-region heterogeneity?

from Alex Halliday

OVER the past thirty years considerable effort has been invested in using the isotope compositions of certain elements (principally Sr, Pb, Nd and O) to reveal information about the chemistry and history of the source regions of magmas. There are two causes of variation in isotope ratios — radioactive decay (for example, the production of ^{87}Sr from ^{87}Rb) and mass-dependent isotope fractionation during reactions. In the first case, the isotope compositions tell us about the chemical history (that is, the age and parent/daughter elemental ratios) of the source. In the second case we can, in addition, learn about some specific processes that operated in the magma itself. Such data have been fundamental in solving major petrological problems such as the origin of granites and basalts. This has led to a relatively detailed knowledge of the chemical structure and evolution of the Earth's mantle and of the growth of the continental crust.

But the case is not always as clear cut. There is still debate over the interpretation of the isotopic characteristics of rocks believed to have formed in the mantle but to have risen through the continental crust. The argument centres on the relative roles played by contamination by the continental crust and inheritance of features from the sub-continental mantle. The problem is fundamental to the origin of igneous rocks and is made worse by the range and complexity of potential contamination mechanisms, for example, by fluids or partial melts, which produce non-diagnostic effects. One school of thought discounts crustal contamination on the basis of banal assumptions about the probable effects, whereas those from the other school simply ignore the possibility that anomalous mantle is important. Attempts to resolve these views have often resorted to lengthy convoluted arguments.

Fortunately there are some studies which have shed light on this confusion and have provided clear evidence for both open (contaminated) system behaviour and the existence of anomalous mantle. The recent work of Cortini and van Calsteren[1] is refreshing in that they have studied the genesis of lavas from southern Italy by determining the Pb isotope composition in separated phenocrysts (thought to be crystals precipitated from the magma) as well as in whole rocks. The observation of a systematic isotope disequilibrium led to the conclusion that some open system process has operated, which clearly could not have been demonstrated so unambigously if the authors had simply analysed the whole rock samples. Remarkably few such detailed dissections of lavas have been performed previously, although studies of nodule suites[2,3] have provided incontrovertible evidence for anomalous sub-continental mantle and others have proved the presence of crustal components in plutonic rocks[4,5]. Having said this, studying minerals separated from volcanic rocks for signs of open systems behaviour is not new[6-8], and the evidence acquired for significant isotope disequilibrium has been ascribed to a number of possible causes.

These kinds of studies highlight two important features that could provide the key to understanding the genesis of young volcanic suites. First, detailed studies that include mineral separation and analysis of individual mineral grains and glass, although tedious, are of immense potential value in providing clear evidence of open system processes. One might further envisage that with the development of ion-probe techniques detailed spatial resolution of trace-element concentration and oxygen-isotope composition will also be an exceedingly powerful way to proceed. Second, much more information on petrogenetic processes can be obtained by using various isotope techniques to study the samples. The elements in silicate systems vary in their mass-transfer response to different conditions and processes. Hence, it is now simply inadequate to study contamination with a single isotope method. It is also a less efficient use of resources to use different samples when using different techniques. Combined isotope studies optimize information with which to define uniquely a signature for a component or process. As there are many igneous provinces for which the crustal contamination versus enriched mantle debate is still unsettled, it is to be hoped that fresh approaches will provide further rigorous testing for the two hypotheses. □

Tumour immunology

Molecular basis of tumour spread

from Ian R. Hart

METASTASIS, the spread of tumours throughout the body, is a process of obvious clinical significance. Despite the fundamental importance of the phenomenon, relatively little is known about the molecular and cellular mechanisms of its regulation and control. One way in which disseminating malignant cells may evade host defences is suggested in a report on page 301 of this issue, where transfection of neoplastic murine cells with *H-2* genes is accompanied by nullification of their metastatic capacity[1].

Major histocompatibility complex (MHC) class 1 antigens (termed H-2 K,D and L in mice) are distributed widely on nearly all cell types and play an obligatory role in immunoregulation; cytotoxic T lymphocytes only recognize 'foreign' antigens when they are associated with these class I molecules. Immune regulation of tumour growth and development, then, is not solely a consequence of tumour-cell antigens but also depends on MHC class I antigen expression, as demonstrated experimentally in recent studies using DNA transfection techniques[2,3]. If solid tumour growth can be affected so profoundly by class I antigen expression, how much more likely are metastasizing cells, travelling through the body singly or in small clumps, to be affected by a similarly regulated immune response? The answer, provided by Hammerling and colleagues[1], seems to be that such effects are just as dramatic.

Two clones from the murine T10 sarcoma, one metastatic and one non-metastatic but both lacking expression of H-2 molecules encoded by the K-end of the H-2 complex, were transfected with $H\text{-}2K^b$ or $H\text{-}2K^k$ genes. Expression of these H-2K antigens in the metastatic clone was found to be associated with a profound decrease in metastatic capacity as determined in immunocompetent recipient mice. Metastatic capacity in immunologically depleted animals remained unimpaired, thus demonstrating the central involvement of the immune response in this phenomenon.

Limitation of metastatic spread by an immune response regulated through MHC class 1 antigens not only offers hope for potential therapeutic application (interferons, for example, induce a marked increase in the surface expression of these molecules), but also suggests that an inverse relationship exists between malignancy and expression of MHC class 1 molecules[4].

This phenomenon may account for the marked heterogeneity that exists for the metastatic phenotype in tumour cell populations[5]. Some findings are consistent

with the existence of such an association; melanoma metastases may lack HLA-DR antigen expression[6], and malignant mammary carcinomas may exhibit a deficiency in HLA class 1 antigen expression[7,8]. Certainly, future studies will test the generality of this association, although unfettered enthusiasm for such an all-encompassing theory on how tumour dissemination occurs must even now be tempered by the knowledge that suppression of MHC class 1 gene expression is not a universal characteristic of malignant tumours, nor are specific immune mechanisms the only host defence systems capable of modulating metastatic spread[9]. Indeed, increases in MHC class 1 gene expression may also be associated with metastatic capacity. Earlier studies have shown that expression of the D^k molecule may contribute to the metastatic behaviour of tumour cells[10], and a similar association between metastatic activity and expression of a gene homologous to MHC class 1 antigens has been established in another murine tumour system[11].

Recently the metastatic phenotype has been expressed by Ha-*ras* oncogene-transformed NIH 3T3 mouse fibroblast cells following transfection with genomic DNA isolated from a human metastatic tumour[12]. Acquisition of metastatic capacity correlates with the presence of discrete human DNA fragments, possibly representing a novel gene. Metastatic spread of the Ha-*ras*-transformed cells occurred in immunoincompetent (irradiated) nude mice but not in immunocompetent, histocompatible mice; the metastatic transfectants are capable of metastasizing both in immune depleted and in immunocompetent mice. Presumably the transfected gene confers some protection against the immune system and an attractive possibility is that this gene could turn out to be homologous to the putatively suppressogenic *H-2D*[1,11].

Unfortunately, such attempts to seek a single unifying explanation for the regulation of metastatic spread are probably oversimplifications; the complex multifactorial nature of the phenomenon suggests that answers obtained are likely to be as varied as the models used to address the questions. The true significance of Hammerling *et al.*'s report[1], along with other recent studies, may lie in the fact that these investigations represent the first applications of the techniques of modern molecular biology, such as gene transfer, to the central problem of clinical cancer and to a still major conundrum of tumour biology. □

It is still unknown whether the recent findings are relevant to scrapie, illustrated here by a Cheviot sheep rubbing compulsively against a fence (photo courtesy of AFRC and MRC Neuropathogenesis Unit, Edinburgh, UK).

Scrapie

Persistently puzzling prions

from Tim Harris

MANY features of scrapie — a degenerative neurological disease of sheep and goats — including pathological similarities to the human degenerative diseases kuru and Creutzfeld-Jacob disease, suggest that it is caused by a 'slow' virus. The inability to find any typical virus particle consisting of nucleic acid and protein, however, coupled with the unusual resistance of infectivity to agents that normally inactivate nucleic acids, has led to some radical thinking about the nature of the scrapie agent. It has been proposed, principally by Stanley Prusiner and his colleagues[1,2], that a new type of proteinaceous infectious particle or 'prion' is involved in scrapie infection (for review, see ref.3). Two recent studies[4,5], one reported on page 331 of this issue[4], have now begun to produce molecular evidence that call this claim into question.

The evidence for the existence of prions stems largely from the fact that scrapie infectivity is proteinase sensitive, and that rod-shaped particles resembling amyloid fibrils are observed to co-migrate with infectivity in sucrose density gradients. SDS polyacrylamide gel electrophoresis of the proteins in this fraction (where infectivity is considerably enriched with respect to protein) has revealed a single polypeptide, PrP (prion protein) 27-30, of relative molecular mass 30,000; no nucleic acid has been found to be associated with it. Several models for the mechanism of prion replication have been put forward[6], the most heretical of which are that the protein is back-translated into nucleic acid (as yet achieved only by computer), or that PrP is a template for its own synthesis.

Recently, PrP has been purified and its partial amino-acid sequence obtained. The availability of this sequence for the design of oligonucleotide probes means that, if there is a messenger RNA for PrP, it would be only a matter of time before the isolation of complementary DNA clones. Given the degree of interest in the elusive scrapie agent, it is not surprising that this has happened sooner rather than later.

These molecular studies[4,5] present the cloning and sequencing of the mRNA for PrP 27-30 and show it to be the product of a single cellular gene. In addition, specific mRNA for PrP 27-30 is found in normal as well as in infected tissue. Can molecular biologists now heave a collective sigh of relief that the central dogma is still intact and that proteins do not self-replicate? For the time being the answer is probably yes, because unless the protein in infected tissue is subtly different to that in normal tissue (as has been found for certain cellular oncogenes), then it seems unlikely that PrP 27-30 is anything other than a normal cellular glycoprotein, the synthesis or degradation of which may be altered as a result of scrapie infection.

Nevertheless, the clarification of the origin of PrP 27-30 still does not explain the nature of the scrapie agent. In a negative way it does lend tacit support to the more conventional argument for a small scrapie-specific nucleic acid, suggested by the existence of different strains of the agent[7]. Whether this nucleic acid is contained in a small virus particle with a low particle-to-infectivity ratio, or is viroid-like and not encapsidated is not clear. But what is clear, now that PrP has been shown to be the product of a cellular gene, is that the hunt for the real scrapie agent is back with a vengeance. □

Heavy-ion physics

Giant nucleus at Darmstadt?

from Joshua Silver

WHEN an energetic very heavy ion passes close to the nucleus of a heavy atom in a solid target, positrons may be spontaneously produced within the electron shells of the atom. Recently, researchers at the heavy-ion facility at GSI Darmstadt, West Germany, have been examining this phenomenon. One particularly exciting possibility emerging from these experiments is that extremely heavy nuclei, with atomic number and mass of about 180 and 470 respectively, might be produced in heavy-ion scatterings. Although such products would be short lived, they might open up the study of atoms with unprecedented properties.

Consider an atom of variable nuclear charge Z. As Z increases, the binding energy of the innermost electrons, $E(1s)$, becomes more negative. Forgetting for a moment the fact that there are no atoms with $Z > 109$, we may calculate $E(1s)$ using the Dirac equation with a Coulomb potential for arbitrary Z. It is found[1-3] that for a non-zero nuclear charge radius, $E(1s)$ falls below $-2m_ec^2$ for $Z \geqslant 173$, where m_e is the rest mass of the electron and c is the velocity of light. When $E(1s)$ is less than $-2m_ec^2$, the discrete bound electron state becomes degenerate in energy with a three-particle continuum state, consisting of two bound electrons plus an outgoing positron wave.

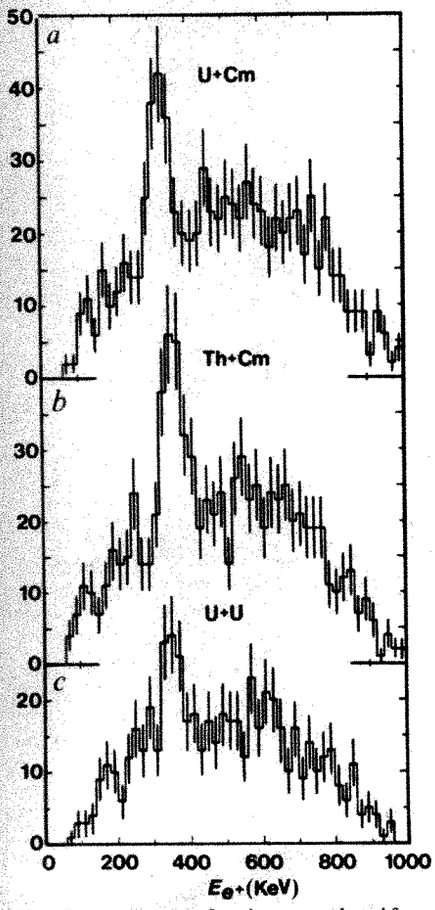

Fig. 1 Energy spectra of positrons produced from collisions of *a*, ^{238}U (Z = 92) on ^{238}Cm (Z = 96); b, ^{232}Th (Z = 90) on ^{248}CM (Z = 96); *c*, ^{238}U (Z = 92). Bombarding energies are ~ 6 MeV A^{-1}, and the angular range (of the order of 100) of the ions scattered in coincidence with the detected positrons gives the most pronounced ~ 300 keV positron 'line' in each case (from ref. 7).

It was first suggested by Gershtein and Zel'dovich[1] that this 'autoionizing' mode of spontaneous positron production might be observable in heavy-ion collisions. The idea is that for a sufficiently close collision of two very heavy ions, it is possible for the 'innermost' 1s electrons of the projectile or target atom to experience a Coulomb field similar to that from a nucleus with $Z \geqslant 173$, so long as $Z_1 + Z_2 \geqslant 173$, where Z_1 is the atomic number of the projectile ion and Z_2 the atomic number of the target atom[4]. This approach, however, suffers from a weakness — in the words of Müller[5], the method is "both a curse and a gift"; the rapid time variation of the Coulomb field during the collision leads to ionization of 1s electrons from the collision partners, thereby creating vacancies. This is the "gift", in that spontaneous production of positrons is suppressed by the Pauli exclusion principle if the 1s levels are full. However, the time variation of the Coulomb field is also responsible for induced positron production which can mask the spontaneous process. Calculation of the relative probabilities of the spontaneous and induced processes is difficult; for completely elastic scattering along Rutherford trajectories the two processes cannot be distinguished in principle. There is also a contribution to the total positron production from nuclear mechanisms.

Three experimental groups have used the heavy-ion accelerator at GSI Darmstadt for several years to search for spontaneously produced positrons. In the past two years, these groups have observed a new phenomenon that is difficult to explain[6-8]. For coincident observation of positrons with particles scattered in well-defined angular ranges, and at well-defined ion-beam energies in a narrow interval around the Coulomb barrier, the energy spectra of the positrons produced during a collision can show a distinct 'line' at around 300 keV. Typical spectra are shown in Fig. 1. The width of this line may be used to infer a duration for the collision, simply from Heisenberg's energy-time uncertainty relation. The smallest widths observed so far (about 60 keV) translate into a characteristic time for the positron production process of the order of 10^{-19} seconds. Now it is also possible, from the dynamics of the collision, to estimate the time during which the collision partners are sufficiently close together for the transient 'united atom' Coulomb

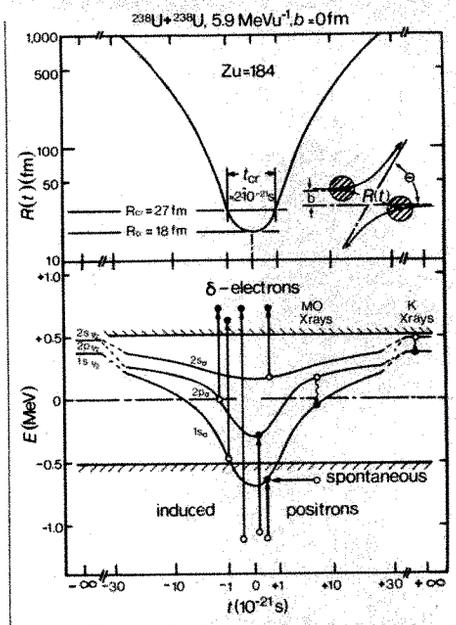

Fig. 2. Electron-binding energies, t, for the three most bound states (top) and the internuclear separation, $R(t)$, for two ^{238}U nuclei as a function of time (bottom) for a collision between a stationary target nucleus and a projectile with energy 1·40 GeV, with impact parameter b = 0. Note that $E(1s)$ is $< -2m_ec^2$ for a time of the order of 2×10^{-21} s for this collision (from ref. 10).

field to be large enough to give rise to spontaneous positron emission. For the typical system ^{238}U + ^{238}U at a beam energy of 1·40 GeV and a head-on collision, this time is ~ 10^{-21} seconds, two orders less than the duration inferred from the width of the positron line (Fig. 2). What is going on?

One possible explanation is the formation, during the collision, of a transient 'giant di-nuclear system' or 'giant nuclear molecule' which lasts for at least 10^{-19} seconds. At present, it is not clear that this explanation is correct or complete, and one problem that is not easily explained is that the most well-defined positron lines are all at an energy of about 300 keV. Nonetheless, the possible creation of an (albeit transient) nuclear system with an atomic mass of about 470 and an atomic number of around 180 is most exciting and has triggered more experimental and theoretical work, in an attempt to understand what is really happening. With the increasing availability of heavy-ion beams of suitable energy it is likely that this phenomenon will soon be better understood. □

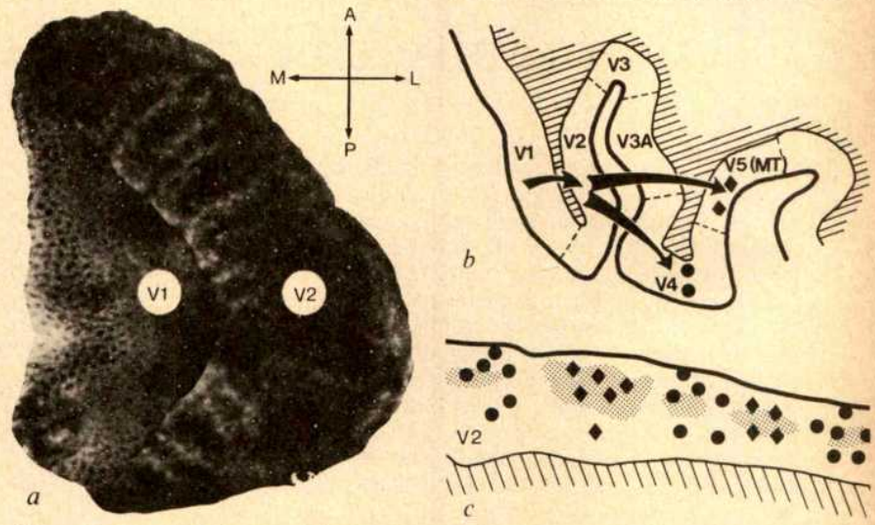
Visual cortex

Stars and stripes present the colours

from Ian Thompson

THE primate prestriate cortex contains several visual areas, each with its own representation of the visual field and a particular set of receptive-field properties. Their major input arises from striate cortex (V1, sometimes termed area 17) either directly, or indirectly via the projection from V1 to V2. How, then, is the observed diversity of function generated by the input from V1 and V2? Does it depend on specific intra-cortical processing within each area or does it arise because each area receives a functionally specific input? Two papers on pages 322[1] and 325[2] of this issue and one in the press[3] provide complementary information on how anatomical and functional inhomogeneities within one visual area (V2) are related to the neuronal projection pattern between V2 and areas in the prestriate cortex concerned with colour (V4) and movement (termed V5 or MT).

Neurones in V4 and in V5 (MT) display marked differences in some of their stimulus specificities. In V5 (MT), they are selective for the speed and direction of a moving object, irrespective of its colour[4-6]. The responses of cells in V4 are much more dependent on the spectral properties of the stimulus[5,6] and may display some form of colour constancy[7]. How do these differences arise?



One possibility is that there are separate populations of neurones in V2 projecting to the two areas. Using retrogradely transported tracers injected into V4 or V5 (MT), Shipp and Zeki[1] have demonstrated bands of labelled neurones in V2 that lie orthogonally to the V1/V2 border. Stripes with this orientation in V2 are also seen with another neuroanatomical method, staining for the distribution of the enzyme cytochrome oxidase (part *a* of figure), but Shipp and Zeki note that the spacing of the bands of labelled neurones is twice that of the cytochrome oxidase stripes. In favourable sections, especially from infragranular layers of macaque cortex or from squirrel monkeys, the dark cytochrome oxidase-positive stripes appear alternately thick and thin, separated by light (cytochrome oxidase-negative) interstripe zones. Where identification of thick and thin stripes was possible, Shipp and Zeki report that neurones labelled after a V5 injection coincide with thick cytochrome oxidase stripes, whereas cells labelled from V4 are associated with thin stripes or, occasionally, with the interstripe region (figure *b*,*c*). They conclude that the output neurones from V2 to V4 or to V5 (MT) are clustered into alternating bands. This conclusion is elegantly confirmed by DeYoe and Van Essen[3] who use two tracers that fluoresce at different wavelengths, one injected into V4 and the other into MT (V5). In V2, adjacent bands are labelled with different tracers and no cells are obviously labelled with both.

Given the anatomical heterogenity in V2, is there any corresponding grouping in the physiological properties of its neurones, as suggested by an earlier 2-deoxyglucose study[8]? Using electrophysiological techniques, all three groups[1-3] describe clustering of receptive field characteristics such as colour, orientation and directionality. Unfortunately, the reports differ in the details of the relation between the clusters and the stripes. One contributory problem seems to be reliable identification of thick and thin stripes. DeYoe and Van Essen[3] minimize the problem by combining quantitative electrophysiology, fluorescent tracers and cytochrome oxidase staining. They describe an association of colour selective units with the distribution of cells projecting to V4, which they find can arise from both the thin stripes and interstripes.

The suggested association of colour cells with thin cytochrome oxidase stripes in V2 is interesting because these stripes are thought to be the termination site of the projection from the cytochrome oxidase blobs in V1[9]. Having found previously that V1 blobs were associated with non-oriented double-opponent colour cells[9], Hubel and Livingstone[2] now describe a receptive-field type, associated with thin stripes in V2, which they suggest represents an hierarchical elaboration of the V1 double-opponent cell. The new type is also non-oriented and double-opponent but shows spatial summation over a region smaller than that of its receptive field. An optimally sized spot is thus equally effective in several positions in the receptive field, a characteristic of complex cells. Hubel and Livingstone postulate that this type of receptive field represents a comparable transformation with that occurring between oriented simple and complex cells. The 'non-complex' double-opponent cells are first seen in V1, possibly reflecting a convergence of afferents from the lateral geniculate nucleus in the thalamus, analogous to that generating oriented simple cells[9].

The existence of distinct anatomical pathways within V2 projecting to V4 or to MT (and possibly also to other areas[3]) raises several interesting questions. How is the visual image represented in each pathway? Does each contain a separate map or is the scatter in the topography of V2 sufficient to ensure adequate representation in each projection? Magnification-factor data would be welcome. The anatomical sub-regions are large with the repeat distance from thin stripe to thin stripe between 2.5 and 5 mm. Thus, finer-scale functional representations are possible in the sub-regions, indications of which can be seen in the 2-deoxyglucose results[8]. In fact, it would be surprising if all neurones within a sub-region were functionally identical. Quantitative investigation of distributions of response properties should generate a clearer picture of visual analyses performed in the different visual regions.

Finally, what developmental mechanisms generate the anatomical and functional diversity? The pattern of retrogradely labelled cells in V2[1,3] is reminiscent of the banding of afferent terminals seen when two projections map onto the same neural sheet, for example, ocular dominance columns in striate cortex or in the tectum of

Schematic summary of connectivity patterns within pre-striate cortex taken from refs 1-3. Photomicrograph *a* shows the distribution of cytochrome oxidase staining in a tangential section through V1 (area 17) and V2 (area 18) of squirrel-monkey cortex. A characteristic neuronal connectivity pattern exists between the spots in V1 and the stripes in V2. *b*, V2 projects both to V4 and to V5 (MT) with the cells of origin of both projections clearly segregated into alternating bands in V2 (*c*), depicted by the circle and diamond symbols. An association between the cells of origin and the thick and thin cytochrome oxidase stripes (stippling) is also described in *c*.

three-eyed frogs[10]. Are the two patterns analogous, providing a solution to the problem of accommodating two maps in one structure? If separate maps do occur in one area, then there is a problem with the idea of a one-to-one relationship of function to cortical area. Pursuing the ocular-dominance column analogy, do the projection bands develop from an initially uniform distribution? Recent results from the cat are suggestive — Price and Blakemore have found that cells projecting from area 17 to area 18 initially have a continuous distribution that becomes patchy during development[11]. □

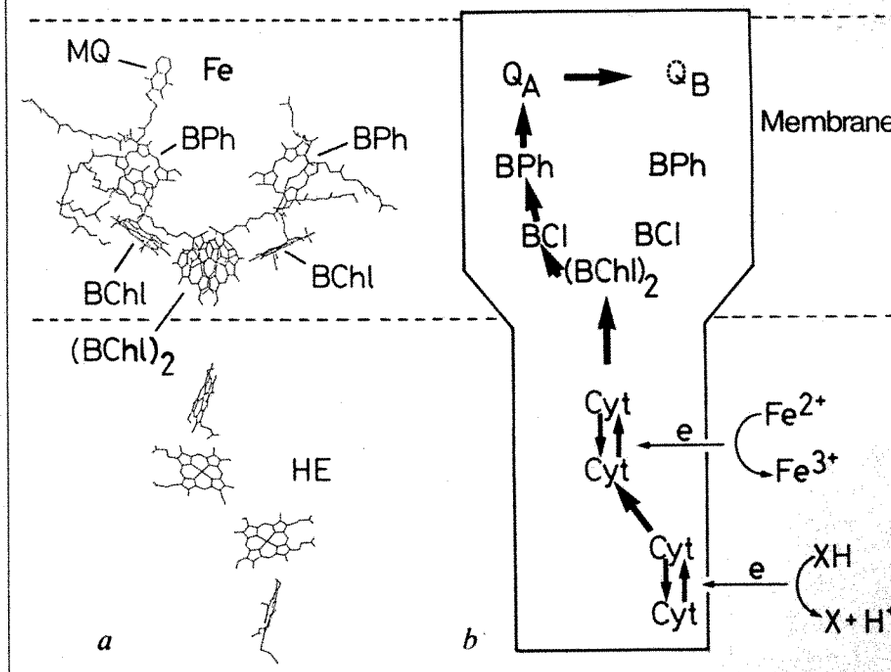
Protein crystallography

A reaction centre elucidated

from Jim Barber

PHOTOSYNTHETIC organisms contain specialized proteins — reaction centres — that function to convert the energy of an absorbed photon into the chemical potential necessary to synthesize organic molecules. In all classes of photosynthetic organisms the reaction centre is embedded in a membrane matrix with closely associated pigmented proteins acting as light collection systems. Photons absorbed by these light-collecting proteins cause excitations in the pigments, which are efficiently transferred to the reaction centre. On arrival at the centre the excitation causes a rapid charge separation, the primary step in the conversion of light energy to chemical potential.



This charge-separation process has some remarkable features which have not yet been reproduced in artificial photochemical systems. The most striking features are the speed of the process, which occurs within a few picoseconds, and its very high efficiency. Although some elegant experimental and theoretical studies have attempted to elucidate the mechanisms by which reaction centres bring about energy conversion, progress had been hampered by the unkown molecular organization of components of the protein. Such restrictions have now been lifted because of the success of a group working in Munich, who have crystallized the isolated reaction centre of *Rhodopseudomonas viridis*.

R. viridis is a gram-negative non-sulphur photosynthetic bacterium first identified only twenty years ago. It contains bacteriochlorophyll-*b* (BChl-*b*) as well as several different carotenoids. The bulk of these pigments make up the light-collecting system but a small percentage of the BChl-*b* and carotenoids is found in the reaction centre protein. The precise composition of the *R. viridis* reaction centre was not known until it was isolated as a complete functional entity by J. Thornber *et al.* (*Biochim. biophys. Acta* **172**, 351; 1969). It was soon established that this reaction centre contained four BChl-*b* molecules, two of which form a 'special pair'. These are able to undergo photo-oxidation, detected as an absorption decrease at 960 nm (P960). The isolated protein also contains two molecules of bacteriopheophytin-*b* (BPhe-*b*), two quinone molecules (menaquinone and ubiquinone), a non-haem iron atom and four cytochrome *c* molecules, two with absorption peaks at 553 nm (C553) and two at 558 nm (C558). Gel electrophoresis indicated that the isolated protein is a complex consisting of four different polypeptides of relative molecular mass (M_r) 38,000, 33,000, 28,000 and 24,000. The last three polypeptides are analagous to those in the reaction centres of other purple bacteria and have been designated H (heavy), M (medium) and L (light) subunits, respectively. The M_r 38,000 component is only found in the *R. viridis* reaction centre and is the polypeptide that binds C553 and C558.

Since the study of Thornber *et al.*, the composition and spectroscopic properties of the *R. viridis* reaction centre have been established using a range of techniques including electron spin resonance, nuclear magnetic resonance, picosecond absorption spectroscopy, fluorescence transients and linear and circular dichroism. As a consquence of these investigations new theories of electron tunnelling and charge stabilization have emerged and structural models have been postulated.

Three years ago, H.Michel successfully obtained crystals of the *R. viridis* reaction centre suitable for high resolution X-ray diffraction analysis which maintained photochemical activity (*J. molec. Biol.* **158**, 567; 1982). In collaboration with J. Deisenhofer, D. Epp, K. Miki and R. Huber, he has now been able to determine the structure of these crystals to a 3 Å level of resolution (*J. molec. Biol.* **180**, 385; 1984). The structural details confirm predictions from spectroscopic measurements as well as revealing some unusual features, still of unknown meaning.

According to X-ray analysis, the protein

Models for the reaction centre of *Rhodopseudomonas viridis*. *a*, Relative positioning and orientation of the prosthetic groups of the reaction centre showing the special pair $(BChl)_2$, two monomeric bacteriochlorophyll-*b* (BChl), two monomeric bacteriopheophytin-*b* (BPh), one non-haem iron (Fe), one menaquinone (MQ) and the four cytochrome haems (HE). The central local symmetry axis runs vertically in the plane of the picture. Broken lines suggest the position of the membrane whose plane is assumed to be orientated perpendicular to the central local symmetry axis. (Modified from Deisenhofer *et al. J. molec. Biol.* **180**, 385; 1984.) *b*, Schematic drawing of the reaction-centre complex showing electron-transport pathways. Q_A, menaquinon; Q_B, ubiquinon, which is lost during cystallization. The special pair $(BChl)_2$, BChl, BPh and Q_A are located in a cylindrical part of the reaction centre. Bound cytochromes (C553 and C558) occur as high potential haems, assumed to be reduced to soluble cytochrome c_2, ($Fe^{2+} \rightarrow Fe^{3+}$) and in closest proximity to the special pair, as low potential haems, which can presumably be reduced by organic acids (XH).

complex has an elongated shape with three clearly distinguishable regions. The central portion consists of the L and M polypeptides and is a 50-Å long cylinder with an elliptical cross-section of diameters between 50 and 70 Å. To each flat face of the cylinder, a globular subunit is attached so that the longest dimension of the entire reaction-centre complex is about 140 Å. One of the globular subunits contains the four haem groups of cytochromes C553 and C558, and the central cylinder is the site for the four BChl-*b*, two BPh-*b* and a high electron-density peak from a non-haem iron atom. The other globular structure is presumably the H-subunit, known not to be directly involved in the photoactivity of the reaction centre.

Although the Munich group has not fully elucidated the complete polypeptide structure, it has obtained details of the spatial relationships between various components involved in charge stabilization (see figure). A prominent feature is that the BChl-*b* and BPh-*b* molecules are arranged with an approximate 2-fold rotational symmetry. The rotation axis runs through (or nearly through) the non-haem iron atom and through two closely associated BChl-*b* molecules, whose pyrrole rings are stacked on each other. These two BChl-*b* molecules are the 'special pair' corresponding to P960; the X-ray diffraction data indicate that a linkage exists between the magnesium atom of one tetrapyrrole head and the acetyl group of ring 1 of the other, a conclusion which invalidates an earlier suggestion that water was involved in bridging. The average distance between the atoms of the tetrapyrrole heads is 3 Å with a Mg-Mg distance of 7 Å, and the angle between the ring planes is about 15°. Interestingly, the other two BChl-*b* molecules are symmetrically spaced from the special pair at a Mg-Mg distance of about 13 Å and an angle of 70° between the planes of the tetrapyrrole head groups. Both the monomeric BChl-*b* molecules contact BPh-*b*, with a spacing between ring centres of approximately 11 Å and a 64° angle between ring planes. Although all the tetrapyrrole rings are on the same 2-fold rotational axis, their phytyl side chains are not.

The non-haem iron atom is positioned on the 2-fold rotation axis and is linked to at least three histidine residues, one of which has an electron density close to it that is indicative of menaquinone (Q_A). The iron-quinone distance is approximately 7 Å and, significantly, in the symmetry-equivalent position to the quinone ring related by the 2-fold axis, is an empty 'pocket' in the protein. Michel and collaborators suggest that this empty pocket is the ubiquinone binding site termed Q_B. Although the haem groups in the cytochrome subunits do have a symmetrical arrangement, they are not positioned on the 2-fold rotational axis relating the BChl-*b* and BPh-*b* molecules. Only the haem closest to the special pair lies on this symmetry axis with an Fe-Mg distance of about 21 Å. Thus, it may be this cytochrome which directly reduces the photo-oxidized special pair ($P960^+$).

From the diffraction analysis it is clear that the L and M subunits form the central cylinder, which consists of five transmembrane helices, each being related by the 2-fold rotational axis. Because of this, both subunits are equally involved in forming the special pair and the non-haem iron-quinone complex. Both the cytochrome and H-subunits also contain helices.

In many ways the structure determined by X-ray crystallography has supported several concepts derived from spectroscopy. Clearly the organization of the components confirms that primary charge separation involves the following electron transfer sequence:

$$(\text{BChl-}b)_2 \rightarrow \text{BChl-}b \rightarrow \text{BPh} \rightarrow \text{menaquinone } (Q_A)$$

with $(\text{BChl-}b)^+_2$ being reduced by cytochrome *c* while menaquinone passes its electron to a ubiquinone (Q_B) molecule normally bound in the vacant pocket. The structural model also supports the chromaphore orientation data obtained from linear and circular dichroism. The puzzling, as yet unaccountable, feature is the symmetrical arrangement of the two monomeric forms of BChl-*b* and BPh-*b*, which suggests two possible electron transfer pathways. However, evidence suggests that only one pathway is preferred so that an electron is always passed to Q_A, the bound menaquinone, before going to ubiquinone (Q_B). It seems, therefore, that one BChl-*b* and one BPh-*b* molecule are not normally involved in the process of charge separation.

It could be argued that the reaction centre of *R. viridis* has evolved from a more primitive reaction centre consisting of one subunit only, and that the dimerization giving rise to the L and M polypeptides facilitated the formation of the special pair and the opportunity for improving charge stabilization by allowing the Q_A to Q_B electron transfer to occur. The precise factors which have given rise to the preferred pathways will become clear as the detailed structure of the polypeptide chains are determined from the electron-density map. Moreover, the role of the H-subunit should become more obvious as Deisenhofer and colleagues continue to elucidate the total structure of the protein complex.

In any event, it is probable that the molecular details of the *R. viridis* reaction centre will not only allow the theoreticians to understand how the high efficiency of energy conversion is attained in this specific protein, but will also act as a model for the reaction centres of other organisms. In fact the *R. viridis* reaction centre is structurally and functionally similar to the reaction centres of several purple non-sulphur bacteria. Even more exciting is that the knowledge gained from these studies will form an important basis for elucidating the molecular basis of the mechanism of water splitting by green plants and algae, because these reactions occur at a reaction centre (photosystem two) having features similar to those of the purple bacteria. We can also look forward to a future where X-ray crystallography will unravel the details of a wide range of membrane processes at the resolution of atomic distances. □

Palaeoclimatology

Records of past continental climates in deep-sea sediments

from Joseph M. Prospero

EVERYONE talks about palaeoclimate, but no one seems to know much about it. This is especially true for continental climates where the often subtle evidence of past weather conditions is easily obliterated by subsequent events. Even when evidence is found, in many cases it is not possible to date the events. Ocean scientists are more fortunate because a good chronological record of past oceanic conditions (such as water temperature) can often be read in the neatly ordered layers of deep-sea sediments that span many millions of years. Recently, Rea *et al.* (*Science* **227**, 721; 1985) have shown that these sediments also contain information about past continental climates. Their conclusions about atmospheric circulation over the past 70 million years not only challenge conventional views on palaeoclimates, but also provide a test for computer climate models.

Rea *et al.* analysed the windborne (aeolian) mineral dust components in four North Pacific sediment core sections spanning the past 70 Myr and found major changes in particle size, concentration and the mass accumulation rate. They suggest that the accumulation rate data are indicative of the availability of material in the source area and should be related in some way to climate, especially to aridity. The mineralogy of the aeolian grains also provides clues to the climate of the source region and, most importantly, the size distribution can be used to infer the speed of the transporting winds.

On the basis of their assumptions, the authors conclude that the atmospheric circulation was quite vigorous during the late Cretaceous and Palaeocene, but moderated

sharply in the early Eocene (50 Myr ago) before commencing a steady increase that culminated in a maximum associated with the Pliocene-Pleistocene glaciations of 4-2 Myr ago. The most surprising outcome of this work is the implication that circulation during the late Cretaceous was as vigorous as that in the Palaeocene. This is contrary to the long-held belief of geologists and palaeoclimatologists that the Cretaceous was a period of moderate climate and relatively weak circulation, but is supported by recent computer models.

Data such as that of Rea *et al.* are important as relatively rigorous tests of long-term climate models, which otherwise would be little more than interesting intellectual exercises. It is therefore necessary to scrutinize the underlying assumptions of such studies. The most critical assumption is that which relates aeolian particle sizes to the speed of the transporting wind. Rea *et al.* assume that, for any one wind speed, there is a characteristic particle-size spectrum of dust grains which are in 'equilibrium' with the wind, where the "lifting effect of the inherent turbulence must balance the tendency of the grains to settle". On this basis, the ratio of the transporting wind speeds for two different events will be equal to the ratio of the squares of the 'equilibrium' particle diameters.

The concept of a quasi-stationary size distribution related to wind speed is based on work by Gillette *et al.* (*J. geophys. Res.* **85**, 5621; 1980) who studied soil deflation as a function of soil properties and boundary layer micrometeorology. It is, however, debatable whether boundary layer turbulence processes can be extrapolated to the free troposphere where vertical transport and mixing is largely dependent on processes occurring in large-scale weather systems and during convection. Although Rea *et al.* cite some experimental evidence that they believe tends to support their assumption, there are no studies that directly address the relationship of particle size to the speed of the transporting winds.

Even the relationship between soil deflation and aridity is complex. Goudie (*Prog. phys. Geog.* **7**, 502; 1983) has shown that the correlation between dust storms and rainfall is very weak; indeed, the frequency of dust storms is at a maximum in regions with 100-200 mm annual rainfall. This is consistent with growing evidence that water is essential for the production of abundant quantities of fine sedimentary particles (Pye, K. and Sperling, C.H.B., *Sedimentology* **30**, 49; 1983) and for creating surficial environments where these weathering products can be deflated readily (Gillette *et al.*, *op. cit.*). In contrast, many hyperarid areas are relatively blown out; in such regions, the principal features of the surface are rocky plains and dune fields which are primarily comprised of coarse materials that are not readily deflated or transported great distances by winds. These factors suggest that the most abundant sources of soil dust are areas that are changing from moist to arid. This is supported by Prospero and Nees (*Science* **196**, 1196; 1977 and *EOS* **65**, 837; 1984) who demonstrated a threefold increase in the transport of dust out of North Africa and across the Atlantic during both the current drought and that of the early 1970s.

Another aspect that must be considered is the relationship between the meteorology of dust storms and weather. Studies of dust storms in Africa, North America and Asia suggest that if climate were to change, weather would also change and, with it, the sources of the dust, the mechanism by which it is generated and its transport paths. Sediments in the North Pacific would be particularly sensitive to changes in transport paths. Recent atmospheric chemistry studies in this region (Uematsu *et al. J. geophys. Res.* **88**, 5343; 1983) show that Asia is the primary source of the large quantities of dust found in North Pacific winds; it is carried out of Asia on westerly winds and, eventually, some fraction is transported via complex trajectories into the easterlies. As a consequence, dust concentrations decrease markedly in the latitudes south of about 30° N. Therefore, it is conceivable that dust deposition rates in some ocean regions could have changed substantially solely as a consequence of changes in circulation patterns.

Finally, the fact that large quantities of dust could have been produced by climatic factors not directly related to aridity must be considered. Most significant is the considerable evidence (Pye, K. *Prog. phys. Geog.* **8**, 176; 1984) that extensive areas of loessal soils found in North America, Europe and Asia have been formed through the combined action of winds and glaciation. The dearth of the fine particles in these deposits suggests that large quantities of fine soil dust were blown away, although the source region was not necessarily arid.

It is clear that deep-sea sediments contain a strong and varied aeolian signal that must be linked in some way with climatic processes on the continents. Rea *et al.* have taken the first step towards interpreting this signal. Whether their interpretation is correct will be established only by further studies of the areal and temporal variation of this signal in the sediments together with studies of the present-day relationship between weather and processes of dust mobilization and transport. □

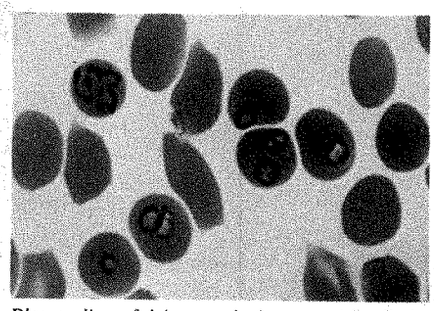
Parasitology



Chromosomes of malaria parasites and trypanosomes

from F.E.G. Cox

OUR understanding of the genetics of the protozoan parasites that cause major diseases in man has been hampered by the fact that we do not even know how many chromosomes they possess. On page 347 of this issue, Kemp and coworkers report the use of a new technique, pulsed-field gradient (PFG) gel electrophoresis, to separate and characterize seven chromosomes from the human malaria parasite *Plasmodium falciparum*[1] (see figure). This technique has enabled several groups not only to enumerate such elusive chromosomes but also to separate and identify them and to elucidate some of their functions. It has already been used to separate 11 of the 17 chromosomes of the yeast *Saccharomyces*[2].

PFG gel electrophoresis involves the separation of large molecules of DNA in an agarose gel[3], and the DNA obtained from the lysed organisms is subjected to alternate electrical pulses at right angles. Because these molecules are larger than the pore size of the gel, they have to orientate themselves end on to pass through the gel; their ability to reorientate at right angles and the time taken to do this provides a basis for separating the molecules. The DNA thus separated can be visualized by staining and blotting on nitrocellulose and the genes located by hybridization techniques. In this way, it is possible to locate and identify DNA molecules in the size range of 30-3,000 kilobases (kb), which happens to include most of the DNA constituting the chromosomes of malaria parasites and trypanosomes.

All that was previously known about the chromosomes of *P. falciparum* was that there are few of them and that they seem to be haploid in the blood stages[4]. Kemp *et al.*[1] studied three strains of *P. falciparum*, one from Papua New Guinea, which was used as a baseline, and others from Ghana and Thailand. Using lysed cultured blood-stage parasites, they found that their DNA separated out into seven discrete zones and, by using yeast chromosomes as markers and complementary hybridization data, they established that these represent complete chromosomes. The four smallest chromosomes were the easiest to identify and, in the Papua New Guinea strain, consist of 0.8, 1.2, 1.6 and 1.8 megabases (Mb). Chromosomes 5-6 were 2.2 and 2.6 Mb and chromosome 7, which overlapped with 6, was 3.0 Mb. The other strains of *P. falciparum* also had seven chromosomes but exhibited considerable polymorphism with respect to the Papua New Guinea strain. For example chromo-

Plasmodium falciparum in human red cells in culture. *P. falciparum* grows easily in culture, so is readily available for laboratory study. In this stained preparation, the nucleus appears as an amorphous dark mass with no detailed structure. Chromosomes can only be identified after separation by pulsed-field gradient gel electrophoresis. (Photograph A R Dluzewski.)

some 1, the smallest, varied between 0.8 and 1.0 Mb and others differed by as much as 20 per cent. There was also variation between the positions of the chromosomes in the agarose gel, but overall a common sequence of seven equivalent chromosomes of increasing size could be identified in each strain. There may also be other chromosomes, probably clustered towards the larger end of the size range where separation presents particular difficulties.

Having separated the chromosomes, hybridization techniques can be used to assign functions to them. The most striking gene products to be identified so far in malaria parasites are the short repeats of amino acids that constitute important antigens. Overall, it seems that the genes for these repetitive antigens are distributed between several chromosomes.

The antigen located on the surface of infected erythrocytes[5] is encoded by chromosome 1 and also, to a lesser extent, by chromosome 7; the secreted (S) antigen[6] is also associated with chromosome 7. It is of particular interest that five other repetitive antigens are associated with both chromosomes 5 and 6. Analysis of the results of hybridizations suggests that chromosome 5 is an exact but incomplete copy of chromosome 6 and that this chromosome, 5-6, is diploid, whereas chromosomes 1-4 are haploid.

The chromosomes of trypanosomes have not revealed their secrets so easily. The DNA of trypanosomes is divided between the nucleus and a unique organelle, the kinetoplast, which considerably complicates the study of the genetics of these organisms. Nevertheless, PFG gel electrophoresis is beginning to produce clues about the genes encoding the variant surface glycoproteins (VSG) that coat the trypanosome and are the basis of its ability to evade the immune response by antigenic variation.

Conventional agarose separation of the DNA of *Trypanosoma brucei* produces two fractions, a minichromosome band and the remainder of the DNA that stays at the starting position. PFG gel electrophoresis separates *T. brucei* DNA into four components, a minichromosomal fraction containing about 100 DNA molecules in the 50–150 kb range, about 6 chromosomes of 200–700 kb, 3 or more larger chromosomes of 2 Mb and a large heterogeneous fraction that hardly migrates at all from the starting point[7]. The genes encoding the VSG seem to be distributed among several chromosomes and are seen most readily in the minichromosomes. Recombination involves the transposition of large numbers of base pairs from one chromosome to another, resulting in major changes in the size distribution of the minichromosomes. It is possible to relate these size changes to changes in the expression of particular VSG genes, which cannot be done using more conventional techniques[8]. This leads to the question of whether minichromosomes are essential for antigenic variation. To answer this, van der Ploeg and colleagues have made a comparative study of several species of trypanosomatid flagellates[9]. PFG gel electrophoresis reveals tremendous differences between the chromosomes of different species. In contrast to *T. brucei*, *T. equiperdum* has few minichromosomes and *T. vivax* has no DNA smaller than 2,000 kb (ref. 9); as both can undergo antigenic variation it seems that minichromosomes are not essential for this process.

For a long time, parasitological problems have been emerging faster than the techniques available for their solution, which has resulted in frustrating gaps in our knowledge. PFG gel electrophoresis will quickly resolve some of these questions; the applicaton of this relatively simple technique represents a milestone in modern parasitology. It should soon possible to distinguish between genes encoding antigens important in protection and those used by parasites to evade the host immune response. It might also be possible to distinguish between virulent and avirulent strains of parasites and to pinpoint the basis of drug resistance. □

Geomagnetism

On the trail of Earth's tail

from Stanley W.H. Cowley

NEARLY all of the planetary bodies in our Solar System are believed to possess long magnetic tails extending for many tens to hundreds of planetary radii in the direction away from the Sun, but none has been so thoroughly investigated as that of the Earth. That has been particularly so since 1983 when the ISEE-3 spacecraft was sent on a series of passes extending about 230 Earth radii along the geomagnetic tail. Altogether, ISEE-3 spent around 8 months beyond the lunar distance, and provided unique and detailed data on the distant tail and its environs. Twenty papers arising from initial analyses of these data have recently been published in an issue of *Geophysical Research Letters*. These papers deal principally with the overall structure of the tail and the properties of plasmas and fields both in the magnetic tail lobes and in the central current sheet that separates the lobes.

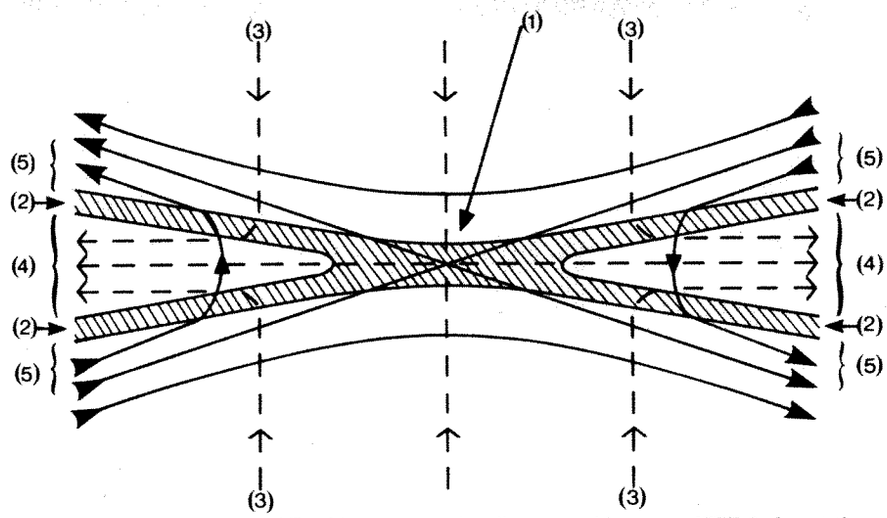
Magnetic tails are formed by an interaction with the solar wind, the tenuous hydrogen plasma which blows continuously outwards from the Sun at speeds of around 500 km s^{-1}. In the case of a magnetized planet, such as Mercury, Earth, Jupiter and Saturn, the tails are thought to result from magnetic reconnection on the dayside of the planet, a process which produces 'open' magnetic field lines mapping directly from the planet's polar regions into the solar wind. The flow of the wind then carries the field lines downstream from the planet and stretches them out into a nightside tail consisting of two bundles of oppositely directed magnetic flux (mapping to either pole) squashed together into a long cylinder. The field lines in the two tail lobes eventually reconnect across the internal interface between them, returning 'closed' field lines to the planet and 'disconnected' field lines to the solar wind.

Non-magnetized planets such as Venus and probably Mars also possess magnetic tails, but in their case the solar wind plasma becomes slowed on the dayside of the planet by its interaction with the planet's ionosphere. Field lines embedded in this slowed plasma become draped around the planet and stretched into an 'induced' tail as their distant 'ends' continue to move with the wind away from the Sun. A similar process is thought to be responsible for the formation of Type 1 comet tails. The phenomenon of magnetotail formation is therefore very common in our Solar System.

Although these basic notions have been commonly accepted for a number of years, detailed spacecraft observations of magnetotail plasmas and fields had been very limited before ISEE-3. Even in the case of the Earth's magnetotail, most observations had been confined to the region within the lunar orbit (60 Earth radii), a distance representing only about one-twentieth of the tail's theoretically estimated length. The papers in *Geophysical Research Letters* show how drastically the situation has been altered by the travels of ISEE-3.

Two of the papers demonstrate in very

different ways that the field lines in the tail lobes are indeed magnetically 'open', that is they eventually map across the outer surface of the tail into the surrounding solar wind. Changes in plasma bulk parameters, such as density, temperature and velocity, during ISEE-3 traversals of this boundary are reported by Gosling *et al.* [1], who find that well-defined transitions in the magnetic field (sharp changes in field magnitude and direction) are often accompanied by gradual variations in plasma parameters. These observations indicate the presence of direct magnetic flux linkage across the boundary, allowing solar wind plasma a relatively easy access. Abrupt plasma changes also occur, indicating a locally magnetically closed surface.



The second paper deals with the direction of the field in the tail and its dependence on the solar wind field direction, measured simultaneously upstream from the Earth by the IMP-8 spacecraft. Tsurutani *et al.* [2] find that the values of that cross-tail field component that lies approximately parallel to the central current sheet are positively correlated with the corresponding component in the solar wind. In effect, the lobe field (and that in the central current sheet) does not point directly along the tail axis towards or away from the Earth, but is somewhat skewed towards the direction of the solar wind field. This is precisely the result expected for an 'open' tail structure[3], arising from the effects of the magnetic stresses exerted on the plasma by the open field lines.

Equally interesting discoveries have been made about the hot plasma sheet particle population that carries the cross-tail current between the two magnetic lobes of the tail. A previous article in these columns[4] described the initial finding that beyond about 100 Earth radii, the flow of this plasma is directed almost exclusively away from the Earth, indicating that the tail reconnection region usually lies less far from Earth. The appearance of closed field loop 'plasmoids' in the distant tail about 30 min after the onset of magnetically disturbed periods has provided evidence of rapid tail reconnection near the Earth. Confirmation is provided by several papers describing energetic-particle, plasma and magnetic field observations and their relationship[5-7].

100 Years Ago

THE verdict of the jury who considered the case of the Usworth Colliery explosion is probably the first expression of opinion from a public body of this class that coal-dust and a small percentage of fire-damp can play the part that has hitherto been usually ascribed to fire-damp alone. They found that the explosion was caused by a shot, the fire of which acted upon "*the coal-dust and a small percentage of gas.*". The convenient and time-worn "outburst of gas" theory, which consigned the helpless miner to the vicissitudes of chance and exonerated colliery owners and their agents from all responsibility, seems on the point of giving way before the coal-dust theory.

From *Nature* **32** 61, 21 May 1885

The reconnection geometry of Earth's geomagnetic tail suggested by recent ISEE-3 observations. Broken lines are plasma streamlines, solid lines are magnetic field lines, and hatched areas represent regions of high electrical current density. A single current layer or diffusion region (1) at the site of reconnection bifurcates into slow mode shocks (2) in the downstream flow. Plasma flowing from the tail lobes (3) is accelerated across the shocks to form a hot plasma sheet (4) that flows away from the reconnection site on either side. Suprathermal particles, escaping upstream of the shocks, form boundary foreshock regions of streaming particles (5) located on reconnected tail-lobe field lines just outside the plasma sheet. (No attempt has been made to represent the asymmetries that would result from the observed flow of lobe plasma away from the Earth.)

An important subsequent discovery is that the interface between the tail lobe and the plasma sheet often has the character of a slow-mode shock wave[8]. The formation of such shocks resulting from magnetic reconnection was suggested by Petschek[9] over 20 years ago, but ISEE-3 has provided the first evidence for them. The field and plasma structure implied by the observations are shown in the figure. The single current layer separating the tail lobes at the site of reconnection (the 'diffusion region', where the field diffuses through the plasma) bifurcates on either side into two slow shocks standing in the plasma flow. Tail-lobe plasma flowing across the shocks is accelerated away from the reconnection region by the magnetic stresses to form a hot accelerated plasma (the plasma sheet) which is mainly confined beteween the shock waves[10]. However, high-speed ions and electrons are observed to escape upstream of the shocks to form 'boundary layer' or 'foreshock' regions of streaming supra-thermal particles, located on tail-lobe field lines between the surface of reconnected field lines mapping to the diffusion region and the shock waves (see figure)[11,12].

Scarf *et al.*[13] describe a well-defined plasma wave morphology associated with these structures. Electron plasma oscillations of a few kHz are observed in the foreshock region in association with a 'heat flux' formed by field-aligned streaming electrons that have energies above a few hundred eV. These waves therefore probably result form the Landau 'bump-on-tail' instability. A similar association seems to occur in this region between streaming energetic ions (of tens of keV) and the magnetosonic waves reported by Tsurutani and Smith[14]. Within the shock current sheet itself, a spectral peak in electric field noise at frequencies of a few hundred Hz, possibly identifiable as ion acoustic waves, is found[13]. An estimate of particle scattering by these waves suggests that they do not lead to appreciable resistivity; instead the lower hybrid drift instability (at too low a frequency to be measured by ISEE-3) may play an important role[13]. In my view, another important factor determining the structure of the current sheet is likely to be finite ion inertia.

An important question raised by these findings is whether the boundary of the plasma sheet on the earthward side of the tail reconnection region also has the nature of a slow shock. It would be surprising if this were not so in the more distant tail, but the near-Earth regime will be complicated by two factors. First, field line convergence at the Earth mirrors accelerated particles back in to the tail. Second, it is possible that the earthward-streaming plasma observed at the outer surface of the near-Earth plasma sheet predominantly results not so much from local acceleration as from the denser tail-lobe plasma found at somewhat larger distances. A deeper understanding of magnetotail physics will undoubtedly ensue from these and other considerations of the consequences of the ISEE-3 observations. □

The quest for pure electron lattices

SIR — The very interesting work on observing three-dimensional electron lattices, reported in News and Views[1], is even more widely relevant than discussed in the brief space available. We note here other laboratory experiments and also, perhaps surprisingly, some astrophysical theory. An essential point of departure stems from the (correct) observation in the article that it is "taken for granted that an electron lattice can form only if embedded in a neutralizing sea of positive electric charge". An electron lattice can be formed *without* such a neutralizing background.

It has been known for years that a magnetized Penning trap can stably store single charged particles for extremely long periods. Such a trap consists simply of an axially symmetric electric quadrupole (two negative electrodes with a positive ring electrode in between, preferably with hyperbolic cross-sections of the appropriate curvature) and a magnetic field along the symmetry axis. The magnetic field prevents a charged particle from escaping across the magnetic field and the quadrupole electric field confines the particle (if negatively charged for the above charging of the electrodes) along the axis. Until fairly recently, it was not understood what happens if one fills such a trap with a large number of particles. Older literature vaguely discussed 'clouds' of trapped particles. It is now known that the charged particles condense effectively to form what appears very much to be a liquid. That is to say that the particles are confined to a spheroidal volume of constant density with a sharp interface to the surrounding vacuum. These sharp discontinuous surfaces were predicted theroretically for both the laboratory and astrophysical cases[2,3]. The surface thickness separating the plasma from the vacuum is shown to be only of the order of the Debye length, which is small compared with the system scale in the neutron star case even for million-degree plasmas, and in the laboratory case for the relatively cool plasmas that can be produced there (room temperature or less). Moreover, such systems ('non-neutral plasma' is the usual term in laboratory circles) have been created in the laboratory with both electrons[4] and ions[5]. Indeed, in the case of the ions, the particles have been cooled to a temperature (0.1 degrees kelvin) where the system should not only appear liquid-like (confinement to a variable shape volume of constant density) but actually be a liquid in the sense of large particle–particle correlations. Future experiments aspire to produce a trapped solid of ions (D.J. Wineland, personal communication). The workers at the University of California at San Diego have trapped the electrons in a similar configuration, using ring electrodes at the ends of a long solenoid that parallels the magnetic field axis. It may be feasible to cool such trapped electrons to temperatures where they are liquidized or solidify[6]. In either case, the formation of an ideal 'theoretician's' lattice of totally non-neutral plasma free of interfering background neutralizing charges seems within reach.

In the case of astrophysics, solidified states of matter have been expected for neutron star interiors (for example, refs 7,8). However, it now seems increasingly possible that the exteriors of magnetized neutron stars may, in many cases, be surrounded by such quasi-liquid non-neutral plasmas pulled from their surfaces. The essential ideas were forwarded by a number of people such as Holloway[9] who pointed out the likelihood of vacuum–plasma interfaces, Rylov[10] who first speculated on how such plasmas might be distributed about pulsars, and Jackson[11] who also argued for condensation of such plasmas about neutron stars. The laboratory effort itself goes back at least to Trivelpiece[12], and an entire book has been written on the properties of nonneutral plasmas[13].

Not only do these remarkable plasma experiments open up the possibility of creating pure liquid and solid plasmas, but they also underscore an interesting convergence in research on solid-state physics[14], with laboratory experiments on non-neutral plasmas and, surprisingly, some astrophysical theory as well.

Selfish DNA and the origin of introns

SIR — The selfish DNA or transposon theory of the origin of introns[1-9] is dismissed far too readily by Cornish-Bowden[10]. As introns are very often not at domain boundaries[11,12], the hypothesis of evolutionary exon shuffling to recombine protein domains is hardly the "most plausible suggestion" for their "function". It does not adequately explain either the origin or the evolutionary maintenance of RNA splicing. Although fusion of two genes by recombination between existing introns probably has been evolutionarily important, it does not explain the origin of the introns "in the first place". *De novo* intron formation by fusing two genes lacking introns is far more complex than fusion to produce an unsplit gene; it could hardly have occurred in a single step in an organism previously lacking RNA splicing[7]. Split genes and RNA splicing could not have evolved merely because they might millions of years later help a new protein evolve: evolution lacks such foresight[2].

The transposon hypothesis can explain the origin of introns and also of RNA splicing itself[3-7]. The presence of introns in mitochondria and chloroplasts, in particular, is best explained by transposition from the nucleus[5-7]. The different positions of the introns of the chloroplast *psbA* genes of *Chlamydomonas*[13] and *Euglena*[14], coupled with their absence from the ancestral cyanobacteria[13], supports insertional origin for chloroplast introns, rather than one from primordial gene fusions that created the *psbA* gene. The coding of proteins involved in splicing by certain introns in fungal mitochondria[4], and in a chloroplast gene[15], supports the thesis that such introns originated as defective transposons in which the RNA-splicing enzymes evolved from pre-existing DNA splicing enzymes specific for their termini[3-5].

This also can explain the origin of introns in general [3,4,7]. Suppose a transposon capable of precise excision inserted into a cellular gene, thus inactivating its transcript[4]. This first 'intron' would be exactly pliced out of the RNA if the DNA excisionase of the transposon mutated so as to be able to cut RNA instead of DNA, but retained its specificity for the sequence at either end of the transposon; this would simultaneously prevent its self-transposition and rescue the cell from its harmful insertion mutation.

This mutation would protect the cell from insertion mutations by any transposons generating similar terminal sequences upon insertion, and therefore have allowed the rapid intragenomic spread of kindred non-defective transposons; moreover these would have provided DNA excisionase activity allowing the rapid intragenomic spread of the defective RNA-splicing transposon itself[7]. So many genes would quickly acquire introns that RNA splicing could never be lost[1,2]. All descendants of this cell would be permanently infected with useless introns. RNA splicing could later acquire real functions for at least some genes, such as differential splicing to make different proteins from the same transcriptional unit[16]. This rescue hypothesis[4] provides an immediate and powerful mode of spreading for introns and RNA splicing. At one and the same time it involves intragenomic kin selection favouring the spread of selfish DNA, and conventional selection at the cellular level for protection from the harmful effects of certain selfish transposons. Alternatively, RNA splicing might have originated in a virus[7] before being taken over by the cell.

The transposon theory of intron origins best fits the nuclear mRNA and rRNA splicing mechanisms, both of which depend on specific sequences within, as well as at the end of, introns[17]. I suggest that they originated in an early eukaryote and were never present in prokaryotes. The small nuclear RNAs involved in nuclear pre-mRNA splicing might initially have been synthesized from transposon promoters lying on the DNA strand opposite the transcribed strand of the cellular gene into which it had inserted. But nuclear tRNA splicing does depend on specific intron sequences and may have originated independently; the presence of similar tRNA introns in the archaebacterium *Sulpholobus*[18] suggests that it originated before archaebacteria and eukaryotes separated. Chloroplast tRNA introns seem unrelated to nuclear and archaebacterial tRNA introns; they resemble mitochondrial and nuclear rRNA introns and have features suggestive of defective transposons[6,15,19].

The improbability of losing every single intron by accidental deletion[2,4], and the extra complexity that splicing poses for the origin of protein coding[4], make it improbable that RNA splicing was the general rule in the primordial cell, and favour the view that archaebacteria and eukaryotes both evolved from a eubacterium lacking split genes[4]. Once introns evolved, their number and total length per genome would increase or decrease in response to generalized selection for larger or smaller total genome size[1] and transcript size, as well as to selection for specific functions[16] for at least some introns.

The relative uniformity of exon length in protein-coding genes is not, as claimed by Lonberg and Gilbert[12], good evidence against an insertional origin. The periodic structure of chromatin may prevent totally random insertions. The correspondence between the three major peaks in exon size distribution and the DNA lengths in nucleosome core particles, linkers and whole nucleosome[20], suggests that the junctions between linkers and core particles have been 'hotspots' for intron insertion and therefore that introns in protein genes originated after the origin of eukaryotic chromatin. By contrast, exon length in mitochondria [20] and chloroplasts[13,14,21,22], which lack histones, is much less uniform and more random than in nuclei.

Chemical warfare evidence unconvincing

SIR — Rosen *et al.*[1] fail to substantiate their contention that environmental samples from south-east Asia provide evidence of chemical warfare. They base their argument on reports of trichothecene mycotoxins in six samples from alleged chemical attack sites[2,3]. In arguing that the toxins they reported were not of natural origin, they astonishingly say that the US Army Chemical Systems Laboratory found no trichothecenes in samples from south-east Asia.

This incorrectly implies that the Army's samples were controls. In fact, at least 60 of the Army's samples, like those of Mirocha and Rosen, were from alleged chemical attack sites. As far as we know, the Army laboratory has not found trichothecenes in any sample from such sites. Mirocha and Rosen have known of this since at least October 1983, when one of us (M.M.) wrote to them asking "Why does the Army find no positives out of 60 samples while Mirocha plus Rosen find six out of six positive?" The evidence for trichothecenes at sites of alleged chemical warfare is inconclusive at best: 6 positives out of 6 samples compared with 60 negatives out of 60 samples.

Rosen *et al.* ignore the fact that it is pollen, and not trichothecenes, which is the consistent and confirmed finding in samples of yellow rain, the alleged chemical warfare agent. Since 1979, many samples have been turned in by Hmong refugees from Laos, and then examined by US and other investigators. In November 1982, the head of the US Army laboratory referred to above stated "most of the samples that are of yellow rain are fairly dry and they have a high level of pollen grains in them"[4].

To our knowledge, *all* samples of yellow spots and powders from sites of alleged chemical attack that have been examined under the microscope, including those analysed by Mirocha and Rosen, consist largely of pollen. This is also true of honeybee faeces. Moreover, our analysis of the pollen types in samples of the alleged agent collected by Hmong in April 1981 and in March 1982, and comparison with pollens gathered by local honeybees, strongly supports the identification of yellow rain as the faeces of south-east Asian honeybees[5].

Rosen *et al.* also ignore descriptions of the alleged agent by Hmong refugees. Summarizing interviews with Hmong for the period 1978-82, the official reports of Secretaries of State Alexander Haig and George Shultz state that the alleged agent is yellow and falls like rain[6,7]. This resembles mass defaecation flights of the giant Asian honeybee, *Apis dorsata*, which two of us (M.M. and T.D.S.) observed in Thailand in March 1984[8]. Although now realized to be common, such flights were previously unknown, perhaps because they occur at so great a height, even though hundreds of thousands of bees may be involved. Further, nearly all the Hmong to whom we showed bee faeces on leaves failed to identify them. Some said they were *kemi*, a Hmong term for the alleged chemical warfare agent.

Our conclusion that yellow rain is probably the faeces of honeybees and not a chemical warfare agent is thus supported by Hmong accounts of its appearance by pollen analysis, and by observations of the behaviour of honeybees in south-east Asia.

Studies of the yellow rain phenomenon in several countries, particularly in government laboratories, have still to be made public. It is to be hoped that the responsible officials will make every reasonable effort to move further investigation of this problem into the normal channels of scientific communication.

Somatotopic map of the flying fox

SIR — In the interesting article by Calford *et al.* on the unusual somatotopic cortical map in the grey-headed flying fox, *Pteropus poliocephalus*, and also in the comment by Jones[2] on the article, one point escaped emphasis: the caudal shift of the somatotopic representation of the distal forelimb has taken place by reflection from rostral to caudal (that is the first digit or thumb remains lateral and adjacent to the face), instead of by rotation from rostral to caudal (in which event the thumb would lie medial and the fifth digit would be located adjacent to the face). In contrast to the reflection of the representation of the forelimb, the representation of the hindlimb appears to have rotated through about 90 degrees, so that it points medially (instead of rostrally as in most mammals). Whether this difference in the shift of the fore- and hindlimbs is related to their different functions (flying and feeding in the case of the forelimb, landing from flight in the case of the hindlimb) remains an open question.

Jones[2] has addressed a related issue: what is the advantage of representing the body surface on flat cortical maps instead of as a bolus of cells? Rostral/caudal and medial/lateral appear to be the spatial relationships in the periphery that need to be maintained in the cerebral cortex; dorsal/ventral seems a less important direction, being coded sometimes as caudal/rostral (for example in the axial/distal parts of a limb in quadrupes) and sometimes as lateral/medial (for example in the position of the head relative to the limbs and trunk). If, then, one direction in the periphery does not have to be maintained in the cortex, a flat map can achieve all that a bolus would achieve, with the advantage of much less complex connections between thalamus and cortical surface.

Spatial relationship and extrafoveal vision

SIR — A recent letter by Rentschler and Treutwein[1] describes a qualitative difference in human visual acuity between central foveal vision and a region 2° from the fovea when the task is to discriminate between stripe patterns that differ in appearance but are mathematically similar in everything but phase relationship between first and third spatial harmonics. For the pairs that are easily discriminated both foveally and at 2°, the appearance of the stripes differs in the contrast of a narrow dark band on a lighter grey stripe. In the patterns that can be discriminated foveally and at 2°, the darker bands in each discrimination task are identical in quality and differ only in that their position with respect to the lighter bands is mirror-image reversed in the two images.

Rentschler and Treutwein conclude that (1) there is a qualitative difference between foveal and nonfoveal vision for spatial localization tasks but not for contrast detection tasks, and that (2) because of this difference between foveal and nonfoveal vision for one type of task but not the other, there must be two types of visual processing involved. We suggest that there might not be a qualitative difference between foveal and nonfoveal vision, but rather a quantitative difference — spatial localization might simply decline faster than contrast detection as a function of eccentricity — and that this difference can be explained at least partly in terms of receptive field size and stimulus resolution in complex cells at various levels in the visual pathway, as a function of eccentricity.

Both the letter itself and the accompanying News and Views article by Watt[2] are couched in terms of the Fourier-analysis theory of cortical function; curiously no mention is made of known receptive field properties of cortical cells. As an alternative to their interpretation, which assumes that the early stages of vision can be regarded as a number of parallel spatial filters (a view that our receptive field studies do not seem to support), we would propose an interpretation (or perhaps a more physiological translation of their interpretation) in terms of the known properties of *complex* cortical cells. At a given eccentricity, the territory of visual field over which a complex cell can be activated is usually much larger than that of a simple cell, but the optimum stimulus size is approximately the same. A complex cell responds optimally to lines or slits in a specific orientation, but for an optimal response the line width is also critical. The optimal line evokes a response wherever it is shone over a wide area, even though a line thick enough to cover this entire area evokes no response at all. The optimal line width is roughly the same as the width of the region from which a simple cell can be activated, or the diameter of a retinal ganglion cell receptive field centre (for the same eccentricity), implying a preservation of acuity but loss of the spatial localization conveyed by simple cells.

This relative loss of what may correspond to spatial localization without loss of acuity is seen not only in complex cells in area 17, but even more strikingly in prestriate visual areas. Rovamo and Virsu[3] have shown that human visual acuity at different eccentricities varies as a linear function of cortical magnification in area 17, and Rentschler and Treutwein therefore use magnification to scale the size of their two test patterns for eccentricity: they compare foveal and nonfoveal discrimination using only this one stimulus size ratio. This may be justified if one assumes that resolution (that is, acuity) as a function of eccentricity does not change as one goes further along in the visual pathway; physiological comparisons of areas 17 and 18 (see our paper, this issue[4]) support this assumption. But we think that magnification in area 17 might not be an appropriate scaling factor for tasks involving spatial localization. Spatial localization could well depend on the size of complex receptive fields, and that clearly does increase beyond 17, for example, in 18, V4 and MT, and also increases more rapidly for nonfoveal than for foveal vision.

The difficulty in discriminating mirror-image patterns is more likely to be related to spatial localization, and consequently tailoring stimulus size to cortical magnification in area 17 may be inappropriate. The mirror-image (spatial localization) discrimination is already poorer than the contrast discrimination in the fovea (Fig. 2 of ref. 1) and falls off more rapidly with eccentricity. This parallels the behaviour of complex cells at more central levels of the visual system than area 17. Thus the finding would seem to suggest not a qualitative difference in handling of form foveally and peripherally, but a difference in rates of deterioration with eccentricity between acuity as commonly defined, and something else, possibly spatial localization.

We further suggest that these results do not necessarily implicate two separate visual processes for contrast discrimination and spatial localization. The fact that the relative loss of spatial information seen physiologically in single cells is paralleled in these psychophysical observations suggests to us that spatial localization and contrast information are probably encoded in the same cells and not by separate processes. Only if psychophysical spatial localization were better than predicted by the physiology of complex cells would one need to invoke a separate process for it.

Lysosomes and prohormone activation — correction

IN the letter from C. N. Hales under this title in *Nature* of 7 March (Vol. 314, 20) an editorial change altered the sense of the final paragraph which should read:

> The sequence information which has emerged to date is consistent with the lysosomal hypothesis, suggesting that it may provide a useful framework for making and interpreting structural comparisons in this area.

The hypothesis referred to is outlined in the second paragraph of the letter and in more detail in the ref 3 and 4 in the list cited.

How many orbiting lasers for boost-phase intercept?

from Richard L. Garwin

A constellation of laser battle stations in low Earth orbit could intercept intercontinental ballistic missiles (ICBMs) in their boost phase. If such lasers are available decades hence, they will face fast-burn ICBMs and find their task more difficult. How difficult is shown by an elementary analysis taking into account laser retarget time.

PRESIDENT Reagan's Strategic Defense Initiative (SDI) for countering Soviet nuclear-armed intercontinental-range ballistic missiles (ICBMs) and submarine-launched ballistic missiles (SLBMs) puts great stress on interception of the missiles in boost phase. Although the feasibility of a star wars defence will stand or fall by the ease of countering the system, it is of some interest to know how many satellites of given characteristics would be required to destroy boosters in the numbers and with the characteristics that may be available by the time such a defence could be mounted. (See ref. 1 for a technical introduction to boost-phase intercept.)

The emphasis given in this discussion to the need to destroy most ICBMs while the rocket booster is still burning is consistent with the general supposition by SDI supporters that this would be essential even to partial defence, because the missile is then more visible and more vulnerable than later, when the reentry vehicles and any decoys may have been deployed; moreover, in the boost phase there are fewer targets to be destroyed.

The Soviet silos lie deep within the Soviet Union, and two basing modes have been suggested for boost-phase interception. The first entails large numbers of low-orbit satellites carrying powerful lasers or homing rockets, so that there will always be enough within range of any silo to destroy the ICBM launched therefrom. The second involves pop-up interceptors based on submarines near the Soviet Union, that would be launched on information that a massive ICBM launch had taken place and which would destroy missiles in boost phase with X-ray lasers powered by nuclear explosions. If the X-ray laser is assumed feasible and effective, the need to bring it above the curve of the Earth during the duration of boost of the ICBM requires an interceptor mass far larger than the payload mass itself. Thus[2] an interceptor based 7,400 km from the silo, required to climb in 120 seconds to an altitude giving a line of sight with 185-km Earth-limb clearance to a booster which has climbed to 370 km altitude, would have an initial mass of 660 tons to lift an X-ray laser payload of 1 ton. This assumes no structural mass needed for the rocket, a specific impulse of 300 seconds (exhaust velocity of 3 km s^{-1}) and instantaneous burn of the interceptor rocket propellant. To reach the same altitude in 60 seconds would require twice the speed and an initial mass of 430,000 tons. These are some of the reasons why what follows concentrates on the characteristics of the first basing mode for SDI, a satellite constellation.

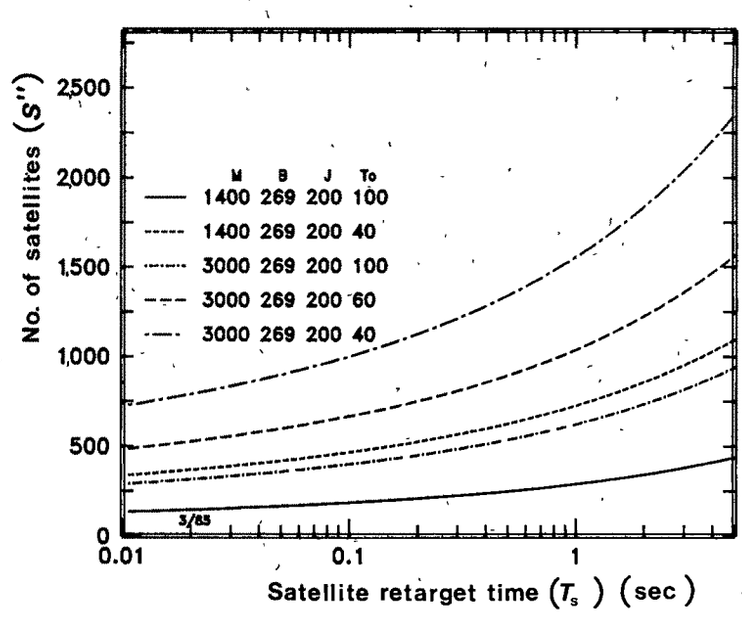

Fig. 1 The number S'' of our standard laser satellites is plotted against assumed laser retarget time for two assumed booster numbers and 3 assumed engagement times during boost phase. Against the clustered launch of 3,000 boosters of 40-s engagement time, 1,344 satellites of 0.5-s retarget time in optimum orbit are required, working perfectly reliably, to dispatch the boosters.

Counter measures

In what follows, I consider the likelihood that there will emerge counters to the assumed defences, for example, by the evolution of the Soviet ICBM force to small single-warhead missiles equipped with fast-burn boosters. Such missiles, perhaps burning out in 50 seconds at an altitude of 80 km, would negate the pop-up interceptor in two ways: first, it could not climb to line-of-sight within 50 seconds, while the soft X-rays could not penetrate to 80-km altitude within the atmosphere. Studies made for the US government in July 1983, by McDonnell-Douglas and Martin-Marietta, indicate that such fast-burn boosters with MIRVs and penetration aids could be built at a cost of only some 10–15 per cent more than optimized (normal-burn) boosters. Indeed, given that the cost of the missile guidance systems may be much reduced, a silo-based single-warhead ICBM could even be cheaper per warhead than a new MIRVed large missile because of economies of scale in production, and the much cheaper development and test programme.

Missile defence based on satellites in low Earth orbit would provide continuous visibility from some satellite to each booster, but fast-burn missiles would again negate the capability of both X-ray lasers and neutral particle beams (hydrogen-atom beams of 100-MeV energy) because of the screening of the atmosphere. Homing interceptors would have little time to reach the boosters and the atmosphere at 80-km altitude would

interfere with their infrared homing. Satellites carrying powerful continuous-wave or repetitively pulsed infrared lasers can, at some wavelengths, see down to the clouds and might have significant capability against individual missiles, even fast-burn boosters. We assume that a 50-second-burn booster could be engaged for 40 seconds by such a satellite fleet, but note that such large satellites would need to be protected against Soviet antisatellite weapons.

There are few published analyses of required numbers of laser battle stations, and these are examples of methodology rather than conclusions, since they neglect the relationship between a satellite's vulnerability and its altitude, assume zero retarget time, and make other simplifying assumptions. Carter[3] chooses to deploy his satellites on 1,000-km altitude orbits and, for booster hardness half that assumed here, estimates 160 satellites required to handle the present 1,400 Soviet boosters as they are now distributed. For the same boosters deployed "in one region", Carter estimates that 500 satellites are required.

Other estimates[4] point to a requirement of 300 lasers, or 800 lasers (the latter estimate involving satellites at 1,000-km altitude deployed in orbits of optimum inclination and assumed to destroy a booster out to 3,000-km range in the 7 seconds required at 3,000 km). The assumption that satellites are deployed for uniform coverage of the entire globe[5] leads to a requirement for some 2,400 satellites[6].

In unpublished Los Alamos documents of 4 May and 6 August 1984, G. H. Canavan[7] assumes satellites distributed uniformly over the entire globe and asserts that for boosters uniformly distributed over a very large region, satellite numbers required grow only as the square root of booster numbers (or hardness) because satellites uniformly deployed will be closer together and will destroy boosters at shorter average range. These results are cited in ref. 8. For deployment in a small region, Canavan also obtains satellite numbers proportional to the number of boosters.

C. T. Cunningham[9] assumes 300-km orbit altitude, with 60-deg. orbits; using a dynamic simulation, he finds that only 60 satellites are required—noting however that his simulation requires "that the switching time be much less than the dwell time of 42 milliseconds at the minimum target distance of 100 km."

The present analysis explicitly considers retarget time for both distributed and regional basing of ICBMs. We consider a constellation of satellites assumed to provide, over the region of ICBM silos, an areal density s (number of satellites per unit area) adequate to destroy all ICBMs, assumed launched simultaneously and burning out in time T_0.

The derivation of the overall number of satellites S from the required local areal density s entails the calculation of s as a function of orbit parameters. Satellites in a mixture of orbits giving uniform density everywhere will occupy $4\pi E^2 = 509(\mathrm{Mm})^2$ of area, so that $S = 509s$. Launch sites clustered at the North Pole could be attacked most effectively with polar-orbit satellites, which have a much larger latitude-band-averaged density at $\lambda = \pm 90°$ than elsewhere. Silos limited to the Equator could be efficiently addressed by equatorial low-Earth-orbiting satellites. In general, there will be an optimum orbit to attack boosters launched from silos spread uniformly from latitudes λ_1 to λ_2. If we assume satellites uniformly phased in orbits of optimum inclination i, the band-averaged satellite density

$$\langle n \rangle_{\lambda_1,\lambda_2} \equiv \frac{\int_{\lambda_1}^{\lambda_2} n(\lambda) \cos\lambda \, d\lambda}{\int_{\lambda_1}^{\lambda_2} \cos\lambda \, d\lambda} \qquad (1)$$

where $n(\lambda)$ is the satellite density averaged by Earth rotation for latitude λ. This is an optimistic measure. For satellites of very short range, the constellation capability is limited by $\min(n(\lambda))$ over $\lambda_1 < \lambda < \lambda_2$. For long-range satellites, those outside the latitude range will have to be considered, which will reduce the average density below that calculated here, so that the concentration factor y derived here is an over-estimate, especially because the granular satellite density is assumed uniform.

For N satellites on any orbits of inclination i, the longitude-averaged

$$n(\lambda) = (N/2\pi^2)/(\sin^2 i - \sin^2\lambda)^{1/2} \qquad (2)$$

for $\lambda < i$, and $n(\lambda) = 0$ for $\lambda > i$. Averaging over a band from λ_1 to λ_2, we have for such orbits

$$\langle n \rangle(\lambda_1, \lambda_2) = (N/2\pi^2) \times \frac{[\sin^{-1}(\sin\lambda_2/\sin i) - \sin^{-1}(\sin\lambda_1/\sin i)]}{(\sin\lambda_2 - \sin\lambda_1)^{-1}} \qquad (3)$$

(for $\lambda_1 < \lambda_2 < i$, and with obvious modifications for $\lambda_2 > i$). For silos spread uniformly between 50° and 60°, the maximum concentration factor y is reached with orbital inclination $i = 60°$, and is $y = 3.1$, which we have used in constructing Table 1 and Fig. 1. Thus we multiply required satellite densities by 164 $(\mathrm{Mm})^2$, confident that the resulting number of satellites will always be an underestimate.

We assume a steady or rapidly pulsed laser on each satellite, provided with an optically perfect diffraction-limited mirror of diameter D which is refocused at the range of that booster which is the target of the moment. (The Hubble space telescope will have $D = 2.4$ m; demonstration of even megawatt diffraction-limited chemical lasers is several years away in the SDI programme.) The laser is assumed to have a steady output power P and wavelength λ. For a uniformly illuminated output aperture of area $A = \pi D^2/4$, the maximum possible power density at any point in the focal spot at range r is obtained from the brightness B of the laser (power per steradian of solid angle) as $p \equiv B/r^2$. In turn, B is given precisely by $B = PA/\lambda^2$, which can be shown by integrating over the radiating aperture to obtain the electric field a short distance away, and comparing with the electric field when the entire aperture is phased to provide a focus at distance r.

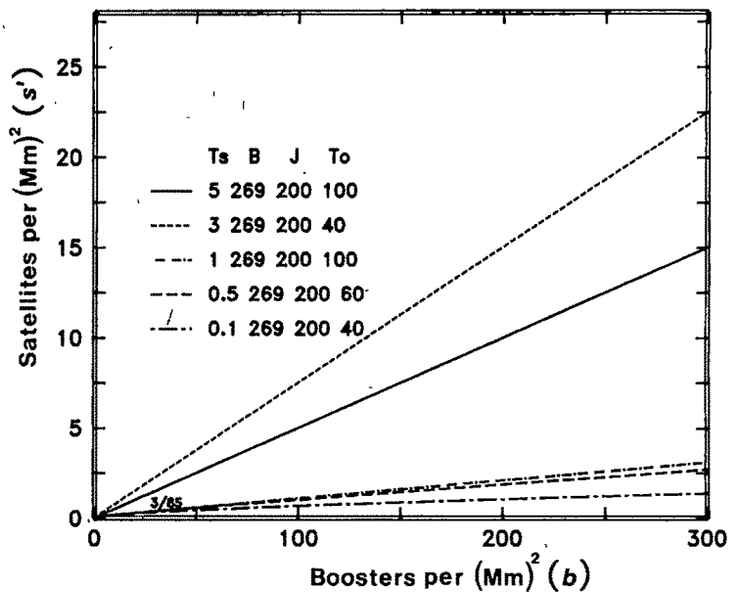

Fig. 2 Perfect satellites as in Fig. 1 are uniformly distributed at optimum (near-zero) altitude above a distributed booster density of b and are constrained to shoot within their tiling hexagons. Soviet missiles are said[3,4] to number 1,400 and be distributed over an area of 10 $(\mathrm{Mm})^2$; thus $b = 140$. With a 5-sec laser retarget time and 100-sec engagement time, some 5.8 satellites per $(\mathrm{Mm})^2$ are needed—or 950 in optimum orbit world-wide.

In the numerical examples we consider $P = 25$ MW, $D = 10$ m, $\lambda = 2.7$ micrometre (hydrogen fluoride). We thus take $B = 2.69 \times 10^{20}$ watts per steradian. At $r =$ 3,000 km or 3 Mm, the power density is thus 30 MW m^{-2}. We assume a booster hardness $J = 200$ MJ m^{-2}, which is sufficient to evaporate a layer of carbon 2 mm thick. Then the time $t(r) = Jr^2/B$ required to deliver the assumed lethal heat is 6.7 seconds. Such calculations assume that the satellites can see the boosters sufficiently clearly and can point sufficiently accurately and stably that the power density at the peak within the 1-m diameter spot (at 3-Mm range) is not diminished by spot wander exceeding a few tens of cm during the 40 km or so travel of the booster during the 7-second engagement.

As one considers countering missiles with boost times ranging from the 300 seconds or so of the Soviet SS-18 to the 180 seconds of the US MX missile and to the 40 seconds of a fast-burn ICBM, the need arises either for more satellites or for satellites at closer range. Furthermore, particularly for powerful satellites or for close-range engagements, the time T_s required for the laser satellite to retarget, to slew and settle the beam to the necessary accuracy of 0.1 microradian or better, plays an important role in determining the size of the constellation.

Our programme is first to calculate, for a flat Earth and a planar satellite constellation at altitude h, the number of missiles launched from a region that could be killed by a constellation of satellites with particular density and laser characteristics. We then extend that calculation to the more realistic case of a spherical Earth, obtaining a reasonably accurate closed-form expression (Fig. 1). Next we calculate the missile-killing potential of an assumed satellite constellation density above a uniform areal distribution of boosters, for which each satellite is assigned the boosters within its circle of responsibility (Fig. 2). This would be a reasonable assignment strategy for boosters covering the entire Earth at uniform density, but it has also been used to justify "square-root scaling" of satellite numbers against booster numbers for boosters deployed over 10 (Mm)^2, taken to be the deployment area of the 1,400 current Soviet ICBMs[7,8]. The results are tabulated in Table 1 and discussed for some cases of interest.

Although there seem to be no published results on laser constellation size for finite retarget time, our calculations show the great importance of the time required to move the beam from one booster to the next.

Clustered launch

We now turn to the problem of relating local satellite density to the number of boosters to be destroyed. For M_0 boosters all launched simultaneously from a point, and if a satellite constellation of local density s and brightness B, deployed at altitude h, is assigned to kill them, we assume a continuous distribution of satellites and that the beam is always normal to the booster surface. Since the time to kill a booster at distance r is Jr^2/B, a satellite at distance r can kill $m(r) = (BT_0/Jr^2)$ boosters in the available boost time T_0.

The missile-killing potential of the constellation against clustered launch is then obtained by integrating $m(r)$ over all satellites from those directly above the launch site ($r = h$) to some maximum r. We cut off the integral at $r = U$, defined as the distance beyond which a satellite can no longer kill even one booster. Then U is given by $m(U) = 1$, or $U^2 = BT_0/J$. This calculation optimistically takes credit for fractional kills above unity. Each satellite closer than U is assigned a different booster and heats it for the required time before being assigned and moving instantly to heat another. The number of boosters that can be killed, M, is then

$$M = \int sm(r)2\pi\rho \, d\rho = (BT_0/J) \int_{\rho=0}^{\rho=\max} \frac{2\pi s\rho \, d\rho}{(h^2+\rho^2)} \quad (4)$$

where the coordinate system is fixed at the booster launch point, the integration runs over the various satellites and ρ is the radius from the origin to a sub-satellite point. With $a \equiv r^2 = h^2 + \rho^2$,

$$M = \pi s(BT_0/J) \int_{a=h^2}^{a=U^2} da/a = \pi s(BT_0/J) \ln(U^2/h^2) \quad (5)$$

$$= \pi s(BT_0/J) \ln(BT_0/Jh^2) \quad (6)$$

For the 25-Mw 10-m diameter HF laser described earlier, we have $B =$ 269 Mw(Mm)^2 m^{-2}, $J = 200$ MJ m^{-2} and, for $T_0 = 100$ s, $U = 11.6$ Mm. For $h =$ 500 km (0.5 Mm), the logarithm is about 6 and varies only slowly with h.

A planar constellation of one satellite per square megametre and zero retarget time, consisting of some 164 satellites in optimum orbit covering only Soviet ICBM sites, could thus destroy 2,657 missiles of the assumed characteristics. But, as will be seen, the recognition of satellite retarget time of 0.1, 0.5, or 3.0 seconds reduces this capability to 2,475 2,107 and 1,468 boosters respectively. The imposition of horizon limitations for the case of a curved Earth will then further reduce the capability of the constellation.

Table 1 Required satellite densities s, and numbers S.

M boosters	J (MJ m^{-2})	T_0 (s)	T_s (s)	s' (per (Mm)^2)	S'	s'' (per (Mm)^2)	S''
1,400	200	100	3	4.24	697	2.32	381
1,400	200	40	3	10.54	1,732	5.80	953
3,000	200	40	3	22.5	3,699	12.43	2,044
1,400	200	100	0.5	0.89	146	1.53	251
1,400	200	40	0.5	1.96	322	3.82	628
3,000	200	40	0.5	3.97	653	8.18	1,344
3,000	200	100	0.5	1.71	281	3 27	537
1,400	200	100	0.1	0 48	79	1.14	187
1,400	200	40	0.1	0.84	138	2.85	468
3,000	200	100	0.1	0.76	126	2.44	401
3,000	200	40	0.1	1.39	228	6.10	1,003
Boosters distributed over 10 (Mm)^2 (solution of Eqn. 18): (Lasers assigned local areas of responsibility) (Flat Earth, satellite numbers will be greater than shown)							
Concentrated boosters with horizon cutoff of satellite effectiveness: (Round Earth, solution of Eqn. 13, optimum altitude $h^2 = (BT_s/J)$) For $T_s = 3$, 0.5, 0.1 seconds, h is 2,010, 820, or 370 km, respectively. The point-launch approximation holds for $G \leq h$, where G is the diameter of the launch field							

Orbiting satellites carrying 25-MW lasers of 2.7 μm wavelength and with 10-m diameter perfect mirrors (brightness $B = 2.69 \times 10^{20}$ W per steradian) are placed in near-optimum 60° inclination orbits for boost-phase intercept of ICBMs near 55° latitude. The last two columns present the local satellite density s'' to destroy the indicated number of missiles of boost time (engagement time) T_0, with satellites of retarget time T_s, assuming the missiles concentrated in a region not much bigger than the altitude of the satellites. Total number S'' of satellites needed is obtained by multiplying s'' by the surface area of the Earth—509 (Mm)^2—divided by a concentration factor of 3.1. For this concentrated launch, optimum orbit altitude (Eq. 12) is 2,010, 820, or 370 km respectively for retarget times of 3, 0.5, or 0.1 s. Columns s' and S' are an improved analysis of an assumed distribution of boosters clearly inapplicable to the parameters discussed here—as if boosters were deployed at constant density everywhere, with satellites constrained not to shoot at a booster if there is a satellite closer to that booster. This model would clearly require more satellites than if an optimum assignment were used, as in calculating the density s'' against clustered launch. Equally clearly and primitively, distributed boosters should be an easier task for the defence—a correct intuition contradicted by the comparison of 697 satellites and 381 satellites in the first row of the table. The discrepancy arises because the assumed model[7,8] is inappropriate.

Flat Earth and non-zero retarget time. A 10-m diameter mirror cannot move instantly from one target to another. The Hubble space telescope has a settling time of 3 seconds for the smallest motion within a beam-width (about 0.2 μradian), and will take several minutes to move to a new target. Because of the large laser power at the mirrors, it is not possible to make use of tricks often used in optical systems for compensating imperfect figure or orientation of large elements by the deformation or motion of smaller elements. For the same reason, and because the beam must be moved typically 6° or so between targets (some 4×10^5 beamwidths) electro-optical phase-shifting coatings cannot do the job. It might be possible to retarget a 10-m mirror to within 0.1 microradian or less in, say, $T_s=3$ seconds. We shall consider $T_s=3$, 0.5, and 0.1 s. Kill time Jr^2/B then becomes T_s+Jr^2/B, which is equivalent to replacing r^2 by (r^2+BT_s/J) in the calculation of M. We then have

$$M=\pi s(BT_0/J)\ln\left[\frac{(U^2+BT_s/J)}{(h^2+BT_s/J)}\right] \quad (7)$$

Round Earth. The horizon (tangent plane to the Earth at the booster launch location) intersects the satellite constellation sphere at a distance

$$H=[(E+h)^2-E^2]^{1/2} \quad (8)$$

Satellites beyond that distance are below the horizon and shielded from the booster at low altitude. For example, $H=1.94$ Mm for $h=300$ km, far less than the upper limit of the integral for calculating M in the flat-Earth case, for which U exceeds 11 Mm. Apart from small effects relating to the somewhat reduced range to a satellite on the basing sphere at ρ, the spherical distribution of satellites can be taken into account. With

$$U'\equiv\min[(U),(H)] \quad (9)$$

Equation (7) becomes

$$M=(\pi sBT_0/J)\ln\left[\frac{(U'^2+BTs/J)}{(h^2+BT_s/J)}\right] \quad (10)$$

or, for the normal horizon-limited case,

$$M=(\pi sBT_0/J)\times\ln[1+2hE/(h^2+BT_s/J)] \quad (11)$$

In order to use the satellites to best advantage, we maximize M with respect to h. The logarithm is maximum when the argument is maximum, which for the horizon-limited case, yields the criterion

$$h^2=BT_s/J, \quad (12)$$

For this optimum altitude, we then have

$$M=(\pi sBT_0/J)\times\ln[1+E(BT_s/J)^{-1/2}] \quad (13)$$

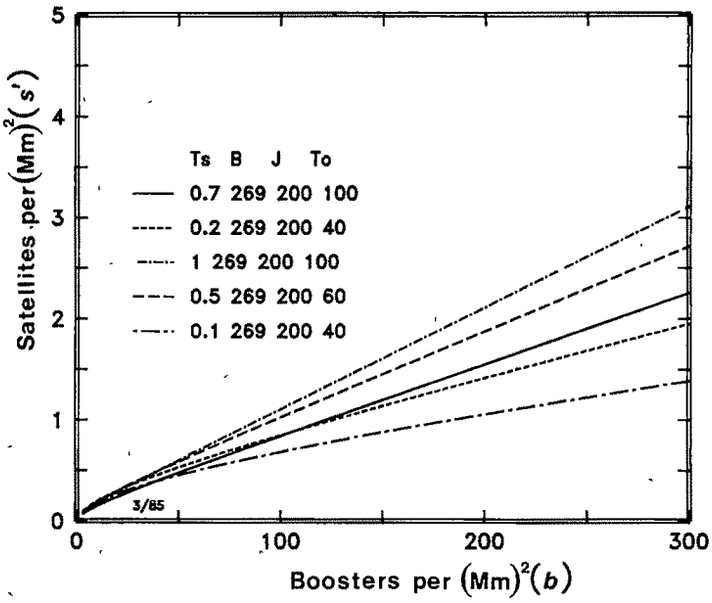

Fig. 3 Shorter retarget times T_s than in Fig. 2 are modelled here. Note that the "square-root scaling"[3,4] is confined to low booster density and is replaced by a linear relationship at high booster density. Satellite density s' exceeds the greater of bT_s/T_0 and $(Jb/2\pi BT_0)^{1/2}$. Thus a model which is inapplicable because of geographic distribution also fails to give favourable square-root scaling at large threats when finite retarget time is considered

valid so long as $H^2<U^2$, or so long as $2E(BT_s/J)^{1/2}+(BT_s/J)<U^2$. For $B=269$, $J=200$, this condition is satisfied up to $T_s=9.8$ seconds for $T_0=40$ and $T_s=17.5$ s for $T_0=100$. The results for the numbers of boosters killed are plotted in Fig. 1.

Distributed boosters

We now turn to the question of the validity of the claimed "square-root scaling" of satellite density with increasing booster density. To calculate the constellation densities to destroy boosters distributed uniformly (with density b) over a plane, we assume satellites on a regular triangular (hexagonal close-packed) lattice at altitude h, with nearest-neighbour satellite spacing $2R$. To each satellite is assigned the task of destroying every booster in its own circle of responsibility of radius R (which strictly is a hexagon whose area is 10.3 per cent greater than that of the intended circle). The capability of each satellite is exhausted when the sum of the times taken to kill each booster (including retarget time) exceeds the available engagement time T_0. For a given booster density b, we calculate the time T required for a satellite to kill its "own" boosters, which is a function of the parameters b, J, h, R, B and T_s. If the laser parameters B and T_s are fixed, we maximize constellation capability with respect to h for a given satellite density $s\equiv1/\pi R^2$ and thus determine b, which gives a point on the b–s curve of booster density against satellite density (or number). If $t(r)$ is the time to kill a booster at distance r, and ρ is now the radial coordinate on the ground, with origin at the sub-satellite point, the time required to kill all boosters is

$$T\equiv\int_{\rho=0}^{\rho=R}t(r)b2\pi\rho\,\mathrm{d}\rho \quad (14)$$

The integral extends over all the boosters within radius R of an individual satellite. With $t(r)=T_s+Jr^2/B$ and $a\equiv r^2+(BT_s/J)$, the time T becomes $\pi Jb/B\int a\,\mathrm{d}a$ between limits which are the extreme values of a (differing by R^2), which leads to the result

$$T_{\min(h)}=(2\pi Jb/B)(R^4/4)\times[1+(2/R^2)(BT_s/J+h^2)] \quad (15)$$

This time is a minimum at $h=0$, whence

$$T_{\min(h)}=(2\pi Jb/B)(R^4/4)\times(1+2BT_s/JR^2) \quad (16)$$

and

$$T_0=(Jb/B)(\pi R^2)^2(2/4\pi)\times(1+2BT_s/JR^2) \quad (17)$$

$$s^2=(Jb/BT_0)(1/2\pi)\times[1+(2\pi T_sB/J)s] \quad (18)$$

Satellites cannot be in orbit at zero altitude, so that s defined by this quadratic equation will again be an underestimate. The equation determines the satellite density s required to cope with an infinitely extended booster distribution of density b.

A more flexible assignment of targets would require fewer lasers, but we take our restrictive assignment scheme as a prerequisite (but not a sufficient condition) for a claimed square-root scaling, in order

to explore the actual scaling law. The solution of the equation is

$$s = (T_s/T_0)(b/2) \times\{1+[1+(1/b)(2/\pi)(T_0J/BT_s^2)]^{1/2}\} \quad (19)$$

If $b \gg b^* \equiv (2/\pi)(T_0/T_s)(J/BT_s)$, then $s \simeq bT_s/T_0$ and is linear in booster density. For the parameters assumed, our $b^* = 5.3$ per $(\mathrm{Mm})^2$ is far below the existing 140 per $(\mathrm{Mm})^2$ density of Soviet ICBMs, and the number of satellites required is linear in the number of boosters deployed. In terms of satellite density, $(2\pi T_sB/J)$ is 25.36 for satellite retarget time $T_s = 3$ seconds. Thus the second term in equation (18) dominates the first for $s > 0.04$ satellites per square megametre. Much weaker satellites, or shorter retarget time, or tougher boosters will be required to obtain "square-root scaling," even for infinite distributions of boosters and satellites[7,8].

Equations (18) and (19) teach us that "square-root scaling" can enter only at low satellite density or low booster density, respectively. But a stronger inference can be drawn from Equation (19) regarding the scaling of numbers of satellites of given characteristics versus numbers of boosters of infinite extent. Clearly, the asymptotic behaviour for large numbers of boosters is $s = bT_s/T_0$—each local satellite destroying a booster each retarget time, for the entire burn or engagement time. But Equation (19) tells us that satellite numbers are always greater than that given by the asymptotic formula, and in the linear range this residue of square-root scaling requires an additional satellite density $s_+ = J/2\pi BT_s$. Thus we know that even on the assumption of widely deployed boosters, the required local density of satellites is at least the local density of boosters multiplied by T_s/T_0, and the ratio of the cost of the satellite constellation to the cost of the booster constellation exceeds

$$(C_s/C_b) \times (T_s/T_0) \times (4\pi E^2/yA) \quad (20)$$

where C_s is the cost of a satellite, C_b the cost of a booster, and A the area over which the boosters are deployed. Adopting the proposed[7,8] assignment strategy that satellites should be restricted to shoot within their circles of responsibility (as required for square-root scaling), and assuming the deployment area to be 10 square megametres and a satellite concentration factor $y = 3.1$ from optimum orbits, satellite numbers are $16T_s/T_0$ times the number of boosters. With 3-second retarget time and 100-second engagement time, one satellite must be deployed for every two boosters, and the defense would be overcome by a cheaper offensive deployment if a booster cost less than half the price of a laser battle station.

Since the laser must have been launched into orbit by a rocket, and weighs far more than the ICBM payload, and because lasers must be deployed over an area very much larger than the booster deployment area (to which active lasers are limited by the assignment strategy needed for square-root scaling), boost-phase intercept can hardly be achieved cost-effectively by satellites armed with powerful lasers. Furthermore, for non-zero retarget time and for reasonable satellite and booster characteristics, satellite numbers are proportional to booster density even for infinitely extended booster deployment. Because satellites are assumed to shoot only at local boosters in the distributed launch case, there appears to be little difference between the planar constellation and round-Earth results for distributed launch, although the smaller values of S' in Table 1 would be increased by recognition of horizon limitations which impose $h > 0$.

With the simplistic assignment of satellites to kill widely distributed boosters in their immediate vicinity, Equation (18) shows a number of satellites linear in booster density except for near-zero retarget time, and then only for satellite altitude zero or scaled with satellite separation, and also only for low booster densities. According to Equation (19), large booster density, short burn time, reduced booster hardness, enforce linear scaling; while poor laser brightness and short retarget time are conducive to square-root scaling. Figure 2 and the columns in Table 1 labelled s'' and S'' demonstrate near-linear scaling for many cases of interest with distributed boosters.

This rather primitive assignment of satellite resources is in fact far from optimum in some of the cases considered here, and since a defensive system will be two decades or more in evolution, it is realistic to consider the satellite numbers required to overcome a more responsive threat—the clustered launch of smaller missiles.

The last two columns in Table 1 present the satellite density and numbers required to handle the indicated booster threat for launch of boosters from an area some hundreds of km diameter. We assume 25 MW of 2.7 micrometre laser light; 10-m diameter perfect optics; retarget time T_s of 0.1, 0.5, or 3.0 seconds as indicated; engagement duration T_0. For concentrated launch, the required number of satellites is proportional to the number of boosters.

Figure 3 demonstrates that only for retarget time of 0.1 second is there such a thing as "square-root scaling" at existing booster numbers. Furthermore, Table 1 and Fig. 1 illustrate that the Soviets have a far more effective response than to build additional silos distributed over their vast territory—namely to cluster them in a region 1,000-km diameter, or so, and to pay the modest additional cost to shorten burn time to 40–50 seconds. This would also negate boost-phase intercept by satellites carrying X-ray lasers, particle beams, and by any pop-up weapon. Such a response would ensure that boost-phase intercept could not meet the requirement stated for the US Government on 20 February by P. H. Nitze that it "be cheap enough to add additional defensive capability so that the other side has no incentive to add additional offensive capability to overcome the defence."

Nuclear collisions at intermediate energies: achievements and prospects of GANIL

Claude Détraz

GANIL, Boite Postale 5027, 14021 Caen Cedex, France

At energies of tens of mega-electronvolts per atomic mass unit, nuclear collisions exhibit phenomena more complex than the essentially collective behaviour at lower energies or the more individualistic nucleon interactions observed at much higher energies. This intermediate regime is being uniquely explored at the French national heavy-ion accelerator GANIL.

THE French facility for heavy-ion physics, GANIL (Grand Accélérateur National d'Ions Lourds), has been operating since 13 January 1983. The first beam from this accelerator, which uses a series of three cyclotrons to bring the velocity of ionized atoms to about one third of the velocity of light, had been obtained two months earlier, in November 1982. From the start, GANIL was thought of as a national facility. This had two consequences: first, the formation of a very able team of engineers and technicians from all French laboratories; second, the choice of an accelerator that would represent a significant improvement on anything previously built in France, but which was within reach.

The nature of the beams to be accelerated and the type of the accelerator were decided in 1972–74. At that time, heavy-ion research had just established itself in the study of atomic nuclei. For some years, many physicists had considered it to be a backwards step from the precise and successful analysis of discreet nuclear states that the accelerators of light ions, such as protons and α-particles, had provided. Massive projectiles, such as the ions of carbon, calcium and heavier elements, with poor energy resolution, were described by some as awkward tools for the study of the subtle quantum structure of nuclei—not much better, perhaps, than the use of boxing gloves to put thread through the eye of a needle. Yet, in about 1970, it was clear that nucleus–nucleus collisions, as made possible by heavy-ion beams, were unique means of studying the collective coherent behaviour of nuclei. New phenomena were discovered and the lexicon of nuclear physicists had to be expanded to include new phrases such as dissipative phenomena, temperature, time evolution and friction, which undoubtedly reflected increasing knowledge about nuclei. French groups had been particularly active in this field, with a major part being played by the ALICE accelerator in Orsay.

What was the next step? One problem arose from the mismatch between the turnover time for an experiment, typically 6 months to 2 years, and the time needed to design and build a heavy-ion accelerator, typically 5–10 years (constructing an accelerator for particle physics takes about the same time but experiments last several years. At the other extreme, in most fields of physics, the turnover time of experiments is measured in months, as in nuclear physics, but the equipment is usually lighter and can be transformed at a similar rate). Hence, at the beginning of the 1970s, French nuclear physicists had to design an accelerator for the 1980s and 90s while hoping that the next experiments woud help to elucidate the mechanisms of dissipation of excited nuclear systems within the next year. But choices had to be made, and three orientations were agreed upon: (1) The new accelerator had to accelerate ions up to velocities of 100 MeV AMU^{-1} with no provision for extending that range further. (2) The structure of the accelerator would consist of a small compact injector cyclotron followed by two large separated-sector cyclotrons operating in series (Fig. 1). Other possibilities were discarded. A linear accelerator would have opened up a regime field not very different from that well explored by GSI Darmstadt. Cryogenic cyclotrons would have proved difficult to design and operate safely, a risk that a relatively small community could not afford. The coupling of an ion source of high ionization ability with a synchrotron would, it was felt, limit the intensity of the beams and rely too heavily on the overcoming of technical problems not then solved. The choice made seemed to represent the best compromise between innovation and security. (3) The new laboratory had to be a national facility, therefore all agencies and laboratories had to contribute in manpower and financially to ensure the successful completion of the GANIL programme.

Some 30 articles dealing with experimental work done at GANIL have been published so far. They are systematically compiled and discussed in *Nouvelles du GANIL*, published bimonthly and sent on request to all interested scientific institutions.

Among the general papers (unpublished) dealing with GANIL nuclear physics are:

M. Lefort *Lectures to the Cargese Summer School* 'Heavy-Ion Collisions from Nuclear Collective Motion to Quarks' (September 1984; preprint IPN-Orsay IPNO-DRE-84-33).

B. Tamain *Lecture to the 16th International School on Nuclear Physics* (Mikolajki 1984; preprint LPC Caen 84-03).

C. Detraz *Mt Fuji Symposium on Heavy-Ion Physics* 'First results from GANIL' (Tokyo, August 1984).

Intermediate energy physics

Next, I discuss the reasons that determined the choice of the beam energies available at GANIL. The idea was to study nuclear collisions in an energy range where a transition between two regimes occurs. Figure 2 shows the domain available with GANIL in comparison with other existing or projected accelerators. At energies of several tens of MeV AMU^{-1} the processes at work when two nuclei collide should change markedly. I will address four such arguments.

First, the wavelength λ associated with a nucleon of a projectile with an energy of say 5–10 MeV AMU^{-1}, available with major cyclotrons and tandems, is much larger than the mean distance d between two nucleons of the target nucleus. Thus, the incoming nucleon will 'see' (that is, interact with) several target nucleons. The collision process will then seem to be essentially collective. In the 1960s and 70s one could thus study the fusion process in which the two colliding nuclei fuse into a single excited nuclear system, and the so-called deep inelastic collisions where a temporary binuclear system is formed before the two partners separate again. The latter, an unexpected process, offered significant new information on the collective properties of nuclear matter and even, at a more elementary level, on the mechanisms that allow the propagation and dissipation of energy and angular momentum.

At the other extreme, say at 1,000 MeV AMU^{-1} energy, the situation is clearly the opposite, λ becoming smaller than d. The reaction mechanism results from the superposition of nucleon–nucleon interactions. The degree of overlap of the two colliding nuclei determines the dominant behaviour. In central collisions complete explosion is observed, whereas in peripheral ones a

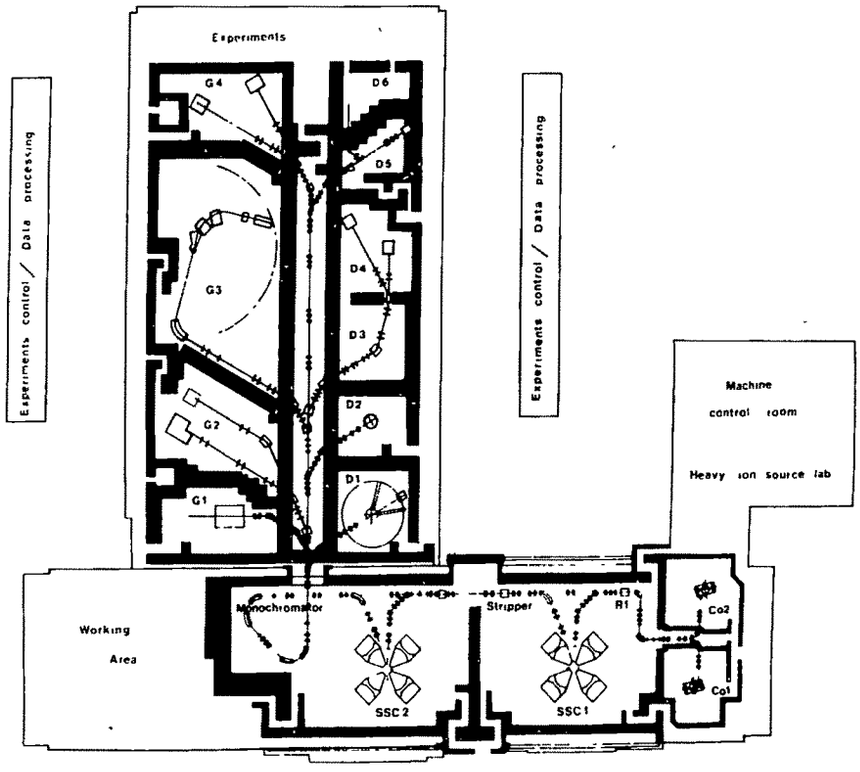

Fig. 1 Layout of the GANIL accelerating system, consisting of one compact cyclotron injector and two large separated-sector cyclotrons (SSC). A thin carbon-foil stripper increases the charge stage of the accelerated ion before entering the second SSC. An α-shaped magnetic analyser selects the momentum of the accelerated particles before the beam is transported to the various experimental areas.

participant zone, highly excited and emitting many fast nucleons, can be distinguished from the spectator zones corresponding to the non-overlapping parts of the nuclei. Despite their very low beam intensity, those high-energy machines that could accommodate heavy ions, such as the Bevalac in Berkeley and the synchrophasotron in Dubna, confirmed this overall picture.

Second, the quantum nature of the two colliding nuclei means that the interaction of two of their nucleons, which are fermions, is only possible if they can be scattered into unoccupied discrete states. Because all the quantum states below the Fermi level are occupied in both nuclei, this requires that the energy available in the nucleon–nucleon collisions be large enough to promote these nucleons into highly excited states. In terms of velocity instead of energy, individual nucleon–nucleon interactions play a significant part in the nuclear collision only if the relative velocity of the nucleons is larger than the Fermi velocity, which is equivalent to ~35 MeV AMU^{-1}.

Third, the velocity of sound in nuclei can be calculated from what is already known about the elementary modes of excitation of nuclear matter. An elementary local perturbation of the wave function of nucleons propagates with a velocity of ~30 MeV AMU^{-1}. When the relative velocity of colliding nucleons is far below this value, the perturbation induced can be distributed all over the nuclear system during collision time. In other words, thermalization can be achieved but above this value it is impossible and thus the nucleons ejected remain very energetic.

Fourth, it has long been known that two nuclei can fuse only if the total energy transformed into excitation energy of the compound nucleus is not too high. Above an average value of 8 MeV per nucleon, the nucleons become unbound and the nucleus is then beyond its boiling point. Such a situation is reached in a collision of nuclei with similar masses when the bombarding energy in the laboratory reference frame is ~30 or 35 MeV AMU^{-1} but never in the few experiments performed above 100 MeV AMU^{-1}.

First results from GANIL

The long-term goals of the research programme at GANIL proceed from the above arguments. The energy available allows us to explore the transition region where the nuclei evolve from a coherent state to a collection of individual nucleons. One can formulate the regime in terms of a thermodynamic phase transition. The nuclear system formed in low-energy collisions can be described by collective variables; it exhibits a high degree of coherence and is not unlike a liquid. The concepts of viscosity, temperature, friction and the shape parameters seem to be useful. In high-energy collisions, the system behaves like an assembly of loosely interacting individual nucleons, rather similar to a gas.

The GANIL energies encompass the transition region. How does such a phase transition proceed and what phenomena occur when the nucleus looses its coherence? To observe and analyse these features is the primary experimental objective of the accelerator. More fundamentally, perhaps, these observations should allow physicists to address the following question: out of the very large number of degrees of freedom of the system formed by the excited assembly of nucleons, can the few relevant parameters that describe its structure and evolution be identified? This question defines a basic problem in statistical physics. The excited piece of nuclear matter formed in the collision has very distinctive features: it consists of a finite number of fermions, carries a high internal energy and is governed by the laws of quantum mechanics. Present-day statistical mechanics have not answered to this problem. It cannot provide parameters to derive the relevant variables nor laws to describe the evolution of such a system. These answers must come from nuclear physics itself.

Yet the experimental information obtained from these nuclear collisions seems hopelessly complex. A large variety of nuclear fragments with a wide energy spectrum are emitted at all angles and an accurate description of the actual reaction mechanism must be obtained from this mass of information. In heavy-ion physics, the additional wide variety of target, projectile and energy combinations adds both to the amount of information and to the difficulties of its interpretation.

The search for a thorough description of nuclear matter at the limits of its coherence, which, as stated above, is the goal of GANIL physics, could then start from hundreds of arbitrarily chosen points of view. One could say: let us investigate whether fast oxygen fragments are emitted forwards in coincidence with isotopically emitted α-particles, when argon and uranium nuclei collide. One would certainly observe such events with a probabil-

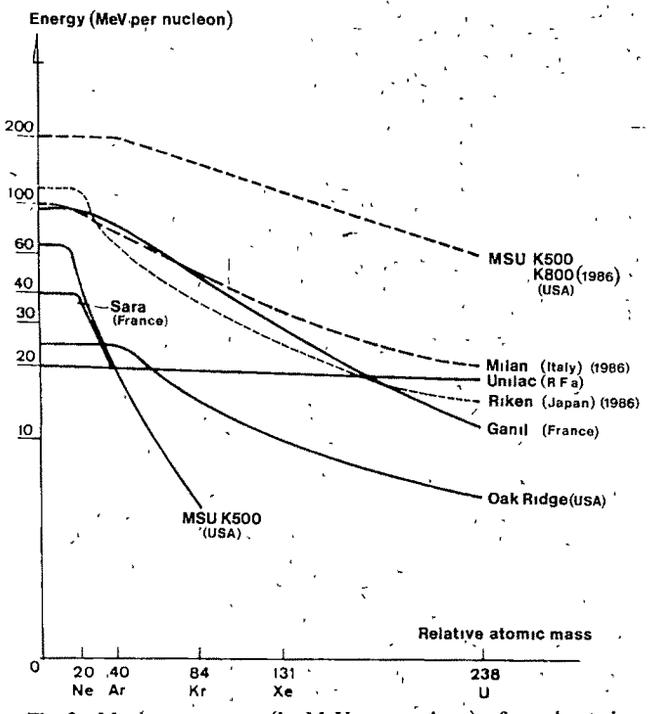

Fig. 2 Maximum energy (in MeV per nucleon) of accelerated ions from several accelerators, as a function of the atomic mass of the ion. Solid lines refer to operating facilities and dashed lines to projects.

ity that could be measured, then move to another event. However, little insight would emerge from such a random approach.

At GANIL, physicists started from known facts. As stated above, they had reached a detailed understanding of the dissipitative phenomena that occur in lower energy collisions. Similarly, the well-documented fragmentation process observed at high energy could be used as a reference. These initial points of reference have been used extensively since the first experiments of January 1983.

In dissipative interactions, the two colliding nuclei are linked for a time, rotating around their centre of mass and progressively equilibrating the various parameters that describe their respective structure, such as the ratio of neutrons to protons (N/Z), the energy and the angular momentum. Of these parameters, the one that equilibrates fastest is the N/Z ratio. This means, for instance, that a ^{28}Si projectile (14 p, 14 n) interacting with a heavy target such as ^{208}Pb, which has a large neutron excess (82 p, 126 n), will emerge as a neutron-enriched fragment. Such an equilibration occurs in $\sim 2 \times 10^{-22}$ s. It seemed of interest to see whether such a fast equilibration process would still occur at higher incident energies, that is, for shorter interaction times.

An unambiguous answer was achieved with incident beams of ~40 MeV per nucleon. Although the interaction times are long enough to accommodate the fast N/Z equilibration process, the average value of the N/Z parameter of the emitted fragment was found not to be influenced by the target. Rather, it closely reflects the value of the projectile, hence pointing to a fragmentation process. The forward-emitted nucleus results from the breaking of the projectile in the field of the target. No binuclear state is formed that would allow for some equilibration of the parameters. It took only two weeks to obtain the expected, although reassuring, information that the GANIL energies were high enough to observe the transition from low energy to high energy processes; it took a few months to confirm it with other projectile–target systems. Since then, however, a large amount of beam time has been necessary to qualify the observation that, at energies as low as 40 MeV per nucleon, collisions result in fragmentation.

Several well-established properties of the forward-emitted fragments are incompatible with a pure projectile-fragmentation mechanism. First, it was observed that the isotope distribution of the fragment (that is, the variation of the yield of isotopes of a given element Z with their mass A), depends somewhat on the nature of the target. More precisely, the more neutron rich the target is, the more probable is the emission of a neutron-rich fragment. Hence, the so-called fragmentation of the projectile includes some exchanges between the two colliding nuclei, a property obviously at variance with a pure fragmentation process. Second, some of the forward-emitted fragments actually gained one or two neutrons or protons as compared with the incident projectile, which again is incompatible with pure fragmentation. Finally, the energy characteristics of these fragments differ from those observed at higher energy. Instead of being centred around the velocity of the projectile, as expected and observed for fragmentation products, the velocity spectrum extends to lower values, giving evidence for the importance of relaxation processes during the interaction.

This accumulation of facts for and against a model of a reaction discussed here must be seen as an example of the approach pursued at GANIL during the first one or two years. Similar studies have been performed on the fate of central collisions. The ability of the two nuclei to fuse and the possibility that the resulting nucleus absorbs all the momentum carried by the projectile have been studied for different systems and for various energies.

This first stage of research is basically complete, at least for projectiles no heavier than krypton. The main facts are collected and published, but, at this stage, the conclusions remain ambiguous and difficult to formulate. This should not be surprising. Again, the results have been interpreted within the framework of known reaction mechanisms. Physicists have been looking for footprints they could identify and so they ascribe the results to the contributions of several mechanisms. This situation will not last: at the limits of nuclear coherence, when the internal motions inside nuclei and the relative motion of the two colliding nuclei carry similar velocities, new processes, as yet unknown, will provide a simpler description. So far we approximate them through conceptually understood mechanisms described for other situations. But the procedure that helps us describe the apparently complex properties of the system should not be mistaken for the as yet undefined new set of original concepts, effective variables and simplifying models.

Future research

We have now entered a new phase of development along the lines discussed above. Both experimental and theoretical physicists (perhaps not as readily distinguishable in heavy-ion physics as in other fields of nuclear physics) have concentrated on examining systematically the relevance of the variables commonly used in the light of the first results. For example, can we define a temperature and find unambiguous ways to measure it in the systems under study? This new phase should bring us closer to selecting the relevant parameters.

Simultaneously, the need to move from inclusive measurements to more exclusive ones results from the gross features of reactions already observed. For instance, when one observes a so-called fragment of an argon projectile after collision with, say, a nickel nucleus, which other fragments or particles emitted during that process have gone unobserved; at which angles were they emitted; and how much of the initial energy did they carry?

These questions call for large multidetectors with an ability to detect and measure fragments in all directions. For each single collision, several hundreds of parameters must be read to collect all the information gathered by all the detectors. It would have been unrealistic to begin with such capabilities: how could intelligent use of 700-dimensional information be made? Now that the basic features of the reactions have been observed, such second-generation studies become not only legitimate but necessary. These new experiments have already started at GANIL, where >200 parameters can be read. For example, two-proton interferometry is used to study the size of the emitting hot zone of the so-called participant nucleons described earlier.

This method is very similar to the two-photon interferometry used to measure the size of stars.

We are ready to develop detectors and data-acquisition that can measure up to 700 parameters. I do not believe that this implies a blind jump into experimental megalomania. This programme is extrapolated from systems already operational and derives naturally from results obtained by physicists already involved in understanding the dynamics of the collisions.

Here, I have not given a full review of all the results obtained and all the ideas advanced to understand them, but have attempted, by the use of examples, to outline the means by which original properties of nuclear matter in the transition energy region opened by GANIL are being investigated. Indeed, this is the major challenge, yet the potential of high-intensity medium-energy heavy-ion beams for nuclear physics is, in my view, already well established by some of the results obtained. The use of projectile fragmentation to observe new neutron-rich isotopes through a triple-focusing magnetic analysis system allows us to extend the limits of known nuclei by one or two isotopes: ^{23}N, ^{29}Ne and ^{30}Ne were seen in the first attempt. The high excitation energy that can be transferred to nuclei has allowed the observation of high-lying excited states of simple configuration, probably multi-phonon excitation, of up to ~70 MeV. The cooperative creation of pions below the nucleon–nucleon threshold has been observed at the lowest energy ever.

Those are only some examples of the results obtained. In the coming years, several new machines at Catania, East Lansing (Michigan), Tokyo, Lanzhou and elsewhere will achieve the performance of GANIL. This interest reflects the novelty and scientific importance of a wide field now opened. One can anticipate that major developments in the understanding of the properties of nuclear matter will result from such a large-scale effort. The challenge for the GANIL physicists will be to play a leading role in the emergence of the new ideas.

A quantum potential approach to the Wheeler delayed-choice experiment

D. J. Bohm, C. Dewdney* & B. H. Hiley

Department of Physics, Birkbeck College, Malet Street, London WC1E 7HX, UK

We apply the quantum potential approach to a 'delayed-choice' experiment considered by Wheeler and show that there is no need to conclude that the past has had no existence except insofar as it is recorded in the present.

WHEELER[1] has given a detailed description of several possible types of 'delayed-choice' experiment designed to show that, according to the quantum theory, the choice to measure one or another complementary variable at a particular time can apparently affect the course of events for considerable periods of time before such a decision is made. Wheeler interprets this using Bohr's principle of complementarity and his emphasis on the phenomena and experimental arrangement as forming an indivisible whole. He concludes that "no phenomenon is a phenomenon until it is an observed phenomenon", so that the "Universe does not 'exist out there' independently of all acts of observation. It is in some strange sense a participatory Universe. The present choice of the mode of observation ... should influence what we say about the past ..., the past is undefined and undefinable without the observation."

We discuss here the same question raised by Wheeler using a different approach that is completely consistent with quantum mechanics, namely the quantum potential approach[2,3]. (This question has also been treated by Bell[4] who came to a similar conclusion emphasizing different aspects of the problem.) Our approach agrees with Wheeler in concluding that this is a participatory Universe but differs in that the whole process, past and present, is treated as uniquely determined in itself, and not merely by what we are led to say about it through our observations. That is to say, there is a definable and defined overall process that includes both the observer-participator and the rest of the Universe in one undivided whole. Thus, we concur that the behaviour of the Universe is not independent of acts of observation, but also add that the past has had an existence independent of these acts.

Delayed-choice experiment

To bring out the difference between Wheeler's approach and our own through the quantum potential model, we will first re-examine one specific experiment described by Wheeler (the generalization to other more complex experiments is straightforward).

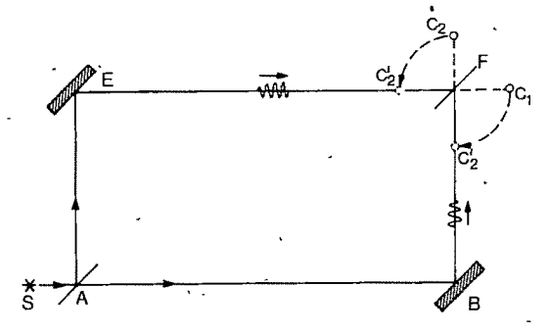

Fig. 1 Schematic view of the delayed-choice experiment for photons passing through a half-silvered mirror at A. Counters C_1 and C_2 can be moved into positions C_1' and C_2'

Two photodetectors are mounted so that they can be moved easily and quickly either to positions C_1 and C_2 or to the positions C_1' and C_2' (Fig. 1). Suppose a single quantum of electromagnetic energy passes through a half-silvered mirror at A Then, with the detectors in positions C_1 and C_2, the relative counting rates will determine the phase difference between the two routes. With the counters in positions C_1' and C_2', one can infer which route the photon takes. Thus, we can choose whether to perform either a two- or a single-beam interference experiment by the choice in the positions of the two detectors. Furthermore we can make this choice some time after the original photon has entered the apparatus but before it reaches F, thus giving rise to a delayed-choice effect. It is as if we could determine by our choice whether the photon has travelled along both routes or only one route.

It should be emphasized that Bohr has already pointed out that, in his view, the notion of the route that the photon or

* Present address. Laboratoire de Physique Théorique, Institut Henri Poincaré, 11 Rue Pierre et Marie Curie, 75231 Paris Cedex 05, France.

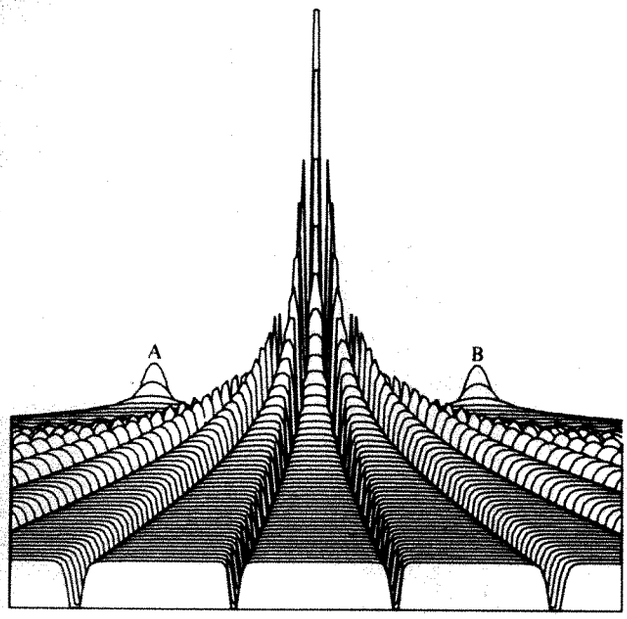

Fig. 2 Quantum potential for the two-slit experiment. The two slits are at A and B while the interference fringes appear in the foreground.

particle travels along has no meaning. Indeed, he[5] cites this very experiment, and in commenting on it, states, "it is just arguments of this kind which recall the impossibility of subdividing quantum phenomena and reveal the ambiguity in ascribing customary physical attributes to atomic objects". He further states that "all unambiguous use of space-time concepts in the description of atomic phenomena is confined to the recording of observations which refer to marks on a photographic plate or to similar practically irreversible amplification effects like the building of a water drop around an ion in a cloud-chamber".

The very idea of a 'micro-reality' (such as photons, electrons) that exists in some sense independently of the experimental context is thus denied. To be consistent with Bohr's point of view, the discussion should be solely in terms of what is observable and no attempt should be made to discuss paths of particles that would provide an explanation or account of how the experimental results obtained at successive times are connected.

Heisenberg[6] has a view similar to that of Bohr in many respects but different in that he argues that it is meaningful to talk about an orbit after an observation has taken place. In fact he writes "... the 'orbit' comes into being only when we observe it". For example, if an electron is observed at A and then later at B, one could say that the orbit went from A to B but the subsequent motion of the electron beyond B would be unpredictable. A further measurement at C might show that it actually was, but then the movement beyond C would be unpredictable. Thus, the concept of an orbit has a meaning only in the past of the act of observation.

Note, however, that there is no way to verify that the inferred trajectories were the actual orbits by additional experiments. Thus, it would be quite possible that the particle did not follow a straight line between A and B or, indeed, that there was no particle at all in the intermediary space and time. It would be equally consistent to assume that the particle appears only in the act in which it is made manifest. Thus, this discussion of the paths of particles has only the function of giving an explanation of how the phenomena are connected and is not capable of being verified experimentally.

Wheeler, of course, agrees basically with Bohr's point of view, but he has used Heisenberg's way of discussing this situation to show that the assumption that the past did exist independently of present observation leads to absurdities. This he regards as a support for his notion "that no phenomenon is a phenomenon until it is an observed phenomenon". In doing this, Wheeler does not use specific particle trajectories, but instead uses wave-packets to connect the present to the past. When the particle does not show interference effects, this packet corresponds approximately to a somewhat indistinctly determined trajectory, but when the experimental arrangement allows interference, the connection between the present and the past is made by the two packets acting together.

The approach of Bohr and Wheeler is possible in the sense that it is consistent. We feel, however, that the quantum potential approach, which we will outline below, treats the whole question in a more intelligible way. Here it is consistent to say that the past existed in a unique way that does not depend on what happens in the present. Nevertheless, some of the key points raised by Wheeler are retained but are comprehended differently.

Quantum potential approach

A consistent treatment of the electromagnetic field using the quantum potential approach is possible, and the outline of such a treatment has indeed already been elucidated[2,7]. However, the details are rather complicated and would perhaps obscure the main point. Therefore, we confine our attention in this paper to the interference of particles such as electrons and neutrons, for which we can apply the quantum potential approach in a straightforward way[8]. Indeed, delayed-choice experiments of the type suggested by Wheeler, but using neutrons, have actually been proposed by several authors[9,10].

We begin by first writing the wavefunction in standard polar form

$$\psi(\boldsymbol{r}, t) = R(\boldsymbol{r}, t) \exp\left[\frac{iS(\boldsymbol{r}, t)}{\hbar}\right] \tag{1}$$

From Schrödinger's equation it follows, writing $P = R^2$, that

$$\frac{\partial P}{\partial t} + \nabla \cdot \left(\frac{P \nabla S}{m}\right) = 0$$

and

$$\frac{\partial S}{\partial t} + \frac{(\nabla S)^2}{m} + V + Q = 0 \tag{2}$$

where Q is the quantum potential given by $Q = -(\hbar^2/2m)(\nabla^2 R/R)$ and the velocity is assumed to be given by $V = \nabla S/m$.

To interpret these two equations, we regard, say, a neutron as consisting both of a particle, which has a definite position and a definite momentum (and therefore a definite trajectory), and a field which is inseparable from the particle. The field is just the wavefunction as expressed through the two real fields R and S. It satisfies the Schrödinger equation which determines the time behaviour from the initial conditions.

Before proceeding further, we stress again that the particle and the field are indissolubly linked and we make no assumptions as to why or how this arises. Here we are simply attributing to the field those properties that are necessary to account for the quantum phenomena. To explain the origins of this field will require us to go deeper and make new physical assumptions of the type used by Bohm and Vigier[11] or by Cufaro Petroni and Vigier[12] or, indeed, some other appropriate ideas. It is not necessary to address such questions here as they are not relevant to the principles we wish to discuss. As a result, we use concepts such as 'wave-packet' that are applicable in the one-body case, but cannot be generalized in such a simple way to the many-body system which would require a field in the multi-dimensional configuration space. Therefore, such concepts are simply a convenient way of dealing with the phenomena and should not be taken as a definitive description of the nature of reality at this level.

Returning now to the main discussion, it is evident that equation (2) is similar to the Hamilton-Jacobi equation but it differs in that it has the additional quantum potential term Q, which leads to the suggestion that the particle follows an orbit different from the classical one. This difference is the result of

the quantum potential and is one of the major factors accounting for the quantum properties of matter.

To account for the rest of the quantum properties of matter, we must first consider the single valuedness of the wavefunction that leads to a kind of modified Bohr-Sommerfield quantum rule

$$\oint \nabla S \cdot \mathrm{d}x = nh \tag{3}$$

(The difference from the Bohr-Sommerfield quantum rule is that, in the former, S is obtained from the classical Hamilton-Jacobi equation, whereas here it is obtained from the quantum Hamilton-Jacobi equation (2).)

Finally, we have to interpret equation (1), which is evidently a conservation equation. We can do this consistently by assuming a statistical ensemble of similar systems all having the same wavefunction ψ. We further postulate that P is the probability distribution in this ensemble. This postulate is consistent in the sense that if it holds at the time $t = 0$ the conservation equation will guarantee that it will hold at all times.

Wigner[13] has objected to this approach by arguing that Q depends on R and that R refers only to the ensemble of systems. He concludes that it is unreasonable to have a theory in which the individual depends on the ensemble. Our answer to this criticism is that we do not primarily regard R as referring to the ensemble but rather as part of a field that belongs to the individual system as much as the particle does. The major effect of the field is to produce the force derivable from the quantum potential. But we have shown that the field can also describe the probability in an ensemble of systems that have the same field; that is, that have the same wavefunction except for a constant factor. This requires, of course, a further special assumption on the statistical ensembles. But the consistency of this assumption depends on the properties of the individual systems that make up the ensemble and, therefore, the individual does not depend on the ensemble but the ensemble depends on the individual in the way that is customary, for example, in classical statistical mechanics. The only new feature is that both quantum potential and probability are obtained from the same field R.

As an example, we give here the two-slit interference experiment[14]. We assume as an initial condition an ensemble of particles each having a plane wave that passes through a pair of slits. After passing through the slits, the two waves interfere and produce a very complex quantum potential shown in Fig. 2. At some distance from the slits, the form of this potential is that of a set of plateaus separated by a set of deep valleys. Figure 3 shows the paths of the particles in the ensemble. Clearly the net effect of the potential is to bunch the trajectories so as to produce the pattern of the well-known interference fringes in the statistical ensemble.

To understand this result, it is crucial to note that the quantum potential is not changed when the wavefunction is multiplied by an arbitrary constant, that is, that the quantum potential is determined only by the form of the wavefunction and not by its magnitude. This means that the effects of environmental features such as the slits can be felt by the particles at long distances. This is not in itself a form of non-locality because the effect is propagated locally via the wavefunction to which Schrödinger's equation applies. However, it represents the possibility that the behaviour of the particle cannot be separated from the whole context of the environment which is involved, for example, through a determination of the experimental conditions. We also add here that through such a dependence on the environment, the particle does not necessarily travel in a straight line at constant speed in what appears to be empty space. Rather, as shown in Fig. 3, it may have a complicated and irregular motion.

Let us now proceed to use this approach to account for Wheeler's[1] experiment. A detailed treatment using the quantum potential would be more complex than that required for the two-slit experiment described above, but the basic principles involved are the same. Therefore, we can use the approach to account in a general way for the experiment shown in Fig. 1.

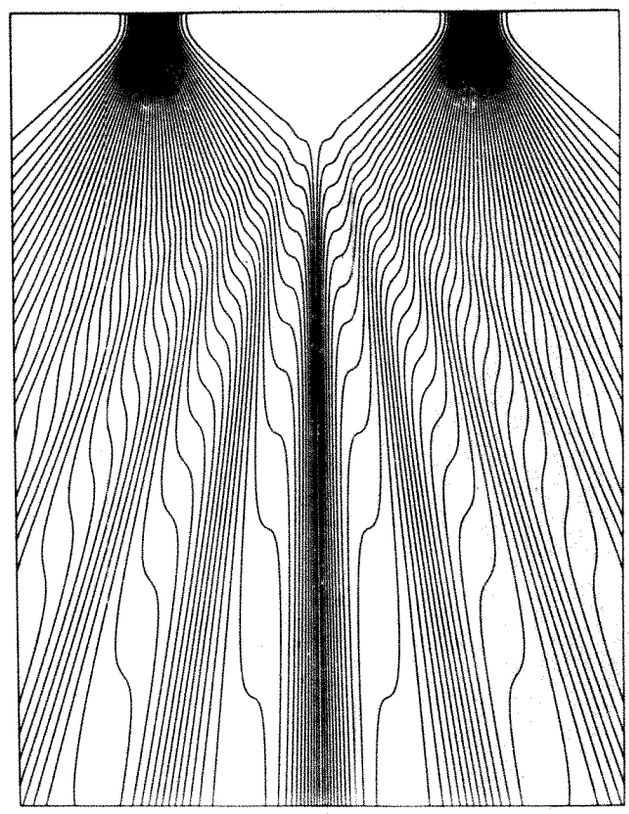

Fig. 3 Particle trajectories for particle passing through the two slits at the top and forming interference fringes at the bottom.

Each individual member of the ensemble goes one way or the other. That is, one of the wave-packets contains the particle and the other does not. As explained in our discussion of the measurement[2], if there is a particle detector for each packet, then the one actually containing the particle will be the one that registers. If, however, we allow interference to occur before we detect the particles, there will be a region of complex fluctuating quantum potential where the wave-packets overlap. When the particles enter this region, the trajectories will no longer be straight lines but rather will bunch into interference fringes in a way similar to what happens in the two-slit experiment. If the particles are detected, then the ensemble will show the interference pattern[15].

In no case is the behaviour of the system in the past modified. Each individual system will develop two wave-packets after passing through the half-reflecting mirror A (see Fig. 1). In each case the particle will go one way or the other, while the wave-packet is both transmitted and reflected. Indeed, which wave-packet the particle enters at A is determined by its (unknown) initial position in the incoming wave-packet (as can be shown by considering the scattering of a wave-packet from a square potential barrier[16]). No matter what is done later on in the experiment, for example, moving the pair of detectors from one position to another, this is not altered.

Until the two wave-packets travelling the two routes to F overlap, each particle follows a trajectory determined by a quantum potential independent of the existence of the alternative route. Detection at this stage by C_1' and C_2' simply gives information concerning which route the particle took. When the wave-packets overlap, the resulting quantum potential is determined by the physical conditions along both routes. In this region the trajectory of the particle is modified in such a way that the ensemble of trajectories produces an 'interference pattern' even though the particle has only travelled along one path. However, what we do with the detectors can affect the quantum potential that each particle experiences between the mirror and

the detector and in this way we obtain either a simple distribution of particles between alternative wave-packets or an interference pattern.

Conclusion

Here, we have shown that, using the quantum potential approach, it is possible to give a simple and intelligible account of a typical delayed-choice experiment. It is not necessary to suppose that the behaviour that we ascribe to a system in the past will depend in any way at all on what is done to it later. As we stated earlier, we feel this is more satisfactory than the approaches either of Heisenberg, who says that the orbit comes into being only when we observe it, or of Wheeler, who implies that the past has had no existence except in as far as it is recorded in the present.

Of course, to achieve this result we had to assume the particle trajectories that are not observable in detail, at least in any domain in which quantum mechanics is valid[11]. In this respect, our approach is similar to that of Heisenberg, who makes statements about the past that are also unverifiable by observation to give an account of how certain phenomena at different times may be related. However, by bringing in the quantum potential, we are able to understand the characteristic results of the quantum theory; for example, interference[14], barrier penetration[16], the Einstein-Podolsky-Rosen situation[17], the Schrödinger cat paradox and the measurement problem[2].

In this regard, our trajectories have essentially the same purpose as the trajectories of Heisenberg (although we think that our trajectories achieve much more). We do, however, find it difficult to understand why many authors reject the quantum potential approach on the grounds that it provides no new experimental consequences beyond those of the usual theory, while they are ready to engage in discussions of what may happen between measurements, discussions that equally have no further experimental consequences. Rather we agree with Wheeler who says "We search here not for new experiments or new predictions but for new insights". In this connection, we emphasize also that we are not proposing the quantum potential as a definitive explanation of the nature of reality. We do appreciate that the quantum potential is an arbitrary assumption, but think that the use of this assumption helps to understand the meaning of the quantum theory in an intuitively clear way. Many questions that are unclear in the usual interpretation (for example, the Einstein-Podolsky-Rosen experiment, the experiment discussed in this paper) became obvious in meaning when put in terms of the quantum potential.

Moreover, this interpretation gives results entirely compatible with Bohr's views on wholeness and complementarity. We regard our approach as complementing Bohr's instead of opposing it. To support this, we point out that our approach is generally more consistent with the spirit of the interpretations of Bohr and Wheeler than it is with the one adopted by Heisenberg. In other words, if one does want to use some sort of trajectory to explain the meaning of quantum mechanics, then the quantum potential is necessary if this is to be consistent and fully compatible with the experimental meaning of Bohr's interpretation.

Finally, as stated in the introduction, we agree with Wheeler that this is a participatory Universe. However, we suggest that this comes about because the observer-participator in, for example, determining the environmental context needed to observe a particle, creates a situation in which the fundamental mode of behaviour of the particle is strongly affected by this context (for example, the slit system can bring about a very irregular trajectory even when the particle is far away from it). Thus, the Universe cannot be analysed into elements that are essentially independent when they are far apart. In this way, the participation of the observer in the rest of the Universe (and of the rest of the Universe in the observer) has a far more profound significance than it has in classical physics. Through the quantum potential a certain insight into this significance has been made possible.

Role of lithospheric strength heterogeneities in the tectonics of Tibet and neighbouring regions

Philip England* & Gregory Houseman†

Unlike rigid oceanic plates, continents show diffuse deformation, for example the Tibetan plateau that has accommodated much of the convergence of India with Asia. We interpret the Tertiary deformation of Asia as the three-dimensional strain of a non-linear, viscous continental lithosphere. Lateral strength contrasts modify this deformation; stress concentration around the relatively strong Tarim basin gives rise to local crustal thickening in the Tien Shan to the north and to strike slip in the Altyn Tagh along its southern margin.

THE region accommodating the convergence between India and the Asian landmass is one of the clearest examples of non-plate-like behaviour of the continental lithosphere[1]. This deformation has been explained in several different ways. One interpretation involves the thrusting of India under the entire Tibetan plateau[2-4] but, although there is some present-day underthrusting of Indian crust underneath Tibet, recent seismic reflection[5,6] and palaeomagnetic[7,8] studies suggest that most of

Fig. 1 Locations of principal features referred to in this study. The 2,000- and 4,000-m contours are shown, with land above 4,000 m stippled; the position of the Altyn Tagh fault is taken from the map of Tapponnier and Molnar[9], to which reference should be made for positions for other major faults in the region.

the post-Eocene convergence between India and Asia has been taken up by shortening in Asia.

Continuum models for this intraplate deformation fall into two groups. The first emphasizes the role of strike-slip faulting in the present-day tectonics of Asia and interprets the deformation in terms of the predictions of plane-strain slip-line calculations[9], or by analogy with unscaled plane-strain plasticine models[10]. The second group represents the continental lithosphere by a thin non-linear viscous shell that can be analysed quantitatively as to its predictions about crustal thickness, strain and strain-rate fields and other parameters of finite deformation[11,12]. This approach recognizes the three-dimensional nature of the Tertiary deformation in Asia and accounts for the relatively greater importance of lateral motions at the present day in terms of the buoyancy forces generated by the elevation contrasts produced during the thickening of the Tibetan crust[9,12,13]. What these calculations have not contained so far is an analysis of the effect of a large-scale heterogeneity that is represented, for example, by the relatively aseismic and apparently undeforming Tarim basin[14] (Figs 1, 6). Here we pursue the implications of the thin sheet approach to continental tectonics[11-13,15,16] by assessing the influence of heterogeneities in lithospheric strength on the tectonics of Asia.

Mathematical model

The thin-sheet model has been described in detail elsewhere[12]; the lithosphere is represented by a thin layer of non-newtonian viscous fluid; for mathematical tractability we assume that horizontal gradients of crustal thickness and topography are small and use a depth-averaged constitutive relation of the form

$$\bar{\tau}_{ij} = 2\eta\dot{\varepsilon}_{ij} \tag{1}$$

where $\bar{\tau}_{ij}$ is the depth-averaged deviatoric stress component, $\dot{\varepsilon}_{ij}$ is the corresponding strain rate and η is the depth-averaged effective viscosity

$$\eta = \frac{B}{2}\dot{E}^{(1/n-1)} \tag{2}$$

where $\dot{E}$ is the second invariant of the strain-rate tensor and B is a depth-averaged strength coefficient. In the experiments described here, $n > 1$, so the effective viscosity is a function of position in the solution region.

The horizontal velocity components are assumed to be indepdent of depth in the layer and the solution is constrained by boundary conditions on the stress or velocity as shown in Fig. 2. The force balance equations for creeping flow are solved by finite element techniques.

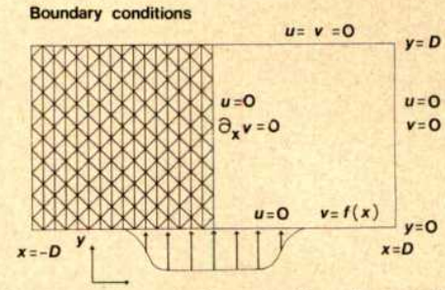

Fig. 2 Initial geometry, coordinates and boundary conditions for the numerical experiments. The x-y plane is horizontal, the line $x = 0$ is an axis of symmetry and the region is divided into triangluar elements as shown in the left. Velocities are zero on the boundary, except on the part of it that initially concides with the x-axis, where the region $-D/2 < x < D/2$ moves in the y-direction, representing the edge of an indenter. The motion of this boundary deforms the sheet (see Fig. 3). The velocity function that describes the indenter is: $v(x) = 0$ for $D/2 < |x| < D$, $v(x) = u_0$ for $0 < |x| < D/4$ and $v(x) = u_0 \cos^2(2\pi(x/D - 1/4))$ for $D/4 < |x| < D/2$. For convenience in the text, the positive y-direction is referred to as north, the positive x-direction as east, etc.

The rate of thickening or thinning of the crust is determined locally by the horizontal divergence of the calculated velocity field

$$\frac{1}{S}\frac{\partial S}{\partial t} = -\nabla \cdot \boldsymbol{u} \tag{3}$$

where S is the thickness of the crust and $\boldsymbol{u}$ is the velocity. Under the influence of gravity the thickened crust tends to spread horizontally, introducing a force proportional to the gradient of the square of crustal thickness into the dimensionless stress balance. The constant of proportionality is called the Argand number (Ar) by England and McKenzie[11] and is a measure of the magnitude of this gravitational spreading force relative to the viscous resisting forces.

The constant B(equation (2)) contains the depth averaged temperature dependence of the effective viscosity (see appendix of ref. 11) and hence is dependent on the geotherm, the depth to the Moho and lithological variations. Previous calculations[11-13] have assumed for simplicity that B is a constant. However, it has been suggested[14,16,17] that regions such as the Tarim basin are stronger and more resistant to deformation than the surrounding continental lithosphere. In the experiments described here, we investigate the consequences of including a small region of anomalously high strength in an otherwise

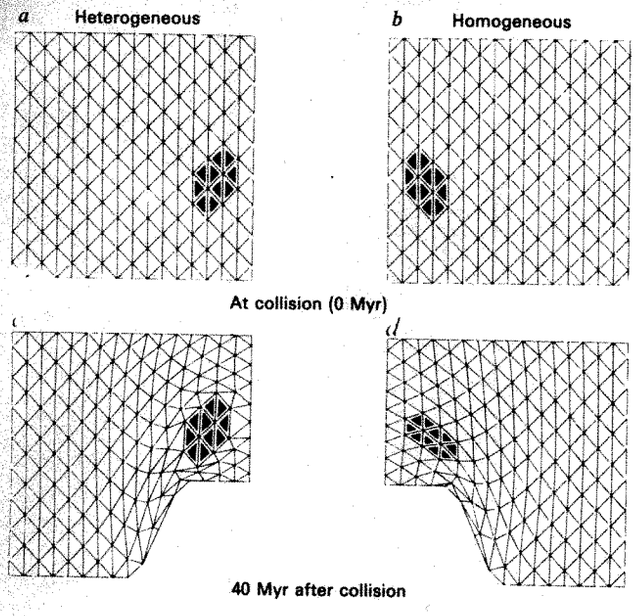

Fig. 3 *a*, *b*, Initial and *c*, *d*, final ($t = 40$ Myr) mesh configurations for the left and right halves, respectively, of the two symmetrical solutions for: *a* and *c*, the case where the effective viscosity coefficient (*B*, equation (2)) is increased by a factor of 10 in the shaded elements and *b* and *d*, the laterally homogeneous case, with the corresponding elements shaded for comparison with *a* and *c*. For both experiments $n = 3$ and $\mathrm{Ar} = 3$.

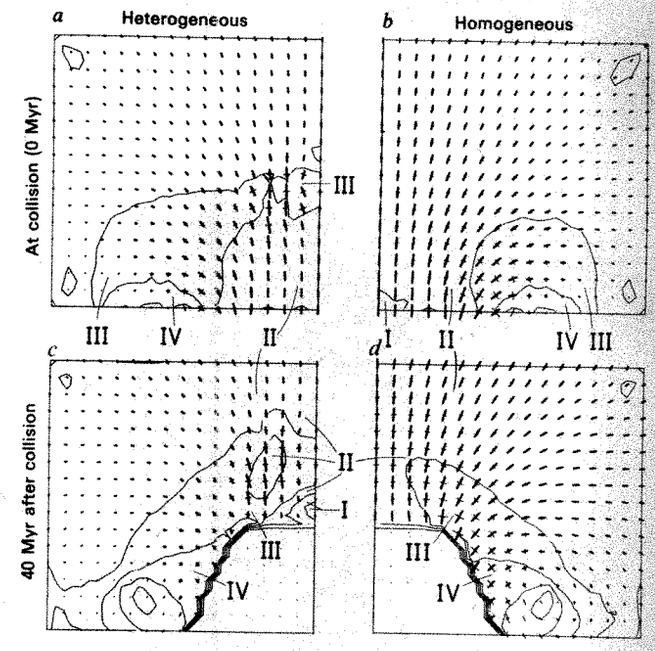

Fig. 4 Principal deviatoric stress axis orientation and magnitude for *a*, *b*, $t = 0$ and *c*, *d*, $t = 40$ Myr. The length of each arrow is proportional to the magnitude of the stress and the longest arrow represents a stress of *a*, 63.9 MPa, *b*, 43.5 MPa, *c*, 95.1 MPa and *d*, 44.2 MPa. Superimposed are contours of the parameter $\tan^{-1}(\dot{\varepsilon}_2/\dot{\varepsilon}_1)$, where $\dot{\varepsilon}_1$ and $\dot{\varepsilon}_2$ are principal horizontal strain rates. These contours divide the box into regions that show a consistent style of faulting (see text for II and III; I is a region of pure thrust faulting and IV is a region of normal plus strike-slip faulting).

laterally homogeneous layer; the constant B is increased by a factor of 10 in the shaded region of Fig. 3*a*. As a rough estimate of the effect of this modification, it follows from equations (1) and (2) that if the stress field is constant and the strain-rate field is uniaxial, then

$$\dot{E} \propto B^{-n} \tag{4}$$

For $n = 3$ the strain rates in the anomalously strong region would be only 10^{-3} of those in the surrounding regions. In fact, because of changes to the stress field (Fig. 4) and the triaxial nature of the strain-rate field, the contrast is in the range $0.5\text{–}1.0 \times 10^{-2}$.

Because of computation limitations, calculations were performed with an axis of symmetry along the perpendicular bisector of the indenter (Fig. 2). For the calculation shown in the left halves of Figs 3–6 there are two anomalously strong regions disposed symmetrically about the axis and having approximately the same positions relative to the indenter as do the Tarim and Qaidam basins to the arc of the Himalayan mountains (Fig. 1). We contrast these results with the calculation shown in the right halves of Figs 3–6 for the symmetrical laterally homogeneous case. By presenting in this format half of each solution, we mean to highlight the differences in tectonic style between western Tibet and Xinjiang province on the one hand and eastern Tibet and Gansu province on the other.

Results

We first describe the results of a calulation with $n = 3$ and $\mathrm{Ar} = 3$, as these parameters give reasonable agreement with observation, but also note that effective values of $n \leq 10$ and $\mathrm{Ar} \leq 10$ can give reasonable results (Fig. 6). Figure 3 shows the initial and final configuration ($t = 0$ and 40 Myr) of the finite element mesh for the two calculations. The vertices of each triangle are fixed to and carried along by the deforming medium. The strong region is barely deformed in Fig. 3*c* and has been translated and rotated practically as a rigid body; this behaviour should be compared with that of the corresponding region in the laterally homogeneous case (Fig. 3*b*, *d*).

The deviatoric stress fields in Fig. 4 show that the stresses in the strong region are amplified by the more rapid creep rates in the weaker material next to it (compare with ref. 18). At $t = 0$ the maximum stress in Fig. 4*a* is 47% greater than that of the corresponding laterally homogeneous case (Fig. 4*b*) and is found in the strong region rather than on the corner of the indenter. After 40 Myr (Fig. 4*c*), the maximum stress in the basin has increased by a further 49%. There is also a slight rotation of the principal stress axes near the viscosity heterogeneity.

Superimposed on the stresses of Fig. 4 are contours separating regions with a different style of surface faulting, assuming that the upper brittle crust deforms with the same strain rates as the underlying ductile layer. In region II, both strike-slip and thrust faulting must occur, although there is a greater rate of moment release from the thrust faulting component. In region III, the same two fault styles would be observed, but the rate of moment release from the strike-slip component is greater in this region.

For both calculations (with the strong region, Fig. 4*a*, *c*, and the homogeneous case, Fig. 4*b*, *d*) region III increases in lateral extent as the indenter moves further north, because as the crust is thickened the gravitational forces tend to resist further crustal thickening (thrust faulting) and an increasing percentage of the deformation is accommodated by strike-slip faulting[11,13]. When the strong region is present, strike-slip deformation is predominant on its east and west margins throughout the deformation (Fig. 4*a*, *c*). At the centroid of the element next to the southern corner of the strength heterogeneity, the rate of moment release for thrust faulting is 3.7 times that for strike-slip faulting at $t = 0$, but at $t = 40$ Myr the strike-slip component is greater than that of the thrusting by 46%. For the same material point in the homogeneous calculation, thrust faulting is dominant throughout, although the ratio of thrust moment to strike-slip moment falls from 3.6 to 1.2 during the 40 Myr. The region next to the south-east margin of the basin, which at 40 Myr shows the maximum strain rates and strongest crustal thickness gradients (Fig. 6*a*), is thus found to be undergoing predominantly strike-slip deformation (Fig. 4*c*) during the last 10 Myr of the calculation. This region is in the same position relative to the basin as is the Altyn Tagh fault system relative to the Tarim basin (Fig. 1).

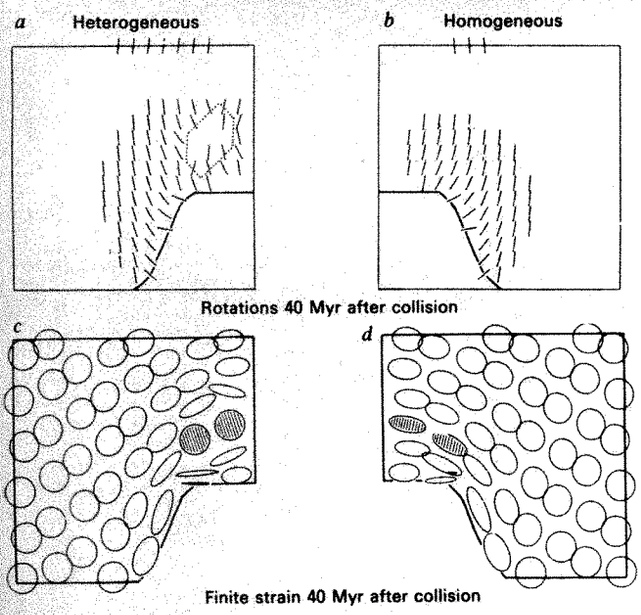

Fig. 5 *a*, *b*, Finite rotations (half of the time-integrated vorticity) at $t = 40$ Myr; *c*, *d*, finite deformation ellipses at $t = 40$ Myr; for *a*, *c*, the case with the strong region and *b*, *d*, the laterally homogeneous case. For *a* and *b* the angle between the small bar and the *y*-axis is the magnitude of the rotation; only rotations $>5°$ are shown. For *c* and *d* the ellipses show the finite strain, after 40 Myr, of initially circular horizontal material elements. The shaded ellipses in *c* lie in the basin and the corresponding ellipses are shaded in *d*.

Figure 5 shows the finite rotation and deformation in the two cases. Only rotations $>5°$ are shown so the strong region in Fig. 5*a* is defined clearly by the small magnitude ($\sim 5°$) and opposite sign of its rigid-body rotation, compared with the anticlockwise rotation of 30–40° of the material to its north-west and south-east. The rotations on the northwestern margin of the basin are significantly greater than they would be in the absence of the viscosity heterogeneity (Fig. 5*b*) and significant clockwise rotations ($\sim 20°$) are also found on its north-east and south-west margins; otherwise the distribution and magnitude of rotation is much the same as in the homogeneous case.

Figure 5*c*, *d* is an alternative presentation of the data shown in Fig. 3*c*, *d*. Each ellipse shows the finite deformation undergone by a particular triangular element. The strain ellipses from the strong region (shaded) show ratios of major to minor semiaxes of 1.010 and 1.007 respectively, compared with the ratios for the corresponding ellipses in the homogeneous case of 2.39 and 2.35.

Figure 6*a*, *b* illustrates the elevations calculated for this model at 40 Myr after collision, compared with those observed in Asia at the present day. Because of the assumption of Airy isostasy in these calculations, contrasts in elevation are proportional to contrasts in crustal thickness. The contours of Fig. 6*a*, *b* show the most obvious effect of the viscosity anomaly; crustal thickening is inhibited within the strong region, whereas it is enhanced both to the north and south of the anomaly. Assuming isostatic balance, the topography would show a basin in the area corresponding to the anomalously strong region; after 40 Myr (Fig. 6*a*) the deepest part of the basin still has a 35-km-thick crust. To the south of the basin there is a steep topographical gradient where the crustal thickness increases by >20 km as the indenter is approached and near the corner of the indenter the crustal thickness is more than doubled to 75 km. Immediately north of the indenter on the axis the crustal thickness is ~64 km, some 6 km thicker than for the laterally homogeneous calculation (Fig. 6*b*). To the north of the basin there is another local maximum of 55–60-km-thick crust. This local maximum bears the same geographical relation to the basin as does the Tien Shan mountain range to the Tarim basin (Fig. 1). In comparison,

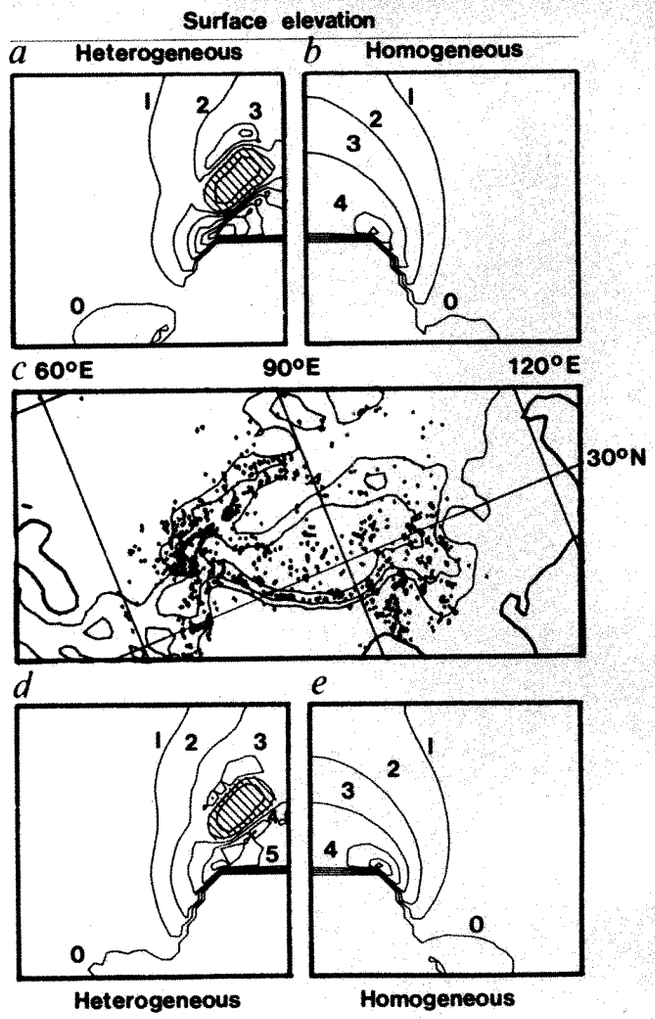

Fig. 6 Contours of elevation 40 Myr after collision for *a*, *d*, heterogeneous and *b*, *e*, homogeneous thin sheets, compared with *c*, contours of elevation in Asia. We assume an initial crustal thickness of 35 km, and changes in elevation $(e - e_0)$ are related to changes in crustal thickness $(S - S_0)$ by $(e - e_0) = (S - S_0)(1 - \rho_c/\rho_m)$. For $\rho_c = 2{,}800\ \mathrm{kg\ m^{-3}}$ and $\rho_m = 3{,}330\ \mathrm{kg\ m^{-3}}$ (ref. 22) difference in elevation of 1 km is equivalent to a difference in crustal thickness of 6.3 km in the model. In *a* and *b*, $n = 3$ and $\mathrm{Ar} = 3$; the shaded region in *a* has a contrast in *B* of a factor of 10 relative to its surroundings. In *d* and *e*, $n = 10$ and $\mathrm{Ar} = 10$ and the shaded region in *d* has *B* greater by a factor of 2 than its surroundings. Contours of topography in *c* are taken from Lee's[23] $1° \times 1°$ averages, smoothed with a gaussian filter of width 2°; contouring intervals are 1 km. Dots indicate earthquakes in the interval 1964–1980, shallower than 100 km and reported to the International Seismological Centre by more than 25 stations. Note the relative quiescence in the seismicity of the Tarim basin.

the laterally homogeneous case (Fig. 6*b*) shows a monotonic decrease in crustal thickness northwards of the indenter.

A second important result of these calculations is illustrated in Fig. 6*d*, *e*, which shows the results of a calculation similar to that illustrated in Fig. 6*a*, *b* except that $n = 10$, $\mathrm{Ar} = 10$ and the contrast in *B* for the strong region in the heterogeneous calculation is 2 (giving approximately the same contrast for uniaxial strain rates (equation (4)) as does a contrast of 10 when $n = 3$). With the minor difference that the peak crustal thickness near the corner of the indenter is decreased, the distribution of the topography in Fig. 6*c* resembles closely that of the topography in Fig. 6*a*. The resemblance emphasizes that the role of

heterogeneous inclusions in determining the scale lengths of continental deformation may be as important as that of the deformation mechanisms.

It would be difficult to distinguish, on the basis of the calculations shown in Fig. 6, between a model with a power-law exponent of 3, appropriate to a lithosphere governed by the deformation of olivine, and one with an effective power law exponent of 10, perhaps reflecting a significant contribution to the vertically averaged rheology from friction on faults.

Discussion and conclusions

The magnitude of the strength contrast required to produce the features described here is surprisingly small; for $n=3$ a factor of 10 is more than adequate, and for larger values of n a smaller strength contrast would be sufficient. Assuming that the strongest part of the lithosphere is the uppermost mantle, we may use the power-law rheology given for olivine by Goetze[19], and the expression of England[20] for the vertically averaged strength of a lithosphere governed by such a rheology, to estimate the drop in temperature at the Moho that is implied by increasing B (equation(2)) by a factor of 10. For $n=3$ and Moho temperatures in the range 600–800 °C, the implied temperature decrease is ~100 °C, which is consistent with the suggestion of Molnar and Tapponnier[14] that strength contrasts in the Asian lithosphere may be related to differences in geothermal regime in the region. However, we must caution against too literal interpretation of these calculations in terms of a specific rheological model, in view of the many uncertainties involved in applying the results of laboratory measurements to the deformation of the continental lithosphere.

We have shown that the strain-rate fields and distribution of deformation in a thin viscous layer acted on by a rigid indenter are modified strongly by the presence of a strength heterogeneity in the layer. The most important features predicted by the calculations here are the preservation of a relatively low-lying region that is surrounded by thicker crust and higher topography, relatively small strain rates and total strain within this basin and a narrow zone of steep crustal thickness gradients and predominantly strike-slip deformation separating the basin from the plateau of much thicker crust to its south. It seems probable that if the symmetry requirement were dropped and the calculation were performed with a single heterogeneity corresponding to the Tarim basin, there would be a net eastward mass flux across the line that bisects the indenter and enhanced strike-slip motion at the southern edge of the high strength inclusion. The above features are all consistent with the interpretation of the Tarim basin as a relatively strong lithospheric block emplaced in an otherwise laterally homogeneous thin viscous layer; in this context the model explains the formation of the Tien Shan range and the Altyn Tagh strike-slip fault system. It seems likely that lithospheric strength heterogeneities (for example, the stable region of central Iran[21]) have similar roles in other collision orogenies.

Abrogation of metastatic properties of tumour cells by *de novo* expression of H–2K antigens following *H–2* gene transfection

H-2 gene transfection was used to restore expression of H-2K antigens in metastatic and non-metastatic subclones of a murine fibrosarcoma that lack their major histocompatibility complex-encoded H-2K antigens. De novo *expression of H-2K reduced tumorigenicity and abolished the formation of metastasis in syngeneic mice. Expression of H-2K may lead to effective recognition of the disseminating tumour cells by the host immune system.*

THE major histocompatibility complex (MHC) of the mouse (*H-2*) encodes a group of cell-surface antigens that are involved in various pathways of the immune response. Thus, cytotoxic T lymphocytes (CTL) can recognize cells infected with virus or altered by neoplastic transformation only in association with an H-2 antigen (reviewed in ref. 1). It depends on the antigen as to which of the three known H-2 class I antigens, K, D or L, serves as a restriction element for CTL[1]. Hence, it is conceivable that the control of tumour growth by the immune system would depend not only on the existence of tumour-associated cell-surface antigens, but also on the expression of MHC-encoded antigens on the tumour cells. Therefore, modulation of H-2 antigens of tumour cells may alter their growth properties because of alterations in the immune response of the host to the neoplastic cells.

Recent studies have demonstrated that the metastatic properties of certain mouse tumours are correlated with the relative expression of class I MHC antigens[2–9]. A notable example is the methylcholanthrene-induced T10 sarcoma of ($H\text{-}2^b \times H\text{-}2^k$) F_1 origin. Two distinct sets of T10 clones were isolated, differing not only in their metastatic potential but also in their expression of class I MHC antigens[4,5]. According to their genotype, the tumour cells should express four different H-2 molecules, namely K^b, D^b, K^k and D^k. However, both sets of clones were

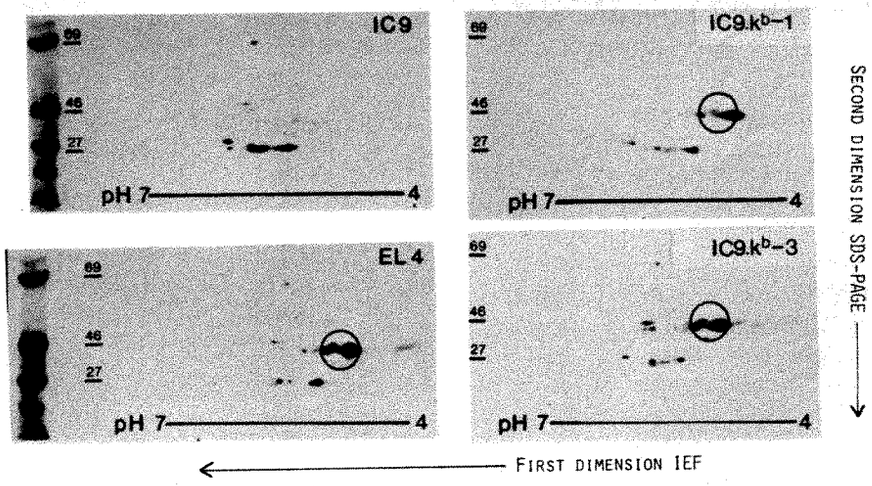

Fig. 1 Two-dimensional isoelectric focusing (IEF) gel of H-2K region associated antigens. $1-3\times10^6$ tumour cells (IC9, K^b-transfected IC9 and C57BL/6-derived EL4 lymphoma) were pulse labelled for 6 min at 37 °C in the presence of 200 μCi ^{35}S-methionine and lysed in ice-cold Tris buffer containing 1% Triton X-100. Cell lysates were preabsorbed with Protein A-Sepharose 4B for 2 h. H-2 proteins were immunoprecipitated using a mixture of monoclonal anti-H-2K^b antibodies K10-56, K9-136, K7-309, K9-178 (ref. 13) (20× concentrated culture supernatant) followed by Protein A-Sepharose for 5 h. Two-dimensional IEF gels were performed according to O'Farrell[30]. Second-dimension gels were 10% acrylamide. Gels were processed with 2,5-diphenyloxazole dried, and exposed for 2 weeks using Kodak XAR-5 film. β_2-Microglobulin, relative molecular mass 12,000, runs through the second-dimension gel and is therefore not visible on autoradiograms. Circles indicate positions of H-2K^b proteins. EL4 yields the same K^b spots as spleen cells from the C57BL/6 mice used for breeding of the C3H×C57BL/6 mice used in this study (not shown).

found to lack the K end-controlled K^b and K^k antigens. The non-metastatic clones express only the D^b molecule whereas the metastatic clones express both the D^b and D^K molecules (refs 6, 7; see also Table 1). Further studies suggested that the D^k molecule contributes to the metastatic potential of these clones[8].

Here, we seek to determine whether expression of H-2 molecules encoded by the K end of the H-2 complex would influence metastatic spread and tumorigenicity of the T10 fibrosarcoma clones. To elucidate this problem we transfected clones of the T10 sarcoma with cloned *H-2K* genes and tested the malignant properties of the transfected tumour cells in syngeneic mice.

Restoration of H-2 expression

For transfection with *H-2* genes a representative non-metastatic tumour clone (designated IC9) and a metastatic clone (IE7) were selected from the two sets of T10 fibrosarcoma clones. Cells were co-transfected with *H-2K^b* (ref. 10) or *H-2K^k* plasmid DNA[11] and plasmid pAG60 containing the neomycin resistant gene (*neo^r*) (ref. 12) and subsequently selected in medium containing Geneticin, which selects for cells that have productively integrated the *neo^r* gene. We identified colonies expressing transfected *H-2* genes using specific monoclonal H-2 antibodies at a frequency of ~10-30%. After cloning of positive colonies,

Table 1 H-2 phenotype of transfected IE7 and IC9 tumour clones

Cell line	Transfected genes	H-2 antibody (c.p.m. obtained) Anti-D^b	Anti-K^b	Anti-D^k	Anti-K^k	H-2 phenotype

Transfection was performed according to Wigler *et al.*[26] with some modifications. pBR322 plasmids containing the 10.5-kilobase (kb) *Eco*RI fragment of the *H-2K^b* and *H-2K^k* genes, respectively, were generously provided by Drs R. Flavell[10] and B. Arnold[11]. The *H-2K^k* gene (cos10.7) originally came from Dr M. Steinmetz. The plasmid pAG60 (ref. 12) containing *neo^r* was obtained from Dr B. Dobberstein. IC9 and IE7 cells were seeded at a density of ~10^6 cells per 10-cm Petri dish. Various mixtures of *H-2* DNA (4 μg), *neo^r* (0.4 μg) and salmon-sperm DNA (20 μg), precipitated with calcium phosphate, were added. After 5 h at 37 °C the medium was replaced by 5 ml 15% glycerol or a 41% solution of polyethylene glycol 4000 for 2 min. After overnight incubation with medium, the cells were collected with EDTA buffer and distributed into two COSTAR 3524 multiwell plates in selection medium containing 0.7 mg ml^{-1} Geniticin (G418, Gibco). Growing colonies (1-10 per 10^6 input cells) were expanded, tested for H-2 expression by cytofluorography or radioimmunoassay and cloned by limiting dilution. (Without glycerol or polyethylene glycol almost no transfectants were obtained.) The table shows a representative cellular radioimmunoassay which was performed as described previously[27]. Briefly, 10^6 cells were incubated in microtitre plates with specific anti-H-2 monoclonal antibody (anti-D^b, hybridoma B22-249, ref. 28; anti-K^b, K10-56, ref. 13; anti-D^k, 15-5-5S and anti-K^k, 16-3-22, ref. 13). After washing, ^{125}I-labelled Protein A was added and the amount of bound radioactivity determined. Values represent the mean of triplicate wells. The standard deviation ranged between 5 and 10% (not shown). Background with irrelevant antibodies was always <1,000 c.p.m. (not shown). The c.p.m. obtained with different H-2 antibodies cannot be compared because the affinity and amount of specific antibody in the hybridoma supernatant are probably different.

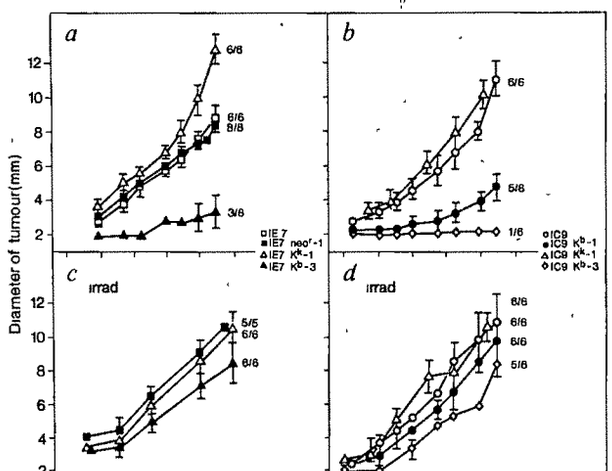

Fig. 2 Growth of parental and *H-2K*-transfected IE7 and IC9 cells. 10^4 *neo*^{r} and *H-2K*-transfected IE7 (*a*, *b*) or IC9 (*c*, *d*) were injected i.f.p. into intact (C3H.eB×C57BL/6)F_1 mice (*a*, *c*) and into sublethally irradiated (550 rad) F_1 mice (*b*, *d*). Tumour size was recorded using a caliper. The growth curves represent the mean tumour size of all mice inoculated in each experimental group ±s.e.m., including the diameter of legs of mice which rejected the inoculated cells. Mean diameter of legs of control non-inoculated mice is 2 mm. The numbers designated above each growth curve represent the proportion of mice that developed a tumour of the entire experimental group. *a*, *b*, □, IE7; ■ IE7.neo^r-1; △, IE7.K^k-1; ▲, IE7.K^b-3. *c*, *d*, ○, IC9; ●, IC9.K^b-1; △ IC9.K^k; ◇ IC9.K^b-3.

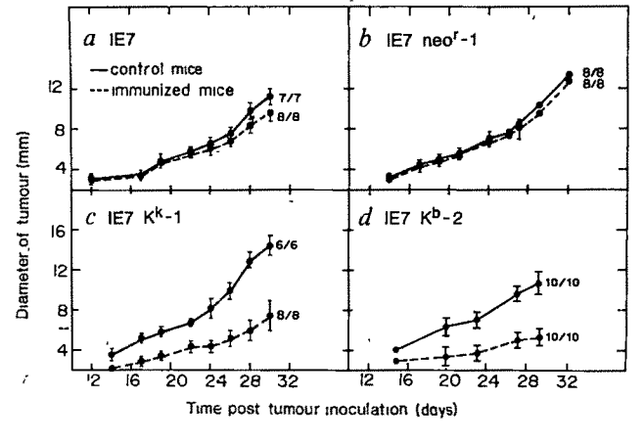

Fig. 3 *In vivo* immunogenic properties of IE7, parental and *H-2K*-transfected cells. (C3H.eB×C57BL/6J)F_1 female mice, aged 2 months, were inoculated with: *a*, 1×10^6 IE7 parental tumour cells; *b*, with IE7 cells transfected with *neo*^{r} gene only; *c*, with *H-2K*^{k}-transfected IE7 cells; *d*, with *H-2K*^{b}-transfected IE7 cells. One week later, the tumour-inoculated leg was amputated as described in Table 2 legend (immunized mice). Mice were then re-inoculated i.f.p. with 10^4 tumour cells of the immunizing origin. (Control mice were amputated as well.) Tumour growth in the immunized and control mice were measured using a caliper. Growth curves represent the mean tumour diameter of all mice inoculated ±s.e.m., including the diameter of legs of mice that did not develop tumours. Mean diameter of legs of control mice is 2 mm. The numbers designated above each growth curve represent the proportion of mice that developed a tumour.

the H-2 phenotype was determined in four different assays: (1) cytofluorography; (2) cellular radioimmunoassay; (3) lysis by alloreactive H-2-specific CTL; and (4) immunoprecipitation with monoclonal H-2 antibodies. All tests yielded identical results, but for the sake of brevity only a typical cellular radioimmunoassay using monoclonal H-2 antibodies and ^{125}I-labelled Protein A and a representative selection of transfected cell lines is presented.

Parental IC9 cells or IC9 transfected with *neo*^{r} alone express only the D^b molecule, whereas IC9 cells transfected with *H-2* genes also synthesize the K^b- or K^k antigens (Table 1). Correspondingly, parental IE7 cells or IE7 transfected with *neo*^{r} alone carry only D^b and D^k, whereas *H-2*-transfected IE7 also express K^b or K^k antigens. K^b- or K^k-positive cells were obtained only after transfection with the appropriate *H-2K* genes and never after subcloning of parental tumour cells or after transfection with *neo*^{r} alone (>500 colonies tested).

Because the intention of the work was to study the influence of *H-2* expression on interaction of the tumour cells with a syngeneic host, it was important to establish that the transfected *K*^{b} and *K*^{k} molecules are not modified in some way, for example by intragenic recombination of the transfected *H-2* gene with the host genome. Neither serological analysis with >20 monoclonal antibodies against distinct epitopes[13] on the H-2 molecules (data not shown) nor two-dimensional gel electrophoresis revealed any abnormalities (Fig. 1). The K^b spots immunoprecipitated from *K*^{b}-transfected IC9 cells (marked with a circle) are identical to those obtained from a K^b-positive cell line of C57BL/6 origin, EL4. In addition, Northern blot analysis of H-2K end-specific messenger RNA, which is found in IC9 and IE7 cells only after transfection with *H-2K* genes, did not show any unusual H-2-specific mRNA (E. Meyer and G.J.H., unpublished). It is not yet clear why the parental IC9 and IE7 cells fail to express their H-2K antigens. That the respective *H-2K* genes are present in these tumours is shown by genomic Southern blot analysis with an H-2K-specific probe (E. Meyer and G.J.H., unpublished).

Two points can be made from these findings. First, transfection with cloned *H-2* genes can be used to restore H-2 expression in cells that have lost expression of their H-2 antigens. Second, there is no evidence for an alteration of the H-2 molecules encoded by the transfected genes.

Metastatic properties

Tumorigenicity and metastatic potential of the H-2K-transfected tumour cells was investigated by inoculation of 10^4–10^6 tumour cells into the hind foot pad of syngeneic (C3H×C57BL/6)F_1 mice. Expression of either K^b or K^k antigens on the surface of IE7 cells resulted in loss of their metastatic potential (Table 2). IE7 cells transfected with the *neo*^{r} gene alone retained the metastatic properties (for example, cell line IE7.neo^r-1). Consistent results were obtained with nine additional IE7 clones transfected with *neo*^{r} alone and with five additional IE7 lines derived from transfection with *K*^{b} or *K*^{k} genes (data not shown). In contrast to lack of metastasis in normal mice, the H-2K-transfected IE7 lines were found to metastasize in irradiated (C3H×C57BL/6)F_1 mice (Table 2). For irradiation, 550 rad were used, a dose that strongly reduces host immune reactivity. The findings suggest that the immune system of the host controls the ability of transfected cells to metastasize. Transfection of the non-metastatic IC9 cells with *H-2K* genes did not change their inability to metastasize in normal mice (Table 2). However, like transfected IE7, these cells were able to metastasize in irradiated mice.

Simultaneously, we tested whether the tumorigenic properties of the H-2K-transfected cells were also affected. We inoculated (into the foot pad) 10^4 transfected IE7 cells into syngeneic (C3H×C57BL/6) F_1 mice and recorded tumour growth (Fig. 2). K^b-positive IE7 cells (IE7.K^b-3) were found to grow significantly slower than the control IE7 cells (Fig. 2*a*). In fact, only three out of six mice developed a tumour. The transfected IE7 cells growing *in vivo* were still K^b-positive when analysed for H-2 expression (not shown) and, therefore, the tumour growth cannot be attributed to loss of K^b. In contrast, IE7 cells transfected with *K*^{k}, (IE7.K^k-1) or with *neo*^{r} alone (IE7.neo^r) grew like parental IE7 in all mice inoculated (Fig. 2*a*). Similar growth patterns were obtained with four other *K*^{b}, two *K*^{k} and nine *neo*^{r}-transfected IE7 cell lines and when different doses of transfected IE7 cells were injected (10^5, 10^6 cells per mouse; data not shown). Thus, expression of K^b antigens on IE7 cells

decreased their tumorigenic properties. In irradiated mice, K^b-transfected IE7 grew like parental cells (Fig. 2*b*), suggesting that the immune system of the host also controls growth of the local tumour. The fact that IE7 cells transfected with K^k or K^b genes are both non-metastatic but manifest different growth rates suggests that expression of H-2K antigens on the tumour cells blocks metastasis irrespective of the growth kinetics of the tumour.

The tumorigenic properties of the non-metastatic IC9 clone were also affected by transfection with *H-2K* genes. K^b-positive IC9 cells were found to grow more slowly in syngeneic F_1 mice than in parental IC9 or IC9 transfected with *neo*^{r} alone (Fig. 2*c*). In fact, cells of the transfected IC9.K^b-3 line were rejected in five out of six mice (Fig. 2*c*). For other K^b-transfected IC9 lines, the percentage of rejection was in general lower and varied between 5 and 20%. The higher rate of rejection of IC9.K^b-3 compared with other K^b-transfected IC9 lines seems to correlate with the amount of K^b expressed on these cells (see Table 1). The K^b-transfected IC9 growing in mice still expressed H-2K^b (not shown). Similar growth curves were recorded when 10^5 and 10^6 cells of IC9 transfected cells were inoculated, but the percentage of mice without a tumour was lower than with 10^4 injected cells (data not shown). All transfected IC9 lines were able to grow like parental IC9 in irradiated mice (Fig. 2*d*). The results presented so far indicate that transfection of IC9 and IE7 cloned cells with *H-2K* genes leads to the abolition of metastatic competence and a decrease in tumorigenicity. Our experiments with irradiated mice suggest that the immune system is involved in reduction of metastasis and tumorigenicity.

Immunogenic properties

We next tested whether the reduction in metastasis in *H-2K*-transfected IE7 cells is associated with increased immunogenicity. F_1 mice were immunized with transfected tumour cells and then challenged with homologous tumour cells (Figs 3, 4). IE7 parental cells (Fig. 3*a*) and IE7 cells transfected with *neo*^{r} gene only (Fig. 3*b*) showed the same growth rate in immunized and control mice and, therefore, do not seem to be immunogenic. In contrast, immunization with IE7.K^k-1 (Fig. 3*c*) or with IE7.K^b-1 cells (Fig. 3*d*) led to retarded growth of the corresponding tumour cells. In agreement with previous observations[10], the non-metastatic parental IC9 cells proved to be slightly immunogenic (Fig. 4*a*). However, expression of K^b on transfected IC9 cells led to a drastic increase in immunogenicity, resulting in complete rejection in respectively immunized mice (Fig. 4*b–d*).

Table 2 Metastatic potential of H-2K-transfected IE7 and IC9 cells in normal and irradiated syngeneic (C3H×C57BL/6)F_1 mice

A single-cell suspension of 10^5 *neo*^{r}- and *H-2K*-transfected IE7 and IC9 cells were inoculated intra footpad (i.f.p.) into intact and sublethally irradiated (550 rad Co) (C3H×C57BL/6)F_1 mice. When the tumour diameter reached a size of 8–10 mm, the tumour-bearing leg was amputated using a 3/0 silk tie, which was ligated beyond the iliofemoral joint of the hind leg to prevent bleeding. In each experimental group, mice were killed 21 days post-amputation, and their lungs removed and assessed for metastatic load by weight and by number of nodules counted after fixation in Bouin's solution. Without excision of the primary tumour the number of metastatic nodules is much lower[29]. Corresponding results were obtained with both protocols, but only data generated with the excision protocol are presented. Other independent experiments yielded identical results (not shown).

* H-2 phenotype according to results presented in Table 1.

Table 3 Generation of CTL specific for transfected tumours in (C3H×C57BL/6)F_1 mice

Immunization	Target cells (% specific lysis) IC9	IE7	(IC9.K^b-3)	(IE7.K^b-1)	(IC9.K^k-1)	(IE7.K^k-1)	EL4	L929
IC9	0	0	0	0	0	0	0	0
IE7	0	0	0	0	0	0	0	0
(IC9.K^b-3)	0	0	45	28	0	0	0	0
(IE7.K^b-1)	0	0	40	35	0	0	0	0
(IE7.K^k-1)	0	0	0	ND	ND	59	0	5

(C3H×C57BL/6)F_1 mice were immunized three times at weekly intervals with 10^6 tumour cells irradiated with 3,000 rad. After 7–10 days, spleen cells were restimulated *in vitro* with the same tumour cells irradiated with 10,000 rad. Cytolytic activity was determined at different effector-to-target ratios against ^{51}Cr-labelled target cells including EL4 (H-2^b) and L929 (H-2^k) as controls Data show per cent specific lysis obtained with an effector/target ratio of 50:1. ND, not determined.

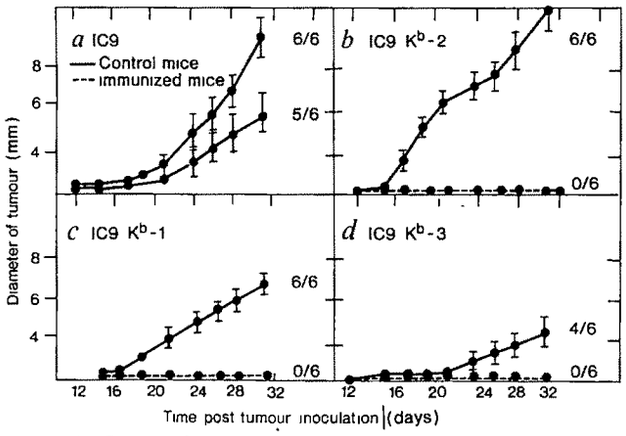

Fig. 4 *In vivo* immunogenic properties of IC9 parental and $H\text{-}2K^b$-transfected cells. Syngeneic F_1 mice were immunized against. *a*, IC9 parental cells and, *b–d*, against $H\text{-}2K^b$-transfected IC9 cells. Immunization and the immunogenic properties of the different tumour cells were followed as described in Fig. 2 legend.

In conclusion, expression of H-2K antigens on IC9 and IE7 cells confers highly immunogenic properties on these cells.

Generation of cytotoxic T lymphocytes

Spleen cells from syngeneic $(C3H \times C57BL/6)F_1$ mice immunized with irradiated tumour cells were restimulated *in vitro* and their cytotoxic activity was determined against a panel of target cells (Table 3). Immunization with parental IC9 or IE7 cells did not lead to generation of CTL. In contrast, specific Thy-1.2$^+$ CTL were obtained, after immunization with K^b-transfected IC9 or IE7 cells. These CTL lysed only K^b-transfected IC9 and IE7 but not parental IC9 or IE7 cells, or EL4, an unrelated K^b-positive tumour. The findings suggest that the CTL can recognize an unknown tumour-associated antigen on IC9 or IE7 only in conjunction with K^b. Likewise, K^k-restricted CTL were found after immunization with K^k-transfected IE7. The fact that CTL induced with K^b-transfected IC9 can also lyse K^b-transfected IE7, and vice versa, indicates that both IC9 and IE7 carry the same tumour-associated antigen.

Discussion

The data presented here suggest that manipulation by gene transfection of H-2K expression on $(H\text{-}2^b \times H\text{-}2^k)F_1$ mouse-derived T10 sarcoma cells leads to changes in the malignant properties of these cells. Thus, the H-2K-negative and highly metastatic IE7 cells lost their capacity to metastasize when made to re-express H-2K antigens by *H-2K* gene transfection. Moreover, K^b-transfected IE7 or IC9 cells manifested a decrease in their tumorigenic properties. The crucial question is whether the modulation of tumour growth does indeed result from the *de novo* expression of H-2K antigens. The most convincing argument is that all IE7 clones expressing only the *neo*^{r} gene still metastasize and grow *in vivo* like the parental IE7 cells. Similarly, all IC9 clones transfected with *neo*^{r} alone grow like the non-metastatic parental IC9.

IE7 cells transfected with either *H-2K* or parental and transfected IC9 metastasized when inoculated into sublethally irradiated mice, suggesting that in the case of these tumour cells the immune system is involved in preventing metastasis formation. Indeed, the efficient immunization with H-2K-positive IE7 and IC9 cells (Figs 3, 4) and the induction of CTL by *H-2K*-transfected cells (Table 3) demonstrates that the *de novo* expression of H-2K converts the tumours into highly immunogenic cells. The resulting CTL lysed only H-2K-positive, but not parental, cells. These findings indicate not only that the presence of H-2K antigens on the tumour cells is required for induction of immunity, but also that H-2K is part of the target structure recognized by effector cells.

The results presented here are consistent with many reports showing that CTL raised against foreign cellular antigens can be preferentially restricted by the H-2K or the H-2D molecules depending on the antigen and *H-2* haplotype involved[1]. Thus, it is conceivable that in the case of the IC9/IE7 tumour system, the D^b and D^k molecules fail to act as H-2 restriction elements for T-cell recognition. In contrast, the putative tumour associated antigen on IE7 cells, the nature of which is unknown, can be efficiently recognized in conjunction with the transfected K^b or K^k, resulting in the elimination of disseminating metastatic cells. As only expression of K^b but not K^k leads to retarded growth of the primary tumour, it seems that K^b renders the cells more immunogenic than K^k. However, the resulting K^k-restricted immune response seems to be strong enough for elimination of metastasizing K^k-transfected IE7 cells, possibly because the disseminating cells are more accessible than the locally growing tumour. In addition to the potential failure of H-2D molecules to function as H-2 restriction elements, accumulating data suggest that H-2D antigens may play an active role in the prevention of immune responses[14–17]. In fact, recent experiments suggest that the D^k molecule on IE7 cells exerts suppressogenic effects on the host response[9]. Other non-immunological effects of H-2 antigens cannot be excluded at this point.

The frequently observed absence of class I MHC antigens on tumours[2,3,18,19] may have important implications for the immune surveillance of neoplastic cells. This notion has been substantiated here and by other recent reports[20–22]. While this manuscript was in preparation, Hui *et al.*[23] reported that restoration of H-2K^k expression by gene transfection led to reduced tumorigenicity of a non-metastatic AKR thymoma, which is in agreement with our observations on the solid T10 sarcoma. The functional importance of class I MHC antigens in the animal systems described above may also have implications for the phenotypic expression of malignancy of human neoplasms. Indeed, there is some recent evidence that the malignancy of certain human tumours seems to be correlated with expression of HLA class I antigens[24,25].

RS Ophiuchi — first radio detection of a recurrent nova outburst

S. Padin*, R. J. Davis* & M. F. Bode†

* University of Manchester, Nuffield Radio Astronomy Laboratories, Jodrell Bank, Macclesfield, Cheshire SK11 9DL, UK
† Department of Astronomy, University of Manchester, Manchester M13 9PL, UK

Recurrent novae and classical novae belong to the cataclysmic variable class of objects. Of these, only classical novae outbursts have been hitherto observed at radio wavelengths, and then no earlier than 50 days after the outburst. Here we report the first radio detection of an outburst from a recurrent nova (RS Ophiuchi). The observations begin only 18 days after the optical maximum and show a radio 'light' curve which is different from that of classical novae. The brightness temperature of $\sim 10^7$ K, calculated for this event, greatly exceeds the 10^4 K seen in classical novae, and suggests a non-thermal origin for the radio emission from RS Ophiuchi. Although the later emission has a classical $(t-t_0)$ 'light' curve, the radio emission mechanism appears not to turn on until 14 days after the optical nova and takes a further 10 days to reach the $(t-t_0)$ curve. Analogies may be drawn between the radio development of RS Ophiuchi and that of young supernovae.

In both recurrent and classical novae, the outbursts may result from thermonuclear runaway on the surface of a white dwarf in a close binary system, which leads to a rapid increase in luminosity and mass ejection[1]. Based on this model there are two major differences between recurrent and classical novae. First, the secondary component of the binary system in recurrent novae is thought to be a late-type giant rather than a main-sequence dwarf as in classical novae. Second, the inter-outburst timescale is tens of years rather than 10^4–10^5 years as predicted for classical novae; for example, the recurrent nova RS Ophiuchi has previously undergone very similar outbursts in 1898, 1933, 1958 and 1967 (ref. 2).

Following the nova outburst reported by Morrison[3] on 26 January 1985, observations were made with the new Jodrell Bank Mk IA, Mk II 400-MHz bandwidth interferometer system operating at 5 GHz (S.P. and R.J.D., in preparation). This instrument has a baseline of 425 m, giving a lobe spacing of ~30 arc s at 5 GHz. At this frequency, the 4-arc min beam of the Mk IA telescope results in a typical confusion level of 1 mJy. The first flux density measurement of RS Ophiuchi was obtained on 13 February, only 18 days after the outburst. This first detection yielded a flux density of 23 ± 3 mJy and subsequent observations on 15 February revealed an increase in flux density[4].

Phase measurements made with the interferometer allow the position of the radio emission to be established to within ±2 arc s in right ascension and ±4 arc s in declination; within these limits the radio position was found to be consistent with the reported optical position of the nova. Figure 1 shows observations of the radio 'light' curve at 5 GHz for RS Ophiuchi between 13 February and 5 March. Further observations were not possible because of telescope scheduling considerations. The flux density calibration of these data is based ultimately on observations of 3C286, which is assumed to have a flux density of 7.30 Jy at 5.0 GHz (ref. 5), with the gain-elevation dependence of the interferometer being obtained from observations of many different radio sources. For all these observations, a referencing technique was used with the instrument observing a nearby calibrator source for a short time before moving to the field of interest. Using such a procedure, the flux density of the nova is accurately related to that of the source 1741–038 and this is reflected in the relative error bars in Fig. 1. However, the flux density of 1741–038 is not accurately known and so this has been related to 3C286. This latter calibration introduces a further systematic error of ~5% into the flux density scale.

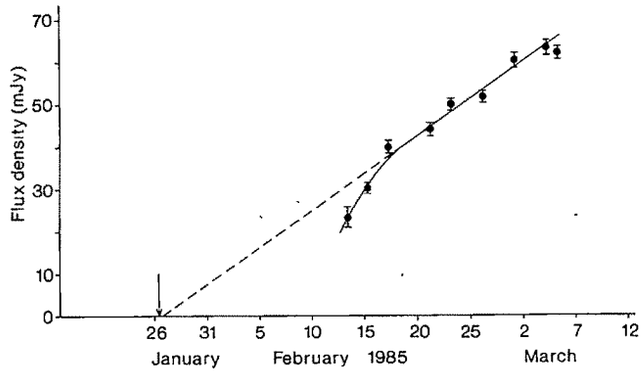

Fig. 1 Radio 'light' curve for the recurrent nova RS Ophiuchi measured at 5 GHz with left-hand circular polarization. The vertical arrow indicates the time of the optical outburst.

Figure 1 clearly shows two phases in the radio development of the nova. Initially there is a rapid increase in flux density at a rate of approximately 4 mJy per day until 18 February; this then gives way to a slower linear increase which projects back to the time of the initial outburst (t_0), giving a $(t-t_0)$ dependence with a constant of proportionality of 1.7 mJy per day. This $(t-t_0)$ dependence is characteristic of the classical radio novae observed by Hjellming *et al.*[6]. The initial rapid rise indicates that the radio emission 'turned on' about 14 days after the nova explosion, but after a further 10 days it reached the $(t-t_0)$ curve. Thus, although the radio emission was 14 days late in turning on, after ~24 days the curve proceeds as if the emission had started at t_0.

Analogies may be drawn between the radio development of RS Ophiuchi and that of Type II supernovae. In the latter case, the non-thermal radio emission is thought to arise from the interaction of an ejected shell with the pre-outburst wind of the late-type supergiant progenitor[7]. Similarly, RS Ophiuchi is thought to eject $\sim 10^{-5} M_\odot$ of material at $\sim 1{,}000$ km s^{-1} into pre-existing circumstellar material[8] which may be associated with a wind from the giant secondary of a binary system.

If we assume a distance of 2 kpc (ref. 9) and an average expansion velocity of 10^3 km s^{-1}, we calculate a brightness temperature of 10^7 K for the period of our observations. Initial measurements with the Very Large Array indicate a nearly flat spectrum (R. M. Hjellming, personal communication). Classical novae[6] exhibit thermal radio emission, typically with a temperature of 10^4 K, and during the optically thick, rising phase of the light curve have a spectral index of ~+1.5. These differences lead us to suggest a non-thermal origin for the radio emission in RS Ophiuchi. As the $(t-t_0)$ dependence is similar to that of a classical nova, albeit with a different constant of proportionality, these observations suggest that both the optical depth and dynamics of the shell after 24 days may be similar for the two phenomena, even though the radio emission mechanism may differ. The subsequent radio evolution of this system is clearly of considerable interest.

We thank R. M. Hjellring, A. Evans and F. D. Kahn for providing data in advance of publication and for helpful discussions. S.P. and M.F.B. are grateful to the SERC for a Research Studentship and an Advanced Fellowship.

Lower stratosphere trace gas detection using aircraft-borne active chemical ionization mass spectrometry

F. Arnold & G. Hauck

Max-Planck-Institut für Kernphysik, Postfach 103980, D-6900 Heidelberg, FRG

Acetaldehyde and acetone are expected to be formed as trace gases in the free troposphere from photochemical conversion of non-methane hydrocarbons and to represent key precursors of peroxy-acetyl nitrate (PAN)[1–5]. PAN is important as a potential organic reservoir[1–5] for odd N and thus as a vehicle for odd N transport in the troposphere or even from the troposphere to the stratosphere. As PAN suffers from thermal decomposition in the lower troposphere, its transport into the stratosphere relies on its formation in the upper troposphere where temperatures are sufficiently low to prevent thermal decomposition. Neither PAN nor its key precursors, however, have been observed in the free troposphere and it is difficult, therefore, to assess the potential impact of non-methane hydrocarbons on upper tropospheric and stratospheric ozone[1–5]. An indication of the presence of acetone around the tropopause level was first obtained recently from ambient positive-ion composition measurements[6]. Here, we report on a search for these trace gases and other species with large proton affinities in the tropopause using aircraft-borne active chemical ionization mass spectrometry (ACIMS), a novel method for atmospheric trace gas detection.

The ACIMS method developed in our laboratory will be described in detail elsewhere[7,8] and only a brief outline is given here. Detection by ACIMS of molecules B possessing large proton affinities or gas phase basicities relies on their reaction with $H_3O^+(H_2O)_n$ ions in

$$H_3O^+(H_2O)_n + B \rightarrow HB^+(H_2O)_n + H_2O \quad (1)$$

Usually[8] proton transfer reactions (1), if sufficiently exothermic, occur on every collision and have a temperature-independent rate coefficient of $\sim 2\text{–}5 \times 10^{-9}$ cm^3 s^{-1} depending on the dipole moment of B. The ACIMS apparatus (Fig. 1) works like a flow reactor where ambient air is sampled by an air intake on top of the aircraft's fuselage and then the air stream is passed through a flow tube and directed to the sampling cone of a cryogenically pumped quadrupole mass spectrometer. Ultimately, the air stream leaves the aircraft's fuselage through an outlet tube. Precursor ions $H_3O^+(H_2O)_n$ are formed by a high-frequency glow-discharge ion source inside the flow tube, 70 cm upstream of the sampling cone that carries the inlet orifice through which ions enter the mass spectrometer. The time t_R for which ions reside in the reaction zone between the ion source and the sampling cone, being typically 17 ms, can be measured precisely by pulsing the ion source and measuring the ion arrival time. By measuring the flux ratio $F(HB^+)/F(H_3O^+)$ for precursor and product ions with the mass spectrometer, the [B] can be obtained using expression

$$[B] = \frac{1}{kt_R} \ln\left(\frac{F(HB^+)}{F(H_3O^+)} + 1\right) \quad (2)$$

which follows from integration of the kinetic equations for product and precursor ions.

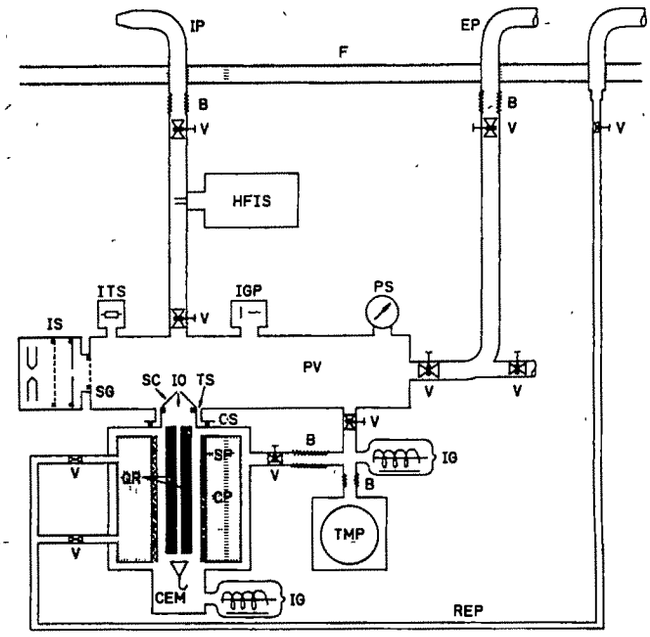

Fig. 1 Schematic representation of the aircraft-borne chemical ionization mass spectrometry apparatus. F, fuselage; IP, intake pipe; EP, exit pipe; V, valve; HFIS, high-frequency glow-discharge ion source; IS, electron impact ion source; ITS, temperature sensor; IGP, ion getter pump; PS, pressure sensor; SG, sampling grid; PV, probing vessel; SC, sampling cone; TS, Teflon seal; IO, inlet orifice; OS, O-ring seal; QR, quadrupole rods; CP, cryo-pump; SP, sorption panel; B, bellow; IG, ionization gauge; TMP, turbomolecular pump; CEM, channel electron multiplier.

Taking the above k and t_R and an ion flux ratio of 0.001 which can easily be measured, a conservative estimate for the typical detection limit of $\sim 3 \times 10^7$ cm^{-3} corresponding to a volume-mixing ratio of $\sim 4 \times 10^{-12}$ or 4 p.p.t.v. (parts per trillion by volume) at $\sim$11,000 altitude is obtained. The uncertainty in [B] is determined primarily by the uncertainty in k, which may be as low as ±30% in laboratory measurements. Typical uncertainties for t_R and the ion flux ratio are both ±20%. Taking a typical uncertainty for k of ±50%, an estimate of the overall uncertainty for [B] of ± ~57% is obtained. The precision of [B], which is not affected by the uncertainty in k, is ± ~28%.

The first flight of the novel ACIMS instrument was on 24 February 1984 over the FRG, reaching a maximum altitude of

Table 1 Concentrations and volume mixing ratios for trace gases measured in flight F5 at 11,300 m

Molecule	PA (kcal mol^{-1})	k (10^9 cm^3 s^{-1})	Concentration (10^{-8} cm^{-3})	VMR (10^{12})	Other data		Ref.

PA, proton affinities (see ref. 9); VMR, volume mixing ratios. References are for other data.

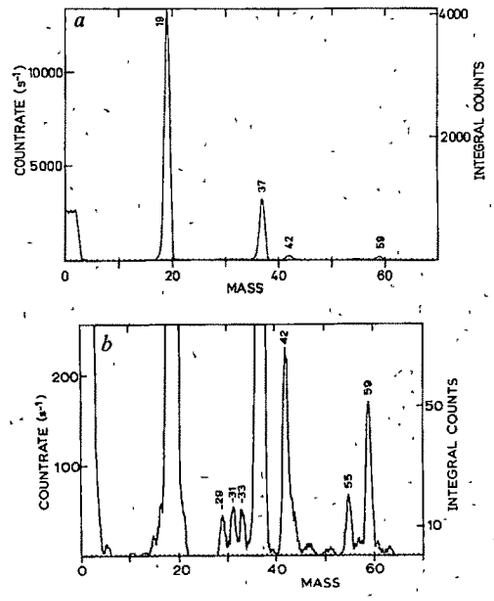

Fig. 2 *a*, Positive-ion ACIMS mass spectrum obtained at 4,300-m altitude. Panel *b* is enlarged in the *y*-direction for visualization of minor ion peaks. The signal at masses 0–4 does not represent a mass peak but is a reduced total ion signal occurring at very low radiofrequency-amplitude of the mass filter. Integral counts denotes the total number of ion counts per mass peak.

11,300 m, well above the local tropopause levels (9,750–10,360 m) and cloud-top levels (5,000–8,000 m). ACIMS measurements were taken only at 11,300 m and only for a short period of time (15.19–15.33 LT) and the remaining flight time was spent for ambient ion composition measurements[6].

A typical positive-ion ACIMS spectrum, obtained in 40 s at 11,300 m, is shown in Fig. 2. Besides the precursor ions $H_3O^+(H_2O)_n$ (masses 19, 37, 55), it contains several product ion peaks of which 42 and 59 are most prominent. Like H_3O^+, the most prominent member of the $H_3O^+(H_2O)_n$ family, these ions must be naked 'cores' of the type HB^+, with B possessing a large proton affinity (typically $> \sim 175$ kcal mol^{-1}). Therefore, the most probable candidates are protonated acetonitrile (42) and protonated acetone (59); no significant peaks attributable to protonated acetaldehyde (45) and protonated ammonia (18) occur.

Taking measured rate coefficients k (Table 1), concentrations (acetonitrile and acetone) and upper limits (ammonia and acetaldehyde) were obtained from equation (2). A compilation of our measured trace gas abundances is given in Table 1 together with other data. (Data for additional trace gases detected by the present ACIMS experiments are given elsewhere.)

Our present acetonitrile abundance of 36 p.p.t.v. at 11,300 m is similar to the average ground-level value of 56 p.p.t.v. obtained by Snider and Dawson[13] (Fig. 3), which suggests that acetonitrile has a sufficiently long lifetime to allow for efficient vertical mixing in the troposphere (typical timescale: several days). This is consistent with recent estimates of CH_3CN-lifetimes against reaction[18] with OH and washout[19] being about 1–2 years in the troposphere. In contrast, middle stratosphere acetonitrile mixing ratios as obtained from balloon-borne PACIMS (passive chemical ionization mass spectrometry) measurements[11,17] are much lower than our present value at 11,300 m, which is somewhat surprising in view of the relatively slow reaction of CH_3CN with OH, the only presently known CH_3CN-sink in the lower stratosphere. A one-dimensional photochemical model calculation of CH_3CN by Brasseur *et al.*[18] (also shown in Fig. 3) considering reaction with OH as the only CH_3CN-sink requires a tropospheric CH_3CN-volume mixing ratio of only 10 p.p.t.v. in order to reproduce the middle stratosphere observations. Compared to this value our present measured value of 36 p.p.t.v. and the average ground-level value of 56 p.p.t.v. are much larger.

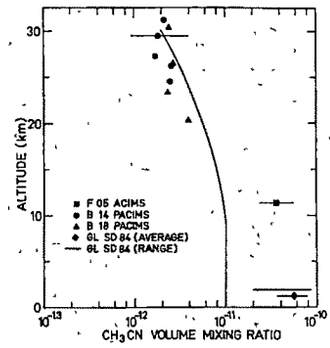

Fig. 3 Comparison of measured acetonitrile volume mixing ratios as obtained from aircraft-borne PACIMS[11,17] and ground-level (GL) condensation collection[13]; typical error bars for the various analytical methods are indicated. Also shown is a one-dimensional photochemical model calculation for CH_3CN by Brasseur *et al.*[18] considering reaction with OH as the only CH_3Cn-sink.

The reason for this discrepancy is presently not known. Possibilities include an additional lower stratosphere CH_3CN-sink or a non-uniform tropospheric CH_3CN-distribution with lower abundances in equatorial regions where tropospheric air primarily enters the stratosphere. However, it should be kept in mind that the stratospheric distribution of CH_3Cl, which is also removed by reaction with OH at a rate similar to CH_3CN and which is practically uniformly mixed in the troposphere, is not well reproduced by one- and two-dimensional model calculations. Usually stratospheric CH_3Cl is overestimated by the models[22]. Concerning additional CH_3CN-sinks in the lower stratosphere the possibility of CH_3CN-removal by ion processes may also be considered in view of the fact that stratospheric positive ions contain CH_3CN. Upon ion–ion recombination of such CH_3CN-containing clusters, CH_3CN may be destroyed by reaction or be incorporated into aerosols which may eventually result from ion–ion recombination[20,21]. However, very little is known about the products of ion–ion recombination and thus the possibility of CH_3CN-removal by ions remains speculative.

Compared with acetonitrile the situation for ammonia is entirely different. Here, the upper limit of 73 p.p.t.v. is much lower than the upper troposphere and lower stratosphere measurements yet made. Only two measurements at $\sim$11,000 m have been reported (2 p.p.b.v., March 1979; 0.6 p.p.b.v., August 1979)[14] using a remote infrared heterodyne radiometer technique. Our value is also much lower than the chemical filter data (0.6 p.p.b.v.) obtained[15] at $\sim$4,000 m. Again, more free tropospheric measurements covering a range of meteorological conditions are needed before conclusions on ammonia transport and removal can be reached.

We next discuss acetone and acetaldehyde. The present acetone abundance of 25 p.p.t.v. is higher than the model predictions of Singh and Hanst[1], being 15 p.p.t.v. (9,000 m) and 3 p.p.t.v. (15,000 m). By contrast, the upper limit described here for acetaldehyde of 2 p.p.t.v. is somewhat lower than the model predictions[1] (3 p.p.t.v., 9,000 m; 7 p.p.t.v., 15,000 m). If the kinetic data used by Singh and Hanst[1] are correct, PAN formation at 11,300 m from acetone would be at least 10 times more efficient than from acetaldehyde. A further implication is that the production of acetone would be much larger than predicted by the model (considering only propane as a precursor of acetone). Thus, either the propane level was higher than assumed or additional non-methane hydrocarbon species contribute significantly to acetone formation. It is also conceivable that the observed increase in acetone level is associated with jet aircraft exhaust, a possibility that deserves further attention. Alternatively, the model may underestimate the lifetime of acetone in the troposphere.

Clearly, more measurements, in particular height profiles, of acetone, and eventually also acetaldehyde, in the free troposphere and lower stratosphere are needed to elucidate the details of PAN formation in this part of the atmosphere. The ACIMS method has the potential to contribute significantly to an

improved understanding of the photochemistry of non-methane hydrocarbons in the free troposphere and lower stratosphere.

We thank E. E. Ferguson, P. Crutzen, D. Ehhalt, D. Griffith, U. Schmidt and J. Rudolph for discussions and the technical staff of the MPI-K (in particular K. Oberfrank) and the Abteilung Flugbereitschaft of the Deutsche Forschungs und Versuchsanstalt für Luft und Raumfahrt, for support. This project was funded by the Bundesministerium für Forschung und Technologie through Gesellschaft für Strahlen und Umweltforschung.

An Antarctic ice core reveals atmospheric CO_2 variations over the past few centuries

D. Raynaud & J. M. Barnola

Laboratoire de Glaciologie et Géophysique de l'Environnement, BP 96, 38402 St Martin d'Hères Cedex, France

When snow is transformed into ice (firnification process) by sedimentation near the surface of an ice sheet, some of the atmospheric air is trapped in the inter-grain spaces which are progressively isolated from the surrounding atmosphere. The resulting material is an air-tight bubbly glacial ice. By analysing the air extracted from the bubbles found in the ice, it is possible to determine the air composition and thus its CO_2 content for the period during which the air was trapped. We aim here to provide the most direct evidence obtained so far for the background atmospheric CO_2 concentrations over the centuries preceding the recent anthropogenic perturbation due to the industrial revolution of the past century. This background level is important for assessing both the origin and the climatic response of the anthropogenic perturbation to the atmospheric CO_2 (see ref. 1). Our results, obtained from the analysis of the air trapped in the bubbles of an Antarctic ice core, indicate that the background level could have been as low as 260 p.p.m.v. (parts per million by volume) before the major anthropogenic influence and suggest that the so-called 'pre-industrial' CO_2 level was not constant over the few hundred years preceding the nineteenth century.

Although several parameters, such as snow melting at the surface of the ice sheet, may obscure the record, CO_2 results representing the atmosphere can be obtained with a good degree of confidence by choosing appropriate sites, cores and gas extraction methods (see ref. 2). In particular, the best conditions are found using unfractured ice cores taken in the dry snow zones where no melting occurs (the mean annual air temperature of these zones is generally below −25 °C). The ice record of atmospheric CO_2 against time is, furthermore, 'smoothed' because each ice layer contains bubbles which closed off at different times during the firnification. Because the firnification rate increases with the rate of snow accumulation at the surface, a low smoothing effect is expected in high-accumulation sites. For this study, the smoothing must be as low as possible to detect, with sufficient definition, the possible atmospheric CO_2 changes over a few centuries. In short, we are looking for a good core taken in a cold site without summer melting and with a high accumulation rate.

Such requirements were fulfilled by a 203-m-long ice core drilled in 1980–81 at the station D57 (68°11′ S, 137°33′ E) in East Antarctica. The ice from this core analysed for the present study was formed, according to an ice origin calculation, upstream from the drilling site in a zone where the mean annual surface temperature is ≤−32 °C (−32 °C at D57) and the present-day measured snow accumulation rate is 45 cm of ice equivalent yr^{-1} at D57 and highly variable upstream (M. Pourchet, personal communication). Taking into account the accumulation data and the conditions of gas enclosure, each air sample analysed could average between ~20 and 40 yr of atmospheric conditions.

For CO_2 measurements, we sampled eight depth levels between ~89 and 198 m below the surface (Table 1). For each level, between 16 and 50-cm lengths of the ice core were analysed after the ice samples (weighing between 23 and 46 g) had been cut into horizontal core layers ~2–4 cm thick. These ice samples were taken from the internal and unfractured part of the ice cores and cut in a cold room (at about −15 °C) with a band saw. The whole experimental procedure, including all the steps between the extraction of the gas by grinding the ice under vacuum at −40 °C and the gas chromatographic analysis, was performed using the Grenoble method described in ref. 3.

For each measurement, the analytical system is calibrated as described in ref. 3 and the experimental accuracy (with a 95% confidence limit) is evaluated from the standard deviation of the residuals corresponding to the calibration regression. This accuracy for the results presented here is in the range ±1.1–4.8%. Between 5 and 13 samples were processed for each depth level. The corresponding CO_2 results are shown in Table 2. The scattering of the CO_2 measurements for a given depth level is evaluated by calculating their standard deviation and lies in the range ±1.3–3.8% (Table 1). This scattering is smaller than, or

Table 1 D57 ice-core sample characteristics, mean CO_2 concentrations and mean ages of the gas

197.2–197.5	24	6	3.4	271	1560	1340

The mean ages of the gas are calculated (see text) taking into account a constant rate of bubble enclosure between the densities 0.80 and 0.83 and ages of ice obtained from modelling the ice flow (*a*) and by assuming a constant accumulation rate of 18 cm of ice equivalent yr^{-1} (*b*).

similar to, the experimental errors and can consequently be attributed to them. The mean CO_2 concentrations measured for each depth level are shown in Table 1.

Our calibration gas has been compared with standards prepared according to the WMO 1974 provisional scale by the Scripps Institution of Oceanography[3] and the error due to the calibration gas on the absolute values of the CO_2 measurements is estimated to be $\leq \pm 1\%$. An absolute calibration of the complete procedure is, unfortunately, not possible because a standard ice enclosing bubble having a known composition is not available. Nevertheless, we recently simulated such a calibration by grinding artificial bubble-free ice surrounded by a volume of calibration gas equivalent to the volume of air trapped in the natural ice. The results indicate that the procedure does not change the CO_2 composition of the gas within experimental error. A similar conclusion has been reached after comparing CO_2 measurements on air from bubbles in polar ice performed in our laboratory and in the Physics Institute of Bern[3]. Nevertheless, more recent measurements made in Bern suggest that their results would have to be corrected by adding ~15 p.p.m.v. (ref. 4). A new comparison is in progress between the two laboratories to solve this uncertainty.

We will now evaluate when the air found in the bubbles was isolated from the free atmosphere. As pointed out above, the bubbles become isolated from the free atmosphere during the firnification process. Consequently, the gas at a given depth is younger than the ice itself. The bubble close-off process begins to be significant probably after the firn grains have been packed into the closest possible arrangement. This closest possible packing corresponds, according to Anderson and Benson[5], to a firn density of ~0.55. The enclosure process ends at the firn-ice transition, at a density of ~0.83. Recent volume measurements of the closed bubbles in the firn at Siple Station, Antarctica, by Schwander and Stauffer[6] indicate that 80% of the bubbles close off between the densities 0.795 and 0.83. Nevertheless, the observed occurrence of impermeable layers and the fact that the air, especially in the deeper part of the firn, could not be well mixed with the atmosphere, may isolate the air in the firn from the free atmosphere at shallower firn densities (and consequently at shallower depths). Furthermore, although the experimental method used by Schwander and Stauffer is the best available, we believe that this method risks breaking some bubbles near the sample surface. If this is the case, the method provides a minimum volume value of the closed bubbles, especially for the firn with relatively low densities. Also, the enclosure conditions could be different at D57 because the firnification parameters (temperature and snow accumulation rate) are not the same as at Siple Station. For these reasons we assume that: (1) the bubbles close off at a constant rate between the densities 0.80 and 0.83 which correspond, respectively, to depths of ~68 and 76 m below the surface at D57; and (2) the air can be isolated before the firn reaches the density 0.80. Taking into account the time of deposition of the snow at the surface of the ice sheet, that is, the age of the ice, and the time required to reach the densities 0.80 and 0.83, it is possible to calculate mean ages of the air samples we analysed. These gas ages are given in Table 1 and Fig. 1 for two different estimates of the age of the ice. They may be, in fact, older by several tens of years, as suggested by the arrows in Fig. 1, because the air can be isolated before the firn reaches the density 0.80. This uncertainty would be, in the case of D57, generally smaller than the uncertainty in the determination of the age of the ice.

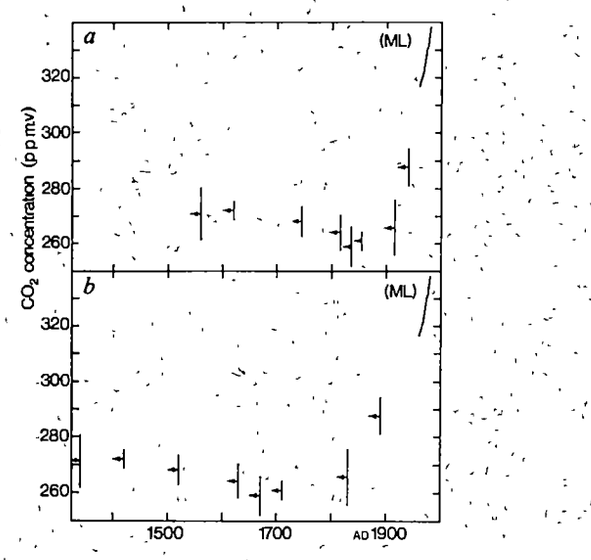

Fig. 1 Atmospheric CO_2 concentrations during the past centuries as deduced from the D57 ice-core analysis. The vertical lines indicate the scattering ($\pm 1\sigma$) of the measurements. The mean ages plotted were obtained using two different approaches (see text). *a*, Dating of the ice obtained by modelling the ice flow. *b*, Dating based on the Tambora horizon at a depth of ~48–50 m below the surface and on a constant snow accumulation rate for the whole period encompassed by the core. The arrows indicate qualitatively that the mean ages may be older if the air in the firn is isolated from the atmosphere before the firn reaches the density 0.80. ML, The atmospheric CO_2 record since AD 1958 at Mauna Loa[10].

For dating the ice, we have used two approaches. First, the depth–age relationship has been calculated (C. Ritz and D.R., unpublished data) from modelling the ice flow upslope from D57 by assuming a uniform vertical strain rate and horizontal ice velocities independent of the depth. The parameters required for the calculation include snow accumulation rate, horizontal ice velocity and ice thickness at the sites of snow deposition. The times required for the snow to reach the densities 0.80 and 0.83 have been obtained in a similar way. This dating depends essentially on snow accumulation data. Unfortunately, the accumulation rate pattern upslope from D57 is highly variable and poorly known. In this calculation, we take into account the limited accumulation rate data available: 45, 32, 4.4, 15, 34 and 28 cm of ice equivalent at D57 and 10, 15, 16, 20 and 33 km upslope from D57 respectively (M. Pourchet, personal communication). These data are representative of between 4 and 28 yr of present-day accumulation. The mean age of the gas corresponding to this approach is shown in Table 1 and Fig. 1*a*. The second approach takes into account two exceptionally marked sulphate horizons recorded at 48 and 50 m below the surface[7]. According to Legrand and Delmas (personal communication) (1) these two horizons are undoubtedly volcanic and have also been recorded in the Dome C and South Pole cores

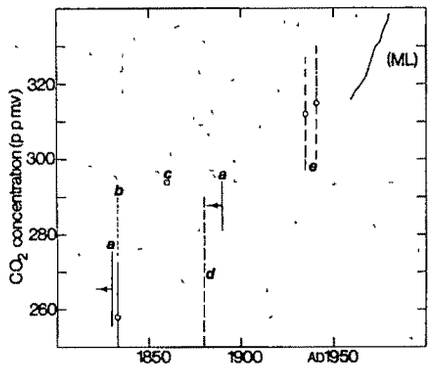

Fig. 2 Comparison between the CO_2 results from the D57 ice core and other estimates for the period since AD 1830. For the D57 results (*a*) only those ages in Fig. 1*b* for which we have most confidence for this time period are plotted. *b*–*e*, Estimates of past atmospheric CO_2 concentrations (discussed in refs 8 and 9) based on: *b*, the analysis of sub-surface ocean waters; *c*, a model calculation extrapolating from ML by assuming fossil-fuel combustion to be the only source of CO_2; *d*, the interpretation of some early chemical measurements of atmospheric CO_2; and *e*, preliminary analyses of archived solar spectra. ML is the atmospheric CO_2 record observed at Mauna Loa since AD 1958 (ref. 10).

which are independently datable with much more confidence than the D57 core; (2) the most likely candidate for one of these events is the Tambora eruption, AD 1815. This AD 1815 level at ~48–50 m below the surface would correspond to a mean accumulation rate of ~18 cm of ice equivalent yr^{-1} during the past 165 yr. We have tentatively calculated (Table 1) and plotted in Fig. 1*b* what would be the mean age of the gas if the accumulation rate remained constant at this value for the whole time period encompassed by the core. The two approaches give important differences (from 50 to 220 yr) in the mean age of the gas for the levels measured in CO_2. This clearly demonstrates the large uncertainties in the dating of the gas trapped in the D57 core. Nevertheless, the sulphate horizons found at 48 and 50 m below the surface are an important constraint for the dating of the upper part of the core and consequently, for the youngest part of the CO_2 record, we have more confidence in the timescale shown in Fig. 1*b*.

Whatever the dating uncertainties, this first detailed CO_2 record over the past few centuries from ice-core analysis indicates (Fig. 1) that the atmospheric CO_2 concentrations were at a minimum some time between AD ~1650 and 1850, with a mean value of ~260 p.p.m.v. This value must be compared with the ~295 p.p.m.v. calculated for the pre-industrial level (AD 1860 and before) by extrapolating observed CO_2 values from 1958 to the present and assuming that fossil fuels were the only sources[8,9]. The difference between the measured values from the D57 core and the results of this calculation strongly suggests that another important source has been active during the period preceding any significant use of fossil fuels, even if we have to correct systematically the measured values by +15 p.p.m.v. Taking into account the two youngest CO_2 levels plotted on Fig. 1*b* against the age that we favour for this part of the record, the main origin of this source may very well be the agricultural 'revolution' which began seriously to modify the biosphere during the past century.

Another interesting feature of the D57 core is, as shown in Fig. 1, that a mean decrease of the order of 10 p.p.m.v. may have occurred over a period of a few centuries before AD 1800. This fluctuation may reflect natural changes in the biospheric and/or oceanic CO_2 reservoirs which are possibly linked with the suggested worldwide Little Ice Age. This result suggests that the so-called 'pre-industrial' CO_2 level was not constant even over the few centuries preceding the important anthropogenic perturbation of the various CO_2 pools.

In the search for the atmospheric CO_2 level during pre-industrial times (before AD 1860, and on the scale of a few centuries), other kinds of records have been used, including the chemical measurements of atmospheric CO_2 performed during the second part of the nineteenth century, the $\delta^{13}C$ record of tree rings, and the chemical analysis of sub-surface ocean waters. A recent critical review[8,9] of the different types of record of the atmospheric CO_2 concentrations from pre-industrial times to 1958 concluded that CO_2 analysis of the ice cores currently seems to be the best, and most direct, method of determining the atmospheric CO_2 concentration before AD 1900. We can consequently consider that the D57 results presented here provide a most representative record of the atmospheric CO_2 background level for the 'pre-industrial' period.

Finally, the D57 record is also the first ice-core analysis to indicate clearly the increase in atmospheric CO_2 due to the burning of fossil fuels and probably also due to the anthropogenic influence on the biosphere over the nineteenth and twentieth centuries. Figure 2 shows this increase as recorded in the D57 core since AD ~1850, compared with other estimates discussed in refs 8 and 9.

This research was supported by the European Economic Community, Programme Interdisciplinaire de Recherche sur l'Environnement, Terres Australes et Antarctiques Françaises and Expéditions Polaires Françaises. We thank C. Ritz for help in dating the D57 core and R. Delmas, M. Legrand, C. Lorius and M. Pourchet for helpful discussions, also B. Stauffer for useful comments.

Structure of the ammonia synthesis catalyst

T. Rayment, R. Schlögl† & J. M. Thomas*

Department of Physical Chemistry, University of Cambridge, Lensfield Road, Cambridge CB2 1EP, UK

G. Ertl

Institut für Physikalische Chemie, Universität Munchen, 8000 München, FRG

The synthesis of ammonia from hydrogen and nitrogen over a reduced iron oxide catalyst is so well known[1–5] and so widely used (current world capacity is close to 100×10^6 tons per year) that it may seem surprising that the mode of operation of the catalytic remains enigmatic. That both H_2 and N_2 must first dissociate at the catalyst surface is beyond dispute, but there is debate as to the role of various promoters (Al, K, Ca) which greatly improve the catalytic performance when added to the precursor Fe_3O_4. Although it is widely accepted that regions of paracrystallinity exist within the catalyst, no one has questioned its overall crystallinity. In this work, which entails *in situ* X-ray diffractometry, we provide evidence that the active catalyst contains substantial amounts of a non-crystalline phase. Without promoter, reduction of Fe_3O_4 in the same conditions yields only crystalline α-iron.

Even though there have been more than 100,000 catalyst formulations for the synthesis of ammonia, the catalyst of choice still remains that selected for the original Haber–Bosch process,

* To whom correspondence should be addressed
† Present address: Institut für Physik, Universitat Basel, Basel, Switzerland

promoted iron. How do these promoters exert their influence? The likely role[6] of the alkali is to facilitate the dissociative chemisorption of nitrogen, the rate-determining step. The present consensus view[5,7] on the role of alumina is that it serves as a textural promoter by stabilizing the α-iron phase, and preventing it from sintering, after its formation by reduction in the reactant gas stream, from the fused oxide precursor. In particular, it has been argued[8] on the basis of *ex situ* X-ray diffraction studies, that individual spinel units ($FeAl_2O_4$) are built into the active α-Fe catalyst and that these units cause internal strain giving rise to the formation of so-called paracrystals. This paracrystalline state is characterized by slightly broadened X-ray diffraction lines, a fact confirmed recently in another study[9]. Note, however, that these investigations were performed with reduced catalysts which had been re-oxidized before the measurements. Model studies with iron single crystal surfaces revealed the highest activity for the (111) surface plane[10], and the highest rate of nitrogen chemisorption is exhibited by this plane[11]. The presence of potassium, however, was found to eliminate the activity differences between various crystal planes (without affecting their structures)[6]. In view of these findings, discussions as to which crystallographic faces of iron are chiefly involved in ammonia synthesis at real (that is, promoted) catalyst become less cogent. This will be underlined by the present results which shed new light on the structure of the catalyst in working conditions. They also prompt us to re-examine the accepted picture that the function of the Al_2O_3 promoter is to stabilize the α-Fe phase in the synthesis catalyst. The evidence suggests that the active state of the promoted iron catalyst could be non-crystalline. The catalyst possesses essentially no long-range atomic order in reaction conditions. Our results also show that a typical promoted catalyst precursor contains at least five distinct crystalline phases before reduction.

The experimental evidence has been acquired using, principally, *in situ* X-ray powder diffractometry, rendered possible by adapting a commercial cell[12], capable of repeated rapid and slow scans of 2θ (scattering angle) operating at temperatures of up to ~550 °C and pressures of up to 1 bar. This set-up, which readily permits data accumulation, is a more sensitive apparatus than earlier versions[13] and is capable of operation at temperatures higher than those explored, also *in situ*, by Mosesman[14]. Other measurements involving Mössbauer spectroscopy, physical adsorption, kinetic studies of ammonia formation rates at high pressure as well as a range of electron microscopic techniques all point to the catalytically active phase of iron being amorphous, in the sense that splat-cooled metals and alloys are amorphous. Full details of our work will be presented elsewhere. Here we concentrate on the results of the X-ray studies that have been carried out on typical industrial ammonia synthesis catalysts (provided by BASF (catalyst number MUC) and ICI).

The X-ray diffractogram for typical promoted BASF and ICI unreduced catalysts containing 2% Al_2O_3, 2% CaO and 0.5% K_2O shows predominantly *hkl* reflections for Fe_3O_4. However, a diffractogram which took ~100 h of recording time and involved three separate specimens with overlapped regions of 2θ (owing to suspected X-ray-induced radiation damage) shows the presence of a large number of weak diffraction peaks arising from minority phases. Analysis of such multiphase mixtures is not straightforward, and an unambiguous assignment using solely the diffractograms and the Joint Committee on Powder Diffraction Studies data file is not possible. When combined with knowledge of the known chemistry of Fe/Al and Ca/Fe oxides and previous information concerning the presence of CaO in promoted catalysts, the minority phases so identified were: $FeAl_2O_4$, $FeAlO_3$, CaO and $K_2Fe_{22}O_{34}$. Alternative assignments are possible, and could, for example, include $CaFe_3O_5$ and $KHCO_3$, but the presence of the bicarbonate can be safely discounted since there is no (analytically measurable) carbon present in the catalyst.

Unpromoted catalysts yielded diffractograms containing reflections from Fe_3O_4 only. When these unpromoted catalysts were heated in 1 bar H_2 (30 cm^3 min^{-1}) up to 500 °C, the resulting diffractogram, recorded at this temperature with the catalyst still exposed to the H_2 atmosphere, revealed (Fig. 1) peaks attributable to α-Fe.

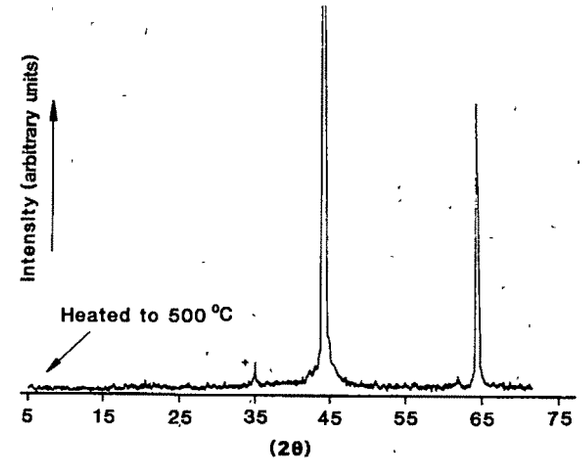

Fig. 1 Diffractogram (recorded at 500 °C) of unpromoted magnetite catalyst that had been heated in 1 bar H_2 up to 500 °C. The main peaks are attributable to α-iron. (The peak marked + is a spurious reflection from the high-temperature attachment.)

When the diffractograms were recorded with the promoted catalysts exposed to N_2 at a pressure of 1 bar and at temperature up to 500 °C, they were indistinguishable from the patterns of the starting material. Dramatic changes in the diffractograms were, however, seen when the promoted catalysts were heated in either 1 bar of H_2 or 1 bar of $3H_2:1N_2$ mixture (Fig. 2). At ~425 °C for the BASF catalyst and at ~460 °C for the ICI catalyst, very broad diffraction peaks (~10 times as wide as those previously reported[8,9] for paracrystalline iron) were obtained.

These diffraction patterns are very different from those expected for finely divided or paracrystalline α-iron. No intense reflections are observed, but instead there are a series of weak and broad features. The most surprising feature is a broad diffraction peak at 2θ ~25°. There are no allowed diffraction lines for αFe at this angle and hence it cannot be interpreted in terms of extremely finely divided crystalline iron. Experiments monitoring the weight loss during reduction confirm that the material is essentially fully reduced (±1%) during our experiments and so the features displayed must be caused by a phase

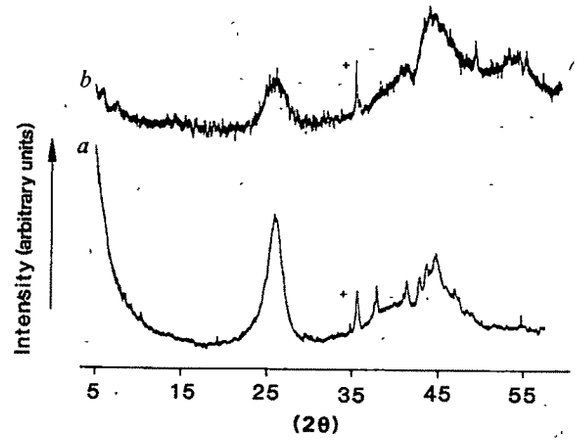

Fig. 2 Typical diffractograms of reduced promoted magnetite catalysts. *a*, Heated to 500 °C; *b*, subsequently cooled to 400 °C. These broad diffraction peaks are much wider than any previously reported (see text). A new rather broad peak (at 2θ ~25°) also appears irrespective of whether the reduction is carried out, at 1 bar, in either H_2 or $3H_2:1N_2$. The sharp peaks superimposed on the broad background arise chiefly from small particles of crystalline $FeAlO_3$. (The peak marked + is a spurious reflection from the high-temperature attachment.)

which contains predominantly iron. The shape of the peak at 2θ 25° seems to depend on the conditions used during reduction (the temperature and gas flow), but we will not consider this in detail here because the effects may be obscured by the deviations from parafocusing caused by the sample expansion, and by the tendency for the sample to fall off. The diffraction pattern shows a striking similarity to that of some glassy metal alloys such as Fe/Ni/B which display a broad diffraction feature at 2θ ~24° when doped with a small quantity of silicon[15]. The simplest explanation of the data observed here is the formation of an amorphous iron-containing phase which is stabilized by the incorporation of small quantities of dopants that may arise from the promoter additives or from residual oxygen.

It is also possible to propose more complex assignments for the data, based on the fact that the broad feature at 2θ ~45° arise from allowed diffraction peaks of αFe. Thus, microcrystalline particles of αFe (~20 Å diameter) may be present together with an additional new phase of iron giving rise solely to the peak at 2θ 25°. Evidence for this view is less compelling than the simpler explanation that the material is amorphous. Whilst the diffraction pattern is dominated by the 'amorphous' features, the presence of some residual crystalline phases is indicated by small but comparatively sharp peaks in the region of 2θ from 35° to 55°. These have been identified as arising for the most part from $FeAlO_3$. Through the viewing port of the X-ray camera, the promoted catalysts were seen to expand rapidly during the reduction in H_2 at elevated temperature, a fluffy black powder resulting after the expulsion of water. These changes occurred concomitantly with the changes in crystallinity, detected by the repeat-scan X-ray diffractometry.

The diffractogram in Fig. 2*a* was recorded over an 18-h period with the sample exposed to 1 bar H_2 at 500 °C. The essential features of this diffractogram are obtained with the catalyst exposed to $3H_2:N_2$ mixtures at elevated temperature (~425 °C) and are retained when the catalyst is cooled to room temperature in a non-oxidizing (H_2 or H_2–N_2 mixture) atmosphere. The catalyst spontaneously oxidizes on exposure to air even at room temperature and forms Fe_3O_4 indistinguishable from the non-reduced precursor. Other measurements (and all handling) were, therefore, carried out under a nitrogen atmosphere.

That this non-crystalline, reduced iron can be a catalytically active phase was confirmed by kinetic measurements ($3H_2:1N_2$ at total pressure of 9 bar in the temperature range 350–450 °C). At 400 °C, conversion rates were ~10 μmol of NH_3 per g of catalyst per s. This amorphous catalyst, nevertheless, retained some morphological texture, possibly because the coexisting microcrystalline $FeAlO_3$ there consist of numerous platelets (~200 Å dimensions); and, by transmission electron microscopy, we observed some mesopore structure. This is reminiscent of the small particles (~300 Å diameter) seen[16] by scanning electron microscopy. No Mössbauer signal could be obtained[17,18] in conditions which yielded clear signals from other iron-containing catalysts: this is what one expects from a catalyst that is more similar to a glass than a solid.

Our *in situ* X-ray diffractometric studies show that a promoted ammonia synthesis catalyst produced by reduction in hydrogen is largely non-crystalline interspersed with microcrystals of $FeAlO_3$ and other promoter phases.

Whilst more work remains to be done to elucidate the nature of the non-crystallinity, the precise effects of water vapour and the influence of $FeAlO_3$ during the reduction[7,9], it is clear that the degree of coordination of a surface Fe atom in the catalyst, and the apparently central role assigned to (111) faces, needs to be reconsidered.

If the main phase in the active promoted catalyst is not pure elemental iron and impurities such as promoter additives or residual oxygen in a total concentration of ~1% permit the formation of a disordered phase distinctly different from a material containing small particles of crystalline αFe, many of the numerous other catalyst formulations previously discarded could, in appropriate conditions of preparation, turn out to be very efficient.

Liquid-phase polymer-based retention — the separation of metals by ultrafiltration on polychelatogens

The importance of trace-element analysis in geological, biological, environmental and industrial processes has been increasingly recognized. Although modern instrumental methods of analysis have been applied, preliminary enrichment techniques are required to separate the components to be determined from the interfering constituents of the sample[1,2]. For the separation of inorganic ions contained in natural waters, industrial fluids or dissolved solid materials, solvent extraction, sorption, ion exchange, precipitation and other methods have been used. However, techniques based on a two-phase distribution or on heterogeneous reactions often cause problems because, in contrast with homogeneous reactions, diffusion controlled processes must be used. Until now, no simple, rapid method has been available for the preconcentration and separation of metals in the homogeneous aqueous phase. Here we demonstrate a technique for the enrichment and separation of metals in aqueous solution using soluble non-crosslinked polymers with chelating groups (polychelatogens)[3,4] called liquid-phase polymer-based retention (LPR).

A variety of water-soluble polymeric reagents with strong complexing properties have been synthesized and used, in combination with membrane filtration, to separate complex from non-complex metal ions in the homogeneous phase. The LPR method is based on the retention of metal ions by a membrane which separates macromolecules from low relative molecular mass compounds as the complexes form with the polymer from a sample solution.

The experimental arrangement is outlined in Fig. 1. The system consists of the membrane filtration cell, containing the polychelatogen solution, to which the sample is added. For separation and enrichment, the washing solution is passed to the cell from reservoir I under stirring. The filtrate contains all the metal ions which are not retained as macromolecular complexes by the polymer reagent. Large volumes of very diluted samples are first enriched in respect to metals of interest by passing the solution from reservoir II to the much smaller volume of cell solution. Thereafter, the additional separation process is carried out by adding washing fluid from reservoir I to remove non-bound metals from the cell.

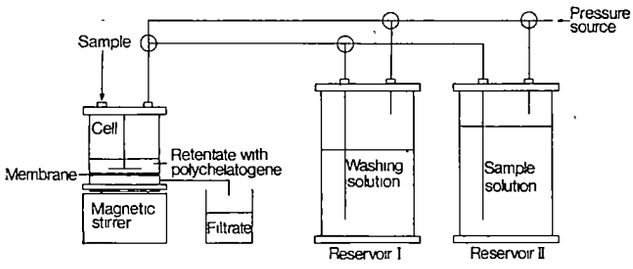

Fig. 1 The principle of metal separation with polychelatogens (from Chemische Fabrik Heyl) using membrane filtration. The sample solution is placed into the cell which contains an aqueous solution of polychelatogen (polymer reagent with chelating or other complexing groups). By adding the washing solution from reservoir I separation of metals is achieved by the selective retention of some of them in the retentate and the washing out of the others in the filtrate. Preconcentration of metals can be performed by passing the sample solution from reservoir II to the cell. The cell solution is then washed with the liquid from reservoir I.

The ultrafiltration cell is fitted with membranes, which retain molecules of molecular mass fractions greater than 10,000 (Berghof BM 10 or Amicon PM 10). Poly(ethyleneimine), poly(ethyleneimine-diacetic acid), poly(vinylpyrrolidone-*co*-vinylaminobutyric acid), poly(ethyleneimine-methylthiourea), and poly(acrylic acid-*co*-allylthiourea) act as polychelatogens in the cell as 1% aqueous solutions[3]. The average molecular mass of the polymer reagents is in the range 30,000–400,000 g mol^{-1} (ref. 3). Capacity studies of the polychelatogens have been reported previously[3]. The unfunctionalized poly(ethyleneimine), for example, binds 0.6–2.4 mmol metal per g polymer depending on the *p*H.

The initial concentration of metals in the cell solution (40 ml) or in reservoir II varies from 0.1 to 10 p.p.m.; the *p*H of the cell and reservoir solutions are adjusted to the same value. The system is pressurized (300 kPa), the cell solution stirred for 5 min and then washed with the reservoir fluid at a flow rate of 4–6 ml min^{-1}. The metal contents of filtrate fractions and cell solution are analysed by atomic absorption spectrometry. Other analytical methods in solution can be used, in principle, for metal analysis of the retentate; electroanalysis is also applicable[4].

The filtrate analysis data are used as the basis of the elution diagrams (Fig. 2) which show the metal concentration in the filtrate as a function of filtrate volume. If no metal can be detected in any filtrate fraction, complete retention has been achieved. When there is no retention, elution curves are obtained which can be approximated by the dotted curve in Fig. 2*b*. That curve is described by the exponential function:

$$C_f = C_0 e^{-V_f/V_0}$$

where C_f denotes the concentration of metal in the filtrate, C_0 the initial metal concentration in the cell, V_f and V_0 are the volumes of filtrate.

We have investigated the retention and separation of several metals using different polychelatogens. Typical results are shown in Table 1 for Co, Ni, Zn, Cd and Cu. Metal retention showed

Table 1 Retention of metal ions by poly(ethyleneimine) in the homogeneous phase at different *p*H values

	Retention (%)						
*p*H	Co^{2+}	Ni^{2+}	Zn^{2+}	Cd^{2+}	Cu^{2+}	Mg^{2+}	Na^{+}
2.1	1.2	<0.1	1.0	<0.1	86.3	—	—

5.3	>99.0	>99.0	>99 0	>99.0	>99.0	<0.1	<0.1

Polymer concentration, 1%; initial metal concentration, 10 p.p.m.; filtrate volume was equal to 10 volumes of cell solution.

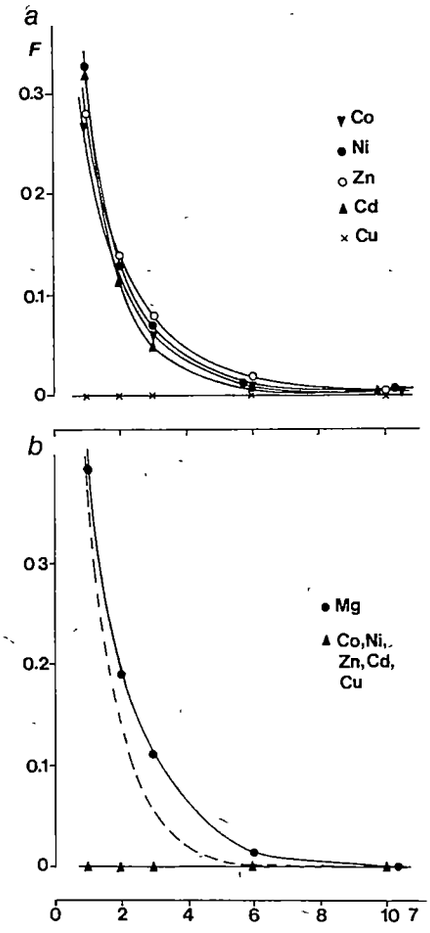

Fig. 2 Elution diagrams for some divalent metals separated by poly(ethyleneimine) using membrane filtration. Filtration quotient $F = C_f C_0^{-1}$ is plotted against the ratio $Z = V_f V_0^{-1}$ at *p*H 3.2 (*a*) and 5.3 (*b*); C_f and V_f, V_0 are concentration and volume of filtrate and cell respectively. Polymer concentration, 1%, $C_0 = 10$ p.p.m. Dotted curve, elution of an arbitrary metal which is not retained in the cell.

a strong dependence on *p*H, experiments were, therefore, performed at different *p*H values in the range 2–6. For example, >80% Cu was retained at *p*H 2.1 with $V_f = 10\ V_0$ (Table 1). Complete retention of Cu was achieved at *p*H 3.2, whereas the other four metals were washed out in the filtrate (Fig. 2*a*, Table 1).

The elution profiles of the metals Ni, Zn, Cd and Co are similar to the theoretical curve in Fig. 2*b*. At higher *p*H values, these metals are retained completely by poly(ethyleneimine); thus, they can be separated from other elements not bound to the polymer. For example, Mg and Na ions, which do not form stable complexes with this polymer, are washed out even at *p*H 5.3 (Table 1).

Other polychelatogens with different functional groups have proved to be effective for metal retention using membrane filtration. Poly(ethyleneimine-diacetic acid) can retain 90% Cu at *p*H 2.2 and >99% at *p*H 5. At this *p*H value, Cu is also complexed effectively by the *N*-methylthiourea derivative of poly(ethyleneimine). Moreover, this reagent allows the quantitative retention of Cd and Hg. Using the copolymer of acrylic acid and *N*-allylthiourea, Hg is even retained at *p*H 1.9. Poly(vinylpyrrolidone-*co*-vinylaminobutyric acid) showed a lower retention tendency than do the other polychelatogens studied.

To apply this procedure to the analysis of very diluted samples it is important to be able to preconcentrate the elements to be determined. The LCP technique allows preconcentration by using two reservoirs as depicted in Fig. 1. To demonstrate this, a model fluid containing metal ions and 3% of NaCl (concentration in seawater) was passed from reservoir II to the cell. The

volume of the sample fluid was 10 times higher than that of the cell solution.

After 10-fold preconcentration, the cell solution was washed with distilled water from reservoir I. At a 10-fold volume of filtrate referred to the cell fluid >98% of Hg, Cd, and Cu were retained by poly(ethyleneimine-methylthiourea), whereas poly(ethyleneimine) retained 75–95% of Cu, Ni, Zn, Cd and Cu. Note that the concentration of Na in the cell was as low as 3–5 p.p.m. after the washing. This means that the Na concentration decreased by 10^4 times and that a factor of 10^5 (relative preconcentration factor) for the metals retained is achieved when taking into account the first preconcentration step (absolute preconcentration). Another absolute preconcentration step (up to one order) can be applied by reduction of the cell solution volume using conventional ultrafiltration. In addition, it is an advantage for the analysis that the sample can be handled in the homogeneous phase

In conclusion, these polymeric reagents in combination with membrane filtration allow the enrichment and separation of trace elements in the presence of comparable and large excess quantities of sample constituents which could interfere with subsequent analysis.

We thank the Deutsche Forschungsgemeinschaft for financial support.

Evidence for an increase in cosmogenic ^{10}Be during a geomagnetic reversal

G. M. Raisbeck, F. Yiou & D. Bourles

Laboratoire René Bernas, 91406 Orsay, France

D. V. Kent

Lamont-Doherty Geological Observatory, Palisades, New York 10964, USA

Reversals in the geomagnetic field, which occur every few hundred thousand years, represent a dramatic change in the Earth's environment. Although there is no satisfactory theory for such reversals, it is generally accepted that the dipole field intensity decreases to <20% of its 'normal' value for a few thousand years during the change in direction[1]. Because the galactic and solar cosmic rays which impinge on the Earth's atmosphere are charged, a significant fraction (about half) of them are deflected by the geomagnetic field[2]. At the time of a reversal, this magnetic shielding is greatly reduced, and it has been suggested that the increased flux of high-energy particles could have effects on evolutionary[3] or climatic[4] processes. For example, the statistically significant coincidence in levels of some marine faunal extinctions and reversal boundaries in ocean sediments[5] could be caused, directly or indirectly, by the decreased geomagnetic intensity during the reversal. We report here evidence in marine sediments for an increase in cosmogenic ^{10}Be production in the Earth's atmosphere during the Brunhes–Matuyama reversal 730,000 yr ago. In addition to confirming an increase in cosmogenic isotope production, the results provide information on the magnitude and duration of the geomagnetic intensity decrease during such an event, and the depth at which remanent magnetism is acquired in marine sediments.

In previous work, we found no significant evidence for increased ^{10}Be (half-life 1.5 Myr) at a reversal boundary[6]. Among the explanations we gave for this negative result was that the sedimentation rate of the core studied (1.13 cm kyr^{-1}) was not high enough to retain a significant signal. We have thus looked at a core having a sedimentation rate of ~2.5 cm kyr^{-1}. This core, V16-58, was taken at 46°30′ S, 31°16′ E at a depth of 4,731 m. The material near the reversal zone is mostly diatomaceous lutite with thin interspersed layers of calcareous ooze[7]. The identification of the reversal level at ~1,129 cm as the Brunhes–Matuyama boundary, and the estimation of the sedimentation rate at this level are based on the biostratigraphy of Hays[7], with more recent studies putting the 425,000-yr extinction level of the radiolarian *Stylatractus universus*[8] at 420 cm (J. Morley, personal communication). The top part of the core has apparently suffered from a reduced sedimentation rate, hiatus or erosion.

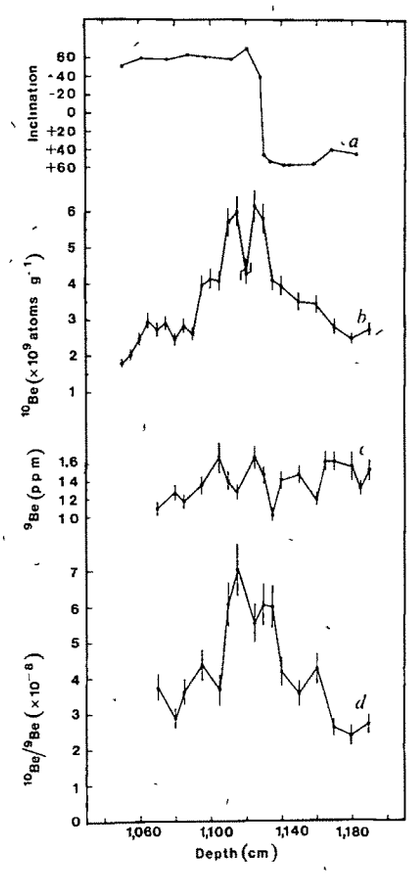

Fig. 1 *a*, Magnetic inclination; *b*, ^{10}Be concentration; *c*, ^{9}Be concentration; *d*, ^{10}Be/^{9}Be ratio as a function of depth in core V16-58.

Initial magnetic measurements, indicating a reversal level at ~1,129 cm, as shown in Fig. 1, were carried out using procedures described in ref. 9. After the ^{10}Be results became available, the core was resampled and the position of the reversal confirmed. A more detailed palaeomagnetic investigation around the reversal level is now in progress.

For the ^{10}Be measurements, samples of 0.3–1 g were dissolved in the presence of 0.5 mg of ^{9}Be carrier, and chemical purification carried out as described earlier[6]. The ^{10}Be measurements were made on a Tandetron accelerator mass spectrometer facility, using the procedure described in ref. 10. Several thousand ^{10}Be events were recorded for each sample, and the estimated uncertainties are due to instrumental variations, as deduced from replicate measurements of standards[10]. The results are shown in Fig. 1. The low value at 1,120 cm during the initial series of measurements was so surprising that we processed and measured a second portion of the same sample. The good agreement between the two results both confirms the low value for this sample, and gives us added confidence that our assigned uncertainties are realistic.

As can be seen in Fig. 1, the ^{10}Be concentration increases by a factor of ~2 for samples near the reversal level. Before

ascribing this to a production increase, it is useful to consider other possible factors which could effect a change in ^{10}Be concentrations. For example, a change in the biological productivity, possibly associated with the reversal, could give rise to a variable biogenic component (opal or calcium carbonate) in the sediments; this would probably give a variable dilution of the ^{10}Be. Another possibility is that some change in environmental conditions might lead to an 'enrichment' of beryllium compared with other components in the sediment. To examine these alternatives, we have measured the stable isotope ^{9}Be over the same interval as the ^{10}Be. The ^{9}Be was measured by flameless atomic absorption spectrometry. Uncertainties in the ^{9}Be concentrations are estimated from the reproducibility of the measurements (in all cases except one, the results are the average of at least two determinations). The decision to measure ^{9}Be was made after the completion of the ^{10}Be measurements. Unfortunately, this meant we did not have material remaining for some of the levels, including the critical minimum at 1,120 cm, in which ^{10}Be had been determined.

Although there are variations in the measured ^{9}Be, these do not parallel those of ^{10}Be. In fact, the ^{10}Be/^{9}Be ratio, also given in Fig. 1, shows a peak similar to ^{10}Be alone. Unfortunately, this normalization may not be completely satisfactory. Although the oceanic geochemistry of ^{9}Be is still poorly known, we believe[11,12], contrary to Measures and Edmond[13,14], that a significant fraction of ^{9}Be may be deposited in marine sediments without coming to equilibrium with ^{10}Be. In such a case, the ^{9}Be would be an imperfect tracer for ^{10}Be, although it still should compensate for a variable biogenic component.

While the ^{10}Be/^{9}Be evidence strongly supports the interpretation of the observed increase of ^{10}Be concentration as being due to increased production, it is not necessarily a better monitor of ^{10}Be production variations. However, because of the similarity in the two curves (except for the minimum at 1,120 cm), the conclusions that follow are relatively insensitive to which one is used.

We also note that both ^{10}Be concentration and ^{10}Be/^{9}Be are of potential interest as dating tools[11,15]. The strong variation in these parameters observed here demonstrates that caution must be exercised when dating by such procedures near reversal levels. In a preliminary study, Ku *et al.*[15] have also observed a high ^{10}Be concentration in a single sample near the Brunhes–Matuyama reversal level. However, they also found an abnormally low concentration in a sample nearby, so the origin of their variations is not clear.

The ^{10}Be (or ^{10}Be/^{9}Be) signal is not expected to reflect directly the geomagnetic palaeointensity profile for two reasons. First, the effect of the magnetic field on production rate is a function of geomagnetic latitude[2]. The degree to which mixing in the atmosphere and the ocean average out this variation is not yet established. However, the mid-latitude location of V16-58, in a region of significant input of stratospheric aerosols, means that its sediment probably should reflect a reasonably 'average' production effect. Second, once the ^{10}Be is incorporated in the sediment, it is subject to mixing processes by benthic organisms. To illustrate the potential effect of this bioturbation, we adopt a model[16] in which the sediment is assumed to be completely homogenized over a given depth, called the mixed layer, with no mixing below this depth. A more sophisticated model has been proposed which treats the mixing process explicitly by diffusion[17]. However, we do not have independent information on the appropriate diffusion constant for this core. For diffusion constants >100 cm^2 kyr^{-1} the uniform mixing assumption is a good approximation to the diffusion model.

Adopting a mixed-layer thickness of 10 cm, we calculated output profiles for several different assumed input profiles. Figure 2 shows an example of one of these which fits the observed ^{10}Be profile reasonably well. As can be seen in Fig. 2, the bioturbation has three effects. It attenuates the maximum increase in production rate; it tends to smooth out rapid variations; and it moves the ^{10}Be levels down by approximately the assumed mixing depth.

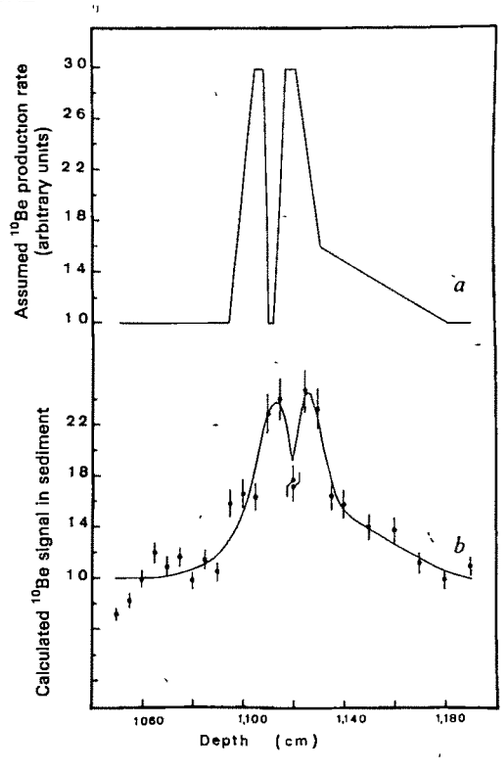

Fig. 2 *a*, Assumed ^{10}Be production rate profile; *b*, solid curve is calculated signal in sediment, using the bioturbation model described in the text, with a mixing depth of 10 cm. Points are experimental data from Fig. 1.

The input profile of Fig. 2 is, of course, not unique, and others which fit the experimental data equally well, or better, could be found. However, we do have some constraints. First, the maximum increase in production during the reversal cannot be significantly larger than the factor of 3 we have chosen, which corresponds essentially to a zero-intensity magnetic field[2]. Second, the total area under the input and observed curves must be the same. Thus, the input function in Fig. 2 should represent at least the major features of the actual production curve. In particular, the mean duration for the production increase (and thus magnetic intensity decrease) should be approximately correct. As can be seen in Fig. 1, the interval of increased ^{10}Be is significantly longer than the time taken for the reversal of inclination. Such a result is consistent with other evidence which suggests that the geomagnetic field intensity is low before and after the change in inclination[1,18]. From Fig. 1, the interval of increased production is ~30–60 cm, depending on what level of increase is chosen. Assuming a sedimentation rate of 2.5 cm kyr^{-1}, this interval corresponds to ~12,000–24,000 yr; this is similar to the time interval for the decreased magnetic field at another reversal, as estimated in ref. 18.

As can be seen in Fig. 2, the minimum at 1,120 cm implies a very significant decrease in production. However, the magnitude and duration of this decrease are obviously very strongly dependent on the parameters of the bioturbation model used. Thus, even if this decrease is due to an increased field intensity, the quantitative nature of the required change remains uncertain. It is interesting, however, that other authors have also found evidence for high intensities midway through reversals[19,20]. More definite conclusions along these lines will necessitate more detailed ^{10}Be and palaeomagnetic profiles, comparison between several cores and more reliable bioturbation modelling. With regard to the latter, although the bioturbation depth used here is fairly typical[16,17], we wonder whether it can be reconciled with the rather abrupt variations seen in ^{10}Be, ^{9}Be and calcium carbonate[7], over intervals as small as 5 cm. Piseas has recently made the same point regarding oxygen-isotope profiles in other cores[21]. Reduced bioturbation would mean that the actual ^{10}Be

production profile would approach more closely the observed ^{10}Be profile.

As we have discussed earlier[6], the location of the ^{10}Be peak compared with the reversal level can also provide information on the depth at which remanent magnetization is acquired in marine cores. In the present case, it can be observed that the midpoint in the ^{10}Be peak is ~10 cm above the change in magnetic inclination (or ~15 cm if we use the input profile of Fig. 2). Neglecting the residence time of ^{10}Be in the ocean[22], and assuming that the ^{10}Be midpoint corresponds to the change in direction, this would indicate that the magnetic remanence was 'locked in' at a depth of ~10–15 cm in the sediment (or slightly more, allowing for later compaction). This is consistent with the idea that the magnetic remanence is acquired at the base of the bioturbation zone.

We have presented the first direct evidence for increased cosmic ray radiation in the Earth's atmosphere during a geomagnetic reversal. Making some reasonable assumptions, the data also allow one to deduce significant information on the magnitude and duration of the magnetic intensity decrease during a reversal, and the depth at which detrital magnetic remanence is acquired in a marine sediment. It will be interesting to pursue this type of study at other reversal boundaries to determine whether there are significant differences in their intensity profiles, and, if so, whether they could be correlated with other features such as the severity of faunal extinctions. This work also demonstrates that ^{10}Be should be a potentially powerful tool for testing the global nature of various geomagnetic 'excursions' that have been observed during the Brunhes epoch[23].

We thank D. Deboffle and J. Lestringuez for technical assistance, and J. Hays for originally suggesting core V16-58 for this work. Palaeomagnetic measurements were supported by NSF grant OCE84-00805; core curation and sampling at LDGO is supported by grants OCE82-16061 and OCE81-22083.

Re-dating the English art-historical tree-ring chronologies

M. G. L. Baillie*, J. Hillam†, K. R. Briffa‡ & D. M. Brown*

* Palaeoecology Centre, Queen's University, Belfast BT7 1NN, UK
† Department of Archaeology and Prehistory, University of Sheffield, Sheffield S10 2TN, UK
‡ Climatic Research Unit, University of East Anglia, Norwich NR4 7TJ, UK

Precisely dated oak (*Quercus petraea* Liebl. and *Q. robur* L. and their hybrids) tree-ring chronologies that show consistent cross-dating from Germany to England to Ireland[1,2] have been labelled Type H[3]. In contrast, there have been difficulties in specifying the exact date ranges of some oak chronologies (termed Type A)[3] constructed from art-historical timbers in England[4,5] and the Netherlands[6,7]. It has been asserted that the oak planks and boards used in the English art-historical chronologies derived from England and Flanders[3,8]. The failure of these chronologies to date uniquely against Type H chronologies from the British Isles has led to suggestions that the timbers were imports, probably from the Baltic area[1,9], views supported by historical evidence[10,11]. It has also been suggested that the dating procedure used for these chronologies has an element of circularity which could result in an erroneous placement of the chronologies going undetected[12]. Evidence is presented here which indicates that the art-historical chronologies have been incorrectly dated, that they represent imports into England and Flanders and that failure to take account of exotic origins has led to the use of unsuitable estimates for missing sapwood.

In 1975, information on cold winters in the fifteenth century was derived from a section of art-historical oak tree-ring chronology, MC18, dated[13] to AD 1234–1550. This section of chronology had originally been designated[4] to the years 1230–1546 and subsequently reference chronologies related to MC18 (designated Refs1–4) were returned to this same '1546' dating[3,5,14]. These chronologies, all >270 yr in length, form an internally consistent group covering the period from the early twelfth to the early seventeenth centuries. At other times Refs1–4 have been moved 1-yr-back, equivalent to a '1545' dating[8,15,16] of MC18. The possibility of a circular argument in the dating of these art-historical chronologies has recently been discussed in an article which also gives documentary evidence for importation of oak planks and boards into England and Flanders from the Baltic during the later Middle Ages[12]. Since that publication, three new pieces of evidence relevant to these Type A chronologies have become available.

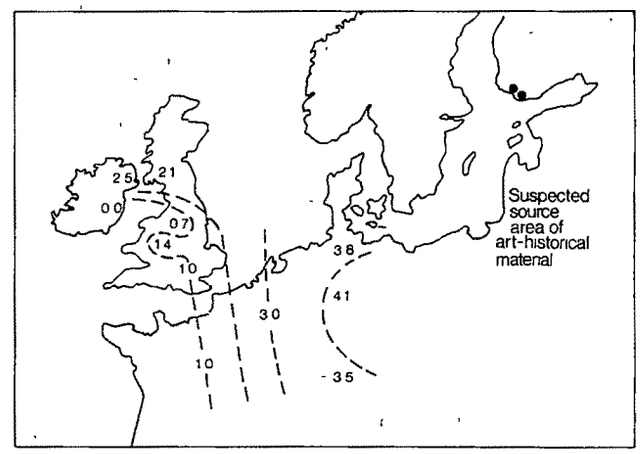

Fig. 1 Mean '*t*' values for the nine art-historical chronologies compared with 11 available Type H chronologies as in Table 1*c*, with the Type A chronologies in the 4-yr-forward or '1550' position. ●, The source of the Finnish oak sapwood values.

First, one of us (J.H.) acquired some medieval timbers from excavations at Ipswich. The mean ring pattern of three timbers was found to span the years AD 1128–1293 by cross-dating against the established, and absolutely dated, German Type H (after Huber[3]) chronologies of Eckstein (personal communication) and Delorme[17]. The correlation values between the Ipswich mean ring-pattern and these two chronologies, obtained using the Belfast CROS program[18], were '*t*' = 7.2 and '*t*' = 4.1 respectively for overlaps of 166 yr (normally '*t*' values >3.5 in association with overlaps of more than 100 yr are regarded as significant indicators of a likely tree-ring match). No significant

correlations could be found with any of the existing British Isles Type H oak chronologies. However, when this Ipswich ring-pattern was compared with the Ref4 Type A chronology[5], a significant correlation value ('t' = 5.3, overlap 166 yr) was obtained with Ref4 ending not in AD 1399 as published, but in 1403, that is, equivalent to the 4-yr-forward or '1550' dating used in 1975[13].

Almost immediately an exactly analogous situation was found by another one of us (M.B.). The mean ring pattern of two boards from a seventeenth-century painting of St Matthew was dated to the years AD 1326–1625 against the Type H German chronologies of Hollstein[19] and Becker[20] with 't' = 10.6 and 11.3 for overlaps of 300 yr in each case. When compared with the published Type A chronologies, significant correlation values were obtained at the '1550' position ('t' = 5.1 for Ref3, 't' = 4.6 for Ref2 with overlaps of 270 and 246 yr respectively).

Following these results, we re-examined the dating of the Type A chronologies. Most workers outside the art-historical field had assumed that more persuasive evidence must exist for the '1545' and '1546' chronology placements than for the '1550' placement and that all of the possibilities would have been explored by the art-historical workers. Table 1 shows the correlations obtained for all of the available Type A chronologies, namely MC18[4], Refs1–4[5] and variants NewRef1, NewRef2/3 and Ref2/3/5 (J. M. Fletcher, personal communication), when compared with the published Type H chronologies from Göttingen[17], Hamburg (ref. 21 and D. Eckstein, personal communication), South Germany[20], West Germany[19], Belfast[22], Scotland[23], Giertz[24], northern France (J. R. Pilcher, personal communication), English MC10 (J. M. Fletcher, personal communication), Sheffield[25] and Dublin[26] at the '1545', '1546' and '1550' positions.

Consistent with the Type A dating suggested by the Ipswich and St Matthew examples above, there is strong correlation between the Type A chronologies and the principal published German Type H chronologies at the '1550' position. There is much less agreement with chronologies from the British Isles at this position. There is no consistent agreement with the Type A chronologies placed at the '1545' or '1546' positions. Figure 1 shows how, at the '1550' placement, the mean correlation values for the Type A chronologies increase as they are compared with more easterly chronologies. The values are not high enough to support an origin for the art-historical timbers within Germany (see, for example, the correlations obtained for the St Matthew boards) but they clearly indicate a likely origin to the east of the German chronologies. This would be consistent with an eastern Baltic origin which has been suggested on historical grounds[12].

But why has this level of consistent correlation (against published chronologies) which indicates a '1550' dating been ignored and why was this same dating, used[13] in 1975, overridden? It is referred to as being "discarded on account of poor visual agreement"[5] and elsewhere the temporary use of the '1550' position is accounted for by a "4-yr periodicity in our oak chronology"[27].

In a '1550' re-dating of the art-historical chronologies, the time left between the last heartwood rings of surviving ring

Table 1 Correlation values obtained using the Belfast CROS program[18] for comparisons of nine art-historical chronology variants with precisely dated Type H chronologies

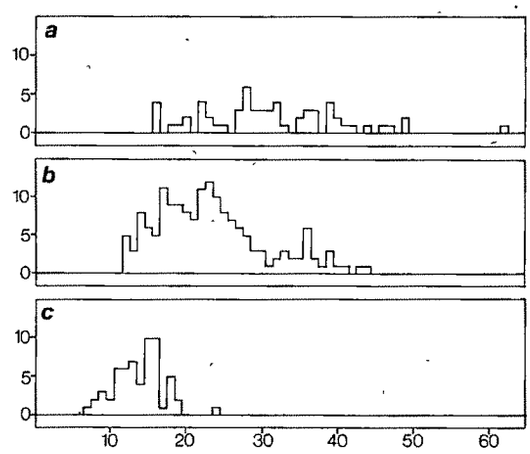

Fig. 2 Frequency of sapwood numbers in oaks from: *a*, England[12,28]; *b*, West Germany[29]; *c*, Finland.

patterns and the use dates for 'known age' paintings is shortened by 4 yr. In one of the examples used by Fletcher *et al.*[4] (Thomas, second Baron Wentworth, painted 1568), the '1550' chronology placement leaves only 20 yr between its last heartwood ring and 1568. This period has to account for both sapwood and seasoning factors. In the case of the First-Viscount-Montague panel (painted 1569) only 15 yr are left to account for possible missing heartwood, missing sapwood and seasoning. Such intervals would be unacceptably short for English panels given the numbers of sapwood rings observed on modern English oaks[12,28] and it may have been the erroneous belief in an English origin for the panels which made the possible '1550' dating unacceptable.

If our revised dating is accepted, it suggests that the number of oak sapwood rings in the area from which the panels derived must have been less than the numbers normally accepted in England. Sapwood on mature oaks tends to be shorter in Western Germany[29] and substantially shorter for Roman (mean 18, range 11–27) and Dark Age (mean 17, range 11–21) oaks in South Germany[20,30] We now have evidence for oaks from the eastern Baltic as the result of field work by members of the University of East Anglia Climatic Research Unit in 1984. The samples are 60 cores from 49 trees from two sites in southwestern Finland—Ruissalo and Solbole (all trees were *Q. robur*). The mean number of sapwood rings is 13.9 with a standard deviation of 3.2 and values range from 7 to 24. All trees were >120 yr in age. The mean number of sapwood rings from the Finnish sites is significantly smaller than the English sapwood values at the $P < 0.0001$ level (Fig. 2).

These results suggest that: (1) an eastern Baltic origin for the art-historical chronologies as suggested on historical grounds; (2) a movement of the art-historical chronologies forward to a '1550' placement; and (3) a very short sapwood interval are all compatible. When vindicated by subsequent work on Polish or Lithuanian timbers, these results make it inevitable that all of the art-historical datings derived using the '1545' or '1546' chronology placements, and the specifically tailored sapwood estimates favoured by some workers[15,31], will have to be revised. If the German art-historical dendrochronologists favour a '1548' chronology placement for their equivalent Netherlands II chronology[3], then all their dates will move forward in time by 2 yr. However, their estimated felling dates may have to be additionally revised in the light of the very short Baltic sapwood observations above.

We thank Dr Martin Munro for discussion. Field work in Finland was funded by EEC grant CL.111.UK(H).

Patterns of mortality and age at first reproduction in natural populations of mammals

Paul H. Harvey*

Department of Biology, Princeton University, Princeton, New Jersey 08544, USA

Richard M. Zammuto

Kananaskis Centre for Environmental Research, University of Calgary, Seebe, Alberta, Canada T0L 1X0

There is great variation in the age at which females of different mammalian species first breed. Recent comparative analyses have focused on the relationship between age at first reproduction and body size[1–9], but differences in patterns of mortality experienced by natural populations are expected to have major effects on selection for age at first reproduction[10–14]. Here we show that the age at which females first reproduce is strongly correlated with expectation of life at birth, after the effects of body size have been removed, within and among species of mammals living in natural populations.

Some shrews give birth when they are only 7 weeks old[15], whereas female African elephants produce their first offspring at an age of some 15 years[16]; such differences in age at first reproduction are highly correlated with the species' differences in body size[1,2,8,9], suggesting that the time required to grow to adult size determines the age at which mammals become sexually mature[2,4]. Consistent with this idea, the timing of many physiological and reproductive processes (for example, cardiac cycle time and maximum recorded lifespan) scale in similar ways with body size, approximately to the 0.25 power[4,8].

However, body size might be a confounding factor in the sense that it influences one variable which in turn influences some other variable; both variables would then be correlated with body size. For example, species with high rates of mortality in the wild might be selected to mature earlier than those which are long-lived, but rates of mortality might be influenced by body size (larger species can defend themselves against predators more effectively and they can survive for longer periods without food[6]). Data are now available on mortality patterns,

* Present address Department of Zoology, University of Oxford, South Parks Road, Oxford OX1 3PS, UK

body sizes and age at first reproduction of females for 29 mammal species (representing 25 genera and 6 orders) from natural populations with stable age distributions[17]. The species range in weight from 20 g to 4,000 kg. In addition, equivalent data are available from six populations of a further species, the Columbian ground squirrel, *Spermophilus columbianus*[18,19]. These data can be used to test the hypothesis that differences in patterns of mortality are correlated with the ages of the females at first reproduction.

Six of the species in the sample belonged to two genera (*Spermophilus* and *Peromyscus*) and, to reduce taxonomic bias, analyses were performed at the generic level (that is, on the averages of logarithmically transformed congeneric species' values). All variables were logarithmically transformed before analysis. As a summary measure of mortality, we have used Millar and Zammuto's[17] estimates of mean life expectancy at birth in years (a comparison of the use of this versus other measures will be presented elsewhere). Genera with low mortality have a high expectation of life at birth. The correlation between age of females at first reproduction and life expectancy at birth is high and positive ($r=0.976$, $n=25$, $P<0.001$). This correlation, however, might result from independent correlations of each variable with body size, but this seems not to be the case since the two variables are more highly correlated with each other ($r=0.976$) than either is with body size ($r=0.894$ and 0.873 respectively, $n=25$ in both cases), and they remain highly correlated after the effects of body size have been removed by partial correlation ($r=0.892$, $n=25$, $P<0.001$). The latter relationship means that mammals with an unexpectedly long lifespan (relative to body size) start reproducing relatively late (again relative to body size). The relationship is demonstrated graphically in Fig. 1—note the taxonomic spread. Genera from each of the two best-represented orders, the Artiodactyla and the Rodentia, cover most of the ranges of relative age at first reproduction and relative life expectancy. The removal of size effects is also evident: values for squirrels lie near that for the elephant, and the value for mice near that for the warthog. A positive partial correlation between age at first reproduction and life expectancy at birth, with the effects of body size removed, also holds among populations of the Columbian ground squirrel ($r=0.874$, $n=6$, $P=0.05$).

Probably as a consequence of constraints imposed by seasonality, seven of the genera in the cross-species sample mature as 1-yr-olds (ranging in weight from the 0.1-kg *Tamias* to the 7.5-kg *Lynx*). When the analysis is repeated without these genera, the correlation between age at first reproduction and life expectancy (with body size effects removed) remains high and significant ($r=0.836$, $n=17$, $P<0.001$). Of course, differences in body size may still influence age at first reproduction. Elephants could not mature and produce offspring in the few weeks that it takes shrews or mice to mature and, indeed, the partial correlation between age at first reproduction and body size with the effects of life expectancy removed is positive, though barely significant ($r=0.390$, $n=25$, $P<0.1$).

To test for the possibility that gestation length, litter size, neonatal weight or litter weight was ultimately responsible for the correlation between age at first reproduction and life expectancy, data on these variables for the species in the sample were extracted from the literature[20–24], and the effect of each new variable was removed by partial correlation. With the effect of each variable removed, in no instance did the correlation between age at first reproduction and life expectancy fall below 0.9.

The positive relationship between age at first reproduction and expectation of life at birth, after removal of the effects of body size, calls for an explanation in terms of the costs and benefits of reproduction at different ages. Perhaps the most straightforward interpretation is that each bout of reproduction reduces subsequent reproductive success (either by further increasing mortality or by decreasing fecundity), and that older mothers produce larger litters (and/or more viable offspring) than do younger mothers[19]. As life expectancy at birth decreases

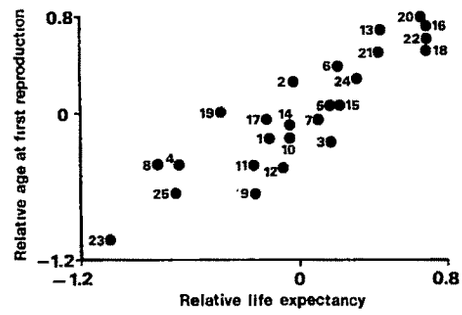

Fig. 1 Relative age at first reproduction plotted against relative life expectancy at birth for natural populations of mammals. Relative values refer to deviations from logarithmic regression lines of age at females' first breeding, or expectation of life at birth, on adult female body size. Numbers refer to different mammalian genera. Artiodactyla: 1, *Syncerus* (buffalo); 2, *Hippopotamus*; 3, *Aepyceros* (impala); 4, *Sus* (pig); 5, *Cervus* (deer); 6, *Ovis* (sheep); 7, *Hemitragus* (tahr); 8, *Phacochoerus* (warthog); 9, *Kobus* (kob); 10, *Connochaetes* (gnu). Carnivora: 11, *Taxidea* (American badger); 12, *Lynx*; 13, *Lutra* (river otter); 14, *Mephitis* (skunk). Lagomorpha: 15, *Sylvilagus* (cottontail rabbit); 16, *Ochotona* (pika). Perissodactyla: 17, *Equus* (zebra). Proboscidea: 18, *Loxodonta* (African elephant). Rodentia: 19, *Castor* (beaver); 20, *Tamias* (chipmunk); 21, *Spermophilus* (ground squirrel); 22, *Sciurus* (grey squirrel); 23, *Clethrionomys* (vole); 24, *Tamiasciurus* (red squirrel); 25, *Peromyscus* (mouse).

under such circumstances, selection will favour maturation at earlier ages. (This interpretation may also be consistent with an apparently similar relationship, pointed out by Lack[25], between age at first reproduction and patterns of mortality among families of birds.) At a more proximate level, nutrition levels may influence the correlations. High nutrition levels can result in early maturation[26,27] and decreased lifespan[28] within and among mammal species, for example, Columbian ground squirrel populations mature earlier and have shorter life expectancies when natural food resources are more abundant[18,19].

We thank J. Levinton, R. D. Martin, T. H. Clutton-Brock, J. Seger, J. Gittleman and R. M. May for advice and discussion, and the Toronto Zoo for data on the neonatal weight of *Hemitragus*. P.H.H. thanks the members of the Department of Biology at Princeton University for discussions, and for their financial support through Princeton's 3W training grant scheme.

An antiemetic is antidotal to the satiety effects of cholecystokinin

Beth O. Moore & J. A. Deutsch

Department of Psychology, University of California, San Diego, San Diego, California 92093, USA

Although cholecystokinin (CCK) has been proposed as a satiety agent[1–4], this property has been disputed by some who claim that the compound exerts its 'satiety' effects by inducing aversion[5–7]. We considered that if CCK-induced reductions in food intake occur through the mechanism of normal satiety, CCK-induced satiety and normal satiety should respond in the same way to a pharmacological challenge. We demonstrate here that the administration of an antiemetic to rats significantly attenuates the food intake reduction caused by exogenously administered CCK but does not increase normal consumption. The effects of endogenous CCK are therefore quite different from those of exogenous CCK, making any previous study equating exogenous CCK effects with natural satiety problematic.

Ninety-eight male Wistar rats (300–450 g) were housed and tested in individual wire mesh cages and maintained on a 12-h light/dark cycle. Tap water was available *ad libitum* and a maintenance diet of Purina rat chow was available for 2 h each day, beginning at 17.00 h. The rats were trained to drink a 1:1 Mazola corn oil/water solution emulsified with 1% lecithin (a diet expected to stimulate endogenous CCK release[8,9]) for 30 min each day after a 17-h period of food deprivation and were habituated to receive intraperitoneal (i.p.) injections of physiological saline. Rats were then assigned to one of four conditions matched by mean intake and standard deviation—saline–saline (S–S), antiemetic–saline (A–S), antiemetic–CCK (A–CCK) and saline–CCK (S–CCK). Each rat received two injections and was then given the emulsion to drink for the usual 30 min. The first drug for each group was given 30 min before the rat received his oil and the second drug immediately before oil presentation. The saline-treated rats received 0.9% saline solution (1 ml per kg, i.p.) and the antiemetic-treated rats received trimethobenzamide (5 mg ml^{-1} per kg, i.p.). (This drug and dose was used by Coil *et al.*[10] to show that antiemetics could be used to attenuate LiCl-induced aversions. Trimethobenzamide is an antiemetic which acts specifically on the chemoreceptor trigger zone and has been shown to be useful in alleviating nausea in humans.) Cholecystokinin octapeptide (Sincalide; Squibb) was administered i.p. at 5, 10, 20 or 40 Ivy dog units (IDU) per ml per kg.

The different CCK doses were tested in three successive sets of new naive rats, the initial oil and saline injection training being the same for each set. In the first set, after oil intake stabilization, 28 rats were divided equally into the four conditions, with the CCK rats receiving a dose of 20 IDU per ml per kg i.p.; in the second set, another 28 rats received CCK at 10 IDU per ml per kg, and in the final set, the extreme CCK doses (5 and 40 IDU) were given to one S–S group and one A–S group ($n = 42$). (Because the S–S and A–S controls were so stable in the previous two sets, only one S–S and one A–S control (seven rats in each) was run for each of the two CCK doses.)

One score was obtained for each rat by comparing the percentage consumpion on the experimental day with the mean consumption for the previous 3 days. Per cent mean intake scores were used rather than absolute intake scores, to minimize any potential differences in average drinking between the three sets of this experiment. The day of the experimental manipulation and the group of animals chosen for each set had no significant effect on the results. For the two control conditions (S–S and A–S), there was no significant difference in intake from one run to the next. An analysis of variance showed that the per cent mean intake between sets was not significantly different ($F = 0.49$, d.f. $= 2, 36$, $P > 0.05$). Furthermore, individual t-tests between an S–S and any other S–S condition and t-tests between an A–S and any other A–S condition showed no significant differences.

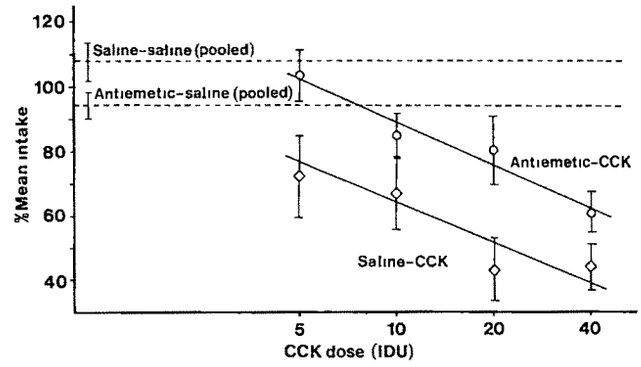

Fig. 1 Per cent mean intake (s.e.m.) of oil emulsion under four conditions of drug injections: saline–saline, antiemetic–saline, antiemetic–CCK and saline–CCK. The control S–S scores and the control A–S scores are pooled and are represented as dotted lines.

The pooled S–S group (from all three sets) consumed 108.1% of its normal amount on the experimental day (Fig. 1) and the pooled A–S group consumed 94.5% of its normal amount. Whereas neither the S–S group nor the A–S group showed significantly different consumption from normal (respectively $t = 1.30$, $n = 21$, $P > 0.05$ and $t = 1.30$, $n = 21$, $P > 0.05$), the A–S group showed marginally lower consumption than the S–S group ($F = 3.21$, d.f. $= 1, 36$, $P < 0.05$, one-tailed only). The antiemetic therefore did not increase normal consumption and, if anything, slightly reduced it.

The antiemetic attenuated the effect of CCK, results with the A–CCK group being significantly different from those of the S–CCK group ($F = 14.7$, d.f. $= 1, 48$, $P < 0.001$). The antiemetic (A–CCK) scores were higher than the saline (S–CCK) scores for all doses of CCK administered. Furthermore, whereas consumption in the S–CCK groups was always significantly different from their control (S–S) ($t = 4.90$, d.f. $= 12$, $P < 0.001$ for 40; $t = 4.01$, d.f. $= 12$, $P < 0.01$ for 20; $t = 2.84$, d.f. $= 12$, $P < 0.05$ for 10; $t = 2.59$, d.f. $= 12$, $P < 0.05$ for 5), that in the A–CCK groups was significantly different from their control (A–S) only for the highest CCK dose ($t = 2.67$, d.f. $= 12$, $P < 0.05$ for 40; $P > 0.05$ for 20, 10 and 5 IDU per ml per kg.

Because the antiemetic increased intake under CCK by about 26% for each dose of CCK used, if exogenous CCK were equivalent to natural satiety, normal intake with the antiemetic should have increased by 26% also. Instead, the antiemetic-treated rats consumed only 95% of their normal amount, rather than the expected 134%.

Clearly, exogenously administered CCK cannot be used as a model for natural satiety. Antiemetic administration increases eating after CCK injection, eliminating the supposed satiety effect of exogenous CCK. However, the antiemetic reduces or leaves unaffected normal eating when no CCK is given. The factors producing food intake reduction through CCK injection and the factors causing normal meal regulation therefore cannot be the same. Because the antiemetic is antidotal to CCK and because the antiemetic is not antidotal to normal satiety, it seems very likely that the factor causing food intake reductions after CCK administration is malaise and that malaise is not a factor producing normal satiety.

We thank Dr A. Ondetti, Squibb Institute for Medical Research, for his gift of CCK octapeptide, and Best Foods for their donation of Mazola corn oil.

Segregation of pathways leading from area V2 to areas V4 and V5 of macaque monkey visual cortex

S. Shipp & S. Zeki

Anatomy Department, University College London, Gower Street, London WC1E 6BT, UK

V5 and V4 are areas of macaque monkey prestriate visual cortex that are specialized for involvement in different aspects of visual perception, namely motion for V5 (refs 1–4) and colour vision, with other possible functions, for V4 (refs 2, 5–9). Thus, it is unlikely that they should be fed the same information for further processing, yet both receive a strong input from patches of the upper layers of V2 (refs 10, 11), the area immediately adjoining the primary visual cortex, V1. V2, however, seems to comprise functionally distinct subregions, which can be revealed by staining the tissue for the mitochondrial enzyme cytochrome oxidase[12–15]. Here we report that V4 and V5 are connected with separate cytochrome oxidase-defined subregions of V2, suggesting that cortical pathways dealing with motion and colour perception are segregated in their passage through V2, and reinforcing evidence for functional specialization in the visual cortex[16–18].

In primates, the primary visual cortex V1 (area 17 or striate cortex) receives most of the visual input to the cerebral cortex and sends parallel outputs to several of the visual areas[19] which, between them, comprise Brodmann's areas 18 and 19 of prestriate cortex. Because of this anatomical arrangement and the functional specialization in the prestriate areas[16,17], it was suggested that one function of V1 is to segregate different kinds of visual information relating to colour, form, motion and depth, and to distribute these to different prestriate areas for further processing[19]. Confirmation of this role of V1 has come from physiological studies in combination with cytochrome oxidase histochemistry. Tissue stained for this enzyme shows an array of 'blobs' in the upper layers of V1 in which are concentrated cells selective for wavelength but not orientation. In the more lightly staining 'interblob' regions, however, cells are normally not wavelength- but orientation-selective[15]. V2, the prestriate area bordering V1 (but occupying only part of area 18) receives a strong input from V1 (refs 20, 21) and, like it, contains several functional cell types[16,22] and projects to several other prestriate areas[23,24]. It, too, has a characteristic staining pattern for cytochrome oxidase, consisting of a series of stripes running orthogonal to the V1/V2 boundary[12–15]. These are best visualized in tangential sections through the flat mounted occipital operculum (Figs 1*c*, 2*a*) where in most cases the dense stripes are alternately thick and thin and are separated by lighter regions more uniform in size, the 'interstripes'. Two of these three sets of repetitive subregions receive specific projections from V1, the thin stripes from the blobs and the interstripes from the interblobs, but the specificity (if any) of the input to the thick stripes from V1 remains unknown[15].

Thus, the cytochrome oxidase-defined subregions of V1 and V2 are probably involved in segregated pathways of distinct functional characters and we sought to determine how the subregions of V2 project to the more uniformly specialized areas of prestriate cortex such as V5 and the V4 complex. These latter two areas differ profoundly in their functional characteristics: there is a total absence of wavelength-selective cells in V5, most cells being directionally selective[1–3,25], whereas V4 (which consists of at least two areas, each with probable subdivisions[6]) contains heavy concentrations of wavelength- and colour-sensitive cells but few that are selective for direction[5,8,19]. Thus, by relating the distributions of cells projecting to V4 or V5 with the pattern of cytochrome oxidase stripes, it might be possible to associate specific subregions of V2 with specific visual functions.

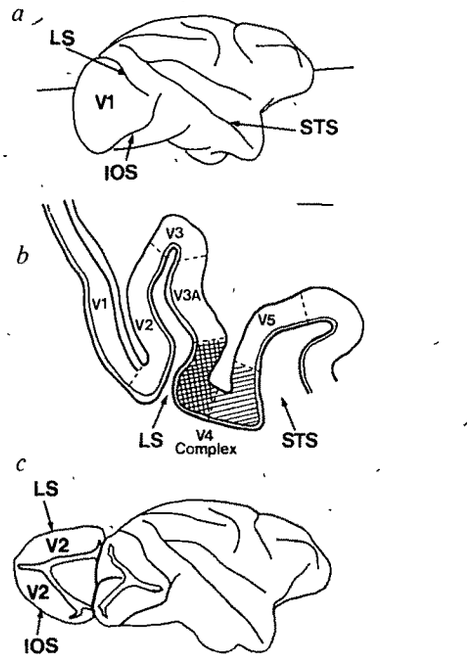

Fig. 1 Drawing of *a*, the surface of the left hemisphere of a macaque monkey brain, *b*, the lateral part of a horizontal section, taken at the level indicated in *a*, to show the locations of the three areas studied. The V4 complex (V4) consists of at least two areas with further subdivisions in each In this study, the injections were made in the posterior part of the V4 complex (cross-hatched) *c*, Illustration of how the occipital operculum is removed and showing the relation of V2 to V1. LS, lunate sulcus; STS, superior temporal sulcus; IOS, inferior occipital sulcus Scale bar, 2 mm.

Injections of wheat-germ agglutinin horseradish peroxidase (HRP) (0.1-0.3 μl of a 4% solution) were made into area V5 in three monkeys and is V4 in five monkeys. After 48-h survival, the animals were anaesthetized and perfused, following standard procedures, after which the brains were sectioned at 50 μm and pairs of adjacent sections stained for cytochrome oxidase[26] and reacted for HRP[27]. The cytochrome oxidase-stained sections were drawn at ×30 magnification under a drawing tube, with the boundaries of the cytochrome oxidase heavy zones and blood vessels marked. The adjacent HRP section, suitably magnified to compensate for its greater shrinkage, was superimposed according to the blood vessels and the positions of labelled cells and terminals added to the diagram. In this way, it was possible to determine the relation of the labelled cells to the cytochrome oxidase stripes in V2.

Where injections of HRP are made into V4 or V5, labelled cells and terminals in V2 are distributed in bands running orthogonal to the V1/V2 boundary and are very similar in disposition to the cytochrome oxidase stripes. The similarity is even more striking because, just as the cytochrome stripes show periodicities along their long axes[28], giving them a beaded appearance, so do the bands of labelled cells. Figures 2*b* and 3*a* show bands of label in corresponding locations in V2 following two separate V4 injections. In the former case the bands are quite narrow (0.7 mm) and well circumscribed, but in the latter they are broader (~1.5 mm) and rather more diffuse. The relationship of these bands to the cytochrome oxidase stripes is often difficult to determine because the pattern can be

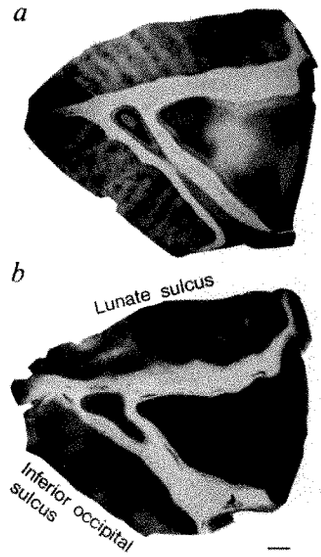

Fig. 2 *a*, Photomicrograph of a section taken through the flat-mounted occipital operculum and stained for cytochrome oxidase to show the thick and thin stripes and the interstripe zones in V2. The size of one cycle (centre-to-centre distance of two thin stripes) varies between 3.0 and 4.5 mm with a mean of 4.0 mm; the relative widths of the stripes also fluctuate, but are ~2:1:1.5 (thick:thin:inter). Not all macaque brains show such a clear pattern, especially in the lunate sulcus where the pattern is often complex and the thick and thin stripes are difficult to distinguish in individual sections. *b*, Dark-field photomicrograph of a similar section from a flat-mounted occipital operculum in an animal with an injection of HRP into V4. Note the striking similarity in the disposition of the labelled cells to that of the cytochrome oxidase stripes. The precise relationship of the two could not be determined in this brain, in which the cytochrome oxidase stain was unsatisfactory. Scale bar, 2 mm.

irregular, with alternate thick and thin stripes not easily discernible. Little could be learned from the cytochrome oxidase sections corresponding to the first case (Fig. 2*b*), in which the stain was technically poor; in the second case, where the staining pattern was irregular (Fig. 3*b*), superimposition of adjacent sections revealed that the labelled cells were centred over alternate stripes, and although overflowing into the interstripe zones, avoided the other set of stripes. That these were the thin stripes (those connected with the wavelength-selective blob of V1) was ascertained by tracing the pattern through a series of superimposed cytochrome oxidase sections, starting from those sections in which the stripes could be more clearly differentiated. This conclusion was reinforced by examination of another animal with a V4 injection, in which the two sets of stripes could be easily distinguished and in which a series of broad, if sparse, bands of label were again centred over thin stripes but avoided thick stripes (Fig. 3*d*). One further V4 injection again gave rise to the narrower bands of labelled cells and these were sited entirely in the interstripes. Four of these bands occupied 7.5 mm of cortex, a periodicity similar to that of the narrow bands of the brain in Fig. 2*b*, perhaps suggesting that these also might have a similar disposition with respect to the cytochrome oxidase stripes. This variation in the results obtained in V2 may reflect an inhomogeneity in V4 in relation to the distribution of wavelength and orientation selectivity[2,19]. The injection sites, although all in the posterior portion of V4, may have involved physiologically dissimilar regions.

Following injections into V5, labelled cells in V2 again appear in bands running orthognal to the V1/V2 boundary, but are now almost entirely confined to regions densely staining for cytochrome oxidase, which our evidence shows are the thick stripes. This was most clearly observed in the case of a brain sectioned horizontally (see Fig. 4*c*). The sections were drawn as described above and the information thus obtained was digitized along a

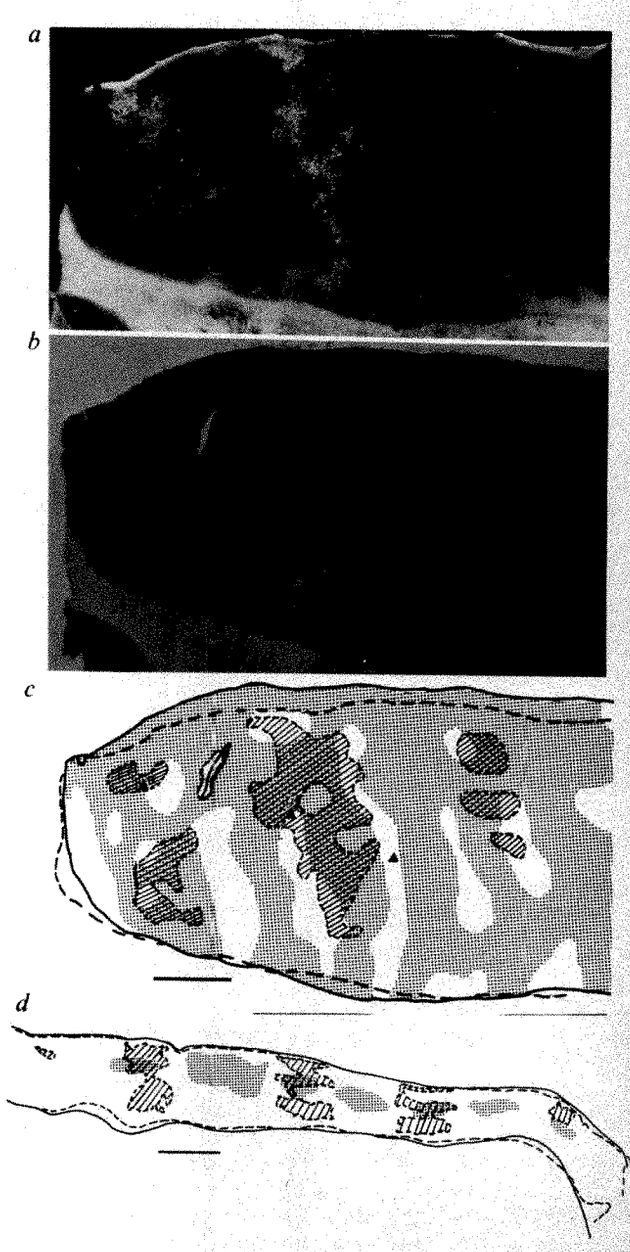

Fig. 3 *a*, Dark-field photomicrograph of the lunate sulcus from a flat-mounted operculum section to show the tangential distribution of labelled cells in V2 after an HRP injection into V4. *b*, Bright-field photomicrograph of a section next to the one shown in *a* and stained for cytochrome oxidase. *c*, Composite drawing, made from sections *a* (continuous outline) and *b* (interrupted outline) in which the two sections have been superimposed and areas of labelled cells (hatched) and dense stain (stippling) have been entered. The cytochrome oxidase distribution shown is also composite, drawn from superimposed images of section *b* and the other stained section next to *a*, a process that clarifies the pattern of stripes. Note that the labelled cells are centred over one set of stripes and skip alternate ones. We have not attempted to indicate more than one level of density for the distribution of either the labelled cells or of cytochrome oxidase, but it can be seen that both vary, not necessarily in parallel. For example, in the middle band of HRP-labelled cells (*b*) a roughly circular region of denser cytochrome oxidase staining coincides with a lower concentration of labelled cells. Unless traced over many sections, the stripes cannot, in this section, be identified as thick or thin. But *d* (a composite drawing made as for *c* but from sections from another brain with an HRP injection into V4), shows that the label is centred over the thin stripes and skips the thick ones. To align adjacent sections, as in *c* and *d*, we used blood vessels (three of which are indicated by triangles in *c*) and other landmarks to obtain the best fits, particularly because the shrinkage of the two sections is different in different directions.

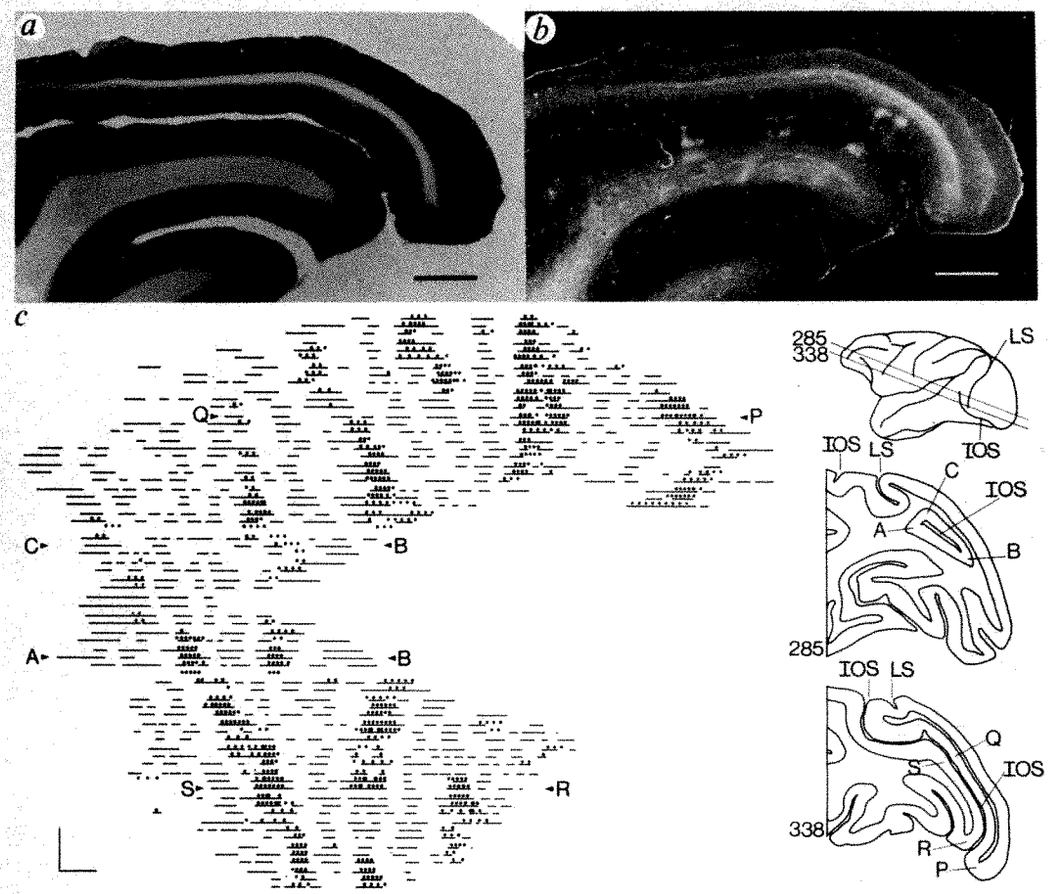

Fig. 4 *a*, Brightfield photomicrograph of a horizontal section taken through the part of V2 lying in the inferior occipital sulcus and stained for cytochrome oxidase activity. *b*, Darkfield photomicrograph, taken from an adjacent section, following HRP injection into V5. *c*, Computer-aided reconstruction made from many pairs of sections similar to *a* and *b*. The information in each pair of adjacent sections was incorporated into a single drawing (as in Fig. 3*c*) and this information was then digitized and entered in the computer. The distribution of cells is shown as dots, and regions densely stained for cytochrome oxidase as broken lines. The reconstruction is symmetrical about the fundus of the inferior occipital sulcus; each line represents one horizontal section, and the diagrams of sections 285 and 338 with the marked points, A, B, C, P, Q, R and S indicate how the overall configuration relates to the anatomy of the cortex. The cytochrome oxidase pattern is least clear where the stripes appear to be bifurcating, but elsewhere the appearance of alternate thick and thin stripes can be seen to emerge. LS, Lunate sulcus; IOS, inferior occipital sulcus. Scale bars: *a*, *b*, 2 mm; *c*, 1 mm for both axes.

'contour line' from the section and fed into a computer programmed to straighten and plot these lines to mimic the appearance that might have been obtained had the tissue been flattened and sectioned parallel to the cortical surface. The reconstruction reveals a number of irregularities, such as bifurcations in the stripes (which we have also observed in flat-mounted operculum cytochrome oxidase sections) but most of the stripes containing labelled cells are identifiably thick. This conclusion was in accord with the impression gained from those individual sections where alternating thick and thin regions of denser staining were visible, such as the lower bank of the inferior occipital sulcus in the section shown (Fig. 4*a*, the region between points 'R' and 'S' marked on its outline, labelled 338, in Fig. 4*c*).

In summary, we report here that alternating cytochrome oxidase stripes project to V4 and V5, our reconstructions suggesting that V4 receives input from the thin stripes and V5 from the thick, and that the interstripes also project to V4. Further evidence supporting functional distinctions between these subdivisions has come from our complementary physiological recordings (S.Z. and S.S., in preparation), in which we have made tangential penetrations running parallel to the stripes in the lunate sulcus. We have found that there is more variability in the responses recorded between penetrations than within any single penetration, and in several instances most of the units encountered in a single penetration, for a distance of over 1 mm, were either all orientation or all wavelength or all directionally selective. Where we have been able to associate penetrations with cytochrome oxidase stripes, we have found that interstripe cells are usually tightly tuned for orientation and are not wavelength-selective; most wavelength-selective cells, some of them double opponent, are found in or at the borders of thin stripes and are not orientation-selective. The frequency of occurrence of orientation selectivity is at an intermediate level in thick stripes, but these penetrations have the highest incidence of directional selectivity. Thick stripe cells, whether or not they are orientation-sensitive, generally respond equally well or better to spots of light moved in any direction than to long bars, unlike the orientation-selective cells of the interstripes, whose responses to spots are poor.

Thus, both anatomical and physiological evidence indicates that any operations performed in V2 must be performed separately for the different visual submodalities. This does not eliminate any interplay between the different pathways, given both local connectivities and that the outflow from V2, at least to V4, is not absolutely restricted to the territory of the thin stripes. But the segregation of pathways through V2 is much the more impressive and further reinforces the earlier evidence for functional specialization within the visual cortex[17].

This work was supported by grants from the SERC and the Wellcome Trust. We thank Ian Wilson for histological assistance.

Note added in proof: We have since found that V3, which has no wavelength-selective cells, also receives from cells in the thick cytochrome oxidase stripes of V2.

Complex–unoriented cells in a subregion of primate area 18

David H. Hubel & Margaret S. Livingstone

Department of Animal Neurobiology, Harvard Medical School, 25 Shattuck St, Boston, Massachusetts 02115, USA

In primates, both the primary and secondary visual cortical areas can be subdivided histologically by staining for the mitochondrial enzyme cytochrome oxidase[1–3]. In the primary visual cortex (area 17, the first cortical receiving area for visual information) these histological differences correspond to functional subdivisions[1–6], cytochrome-dark regions being concerned with information about colour and cytochrome-light regions concerned with form. Here we report that the second visual area, area 18, which receives its main cortical input from area 17 (refs 7, 8), similarly has functional subdivisions that correspond to the cytochrome oxidase staining pattern. In area 18 the segregation between form and colour is maintained, reinforcing our notion that form and colour information follow parallel pathways. The specific differences between cells in areas 17 and 18 suggest that a possible step in hierarchical information processing is spatial generalization, analogous to the difference between simple and complex cells.

In area 17 the cytochrome oxidase staining pattern consists of small dark-staining polka-dots (blobs) on a lighter-staining background[1,2]. Cells in the blobs are not orientation-selective and at least half are colour-coded, whereas most cells in the inter-blob regions are orientation-selective with only a small number colour-coded[6]. In area 18 the dark-staining regions are much coarser and form stripes, ~0.5–1 mm wide, which run perpendicular to the 17/18 border and extend the full width of area 18 to its anterior border (Fig. 1; refs 3–5). In some macaques and in most squirrel monkeys, the dark stripes are generally of two types, alternating thin and thicker, slightly lighter stripes. Although the thick stripes are not always easy to distinguish from the thin stripes by cytochrome oxidase staining alone, they differ anatomically in that they have a different laminar distribution of thalamic inputs[4]. Thus, area 18 seems to consist of at least three types of subregions: thin stripes, thick stripes and, in between, much lighter interstripes.

We have recorded from 1,019 cells in area 18 of 11 young adult female *Macaque fascicularis* monkeys and 7 adult female *Saimiri sciurius* (squirrel) monkeys. The recording apparatus was as described previously[6]. We made electrode penetrations perpendicular to the cytochrome oxidase stripes as nearly parallel to the surface as possible.

It was clear that area 18, like area 17, is physiologically heterogeneous but with a much coarser periodicity. Figure 2 shows the results from one macaque monkey, in which we recorded from 9 mm of area 18; almost all of the penetration appears in this single section. The figure indicates that we passed through four cytochrome oxidase-dark regions. Two of these stripes (the second and fourth) consisted exclusively of cells that entirely lacked orientation selectivity, whereas almost all the cells in the other two stripes and in the interstripe regions were orientation-selective. We found such long stretches of

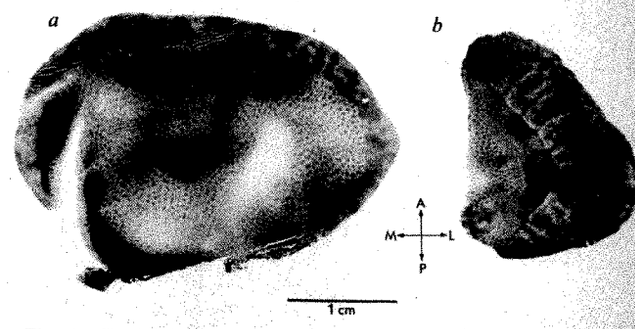

Fig. 1 Sections of monkey visual cortex stained for cytochrome oxidase. *a*, Section from a macaque monkey. Most of the section is in area 17 except for a 0.5-cm-wide strip of area 18 at the top. *b*, Section from a squirrel monkey. Area 17 is to the left with the fine polka-dot pattern and area 18 is to the right with a coarser-striped pattern. The alternation of thick and thin stripes is clearest near the top of the squirrel monkey section and is not apparent in the macaque.

unoriented cells in both macaques and squirrel monkeys (211 cells), always in cytochrome oxidase-dark regions. In the macaques it was not usually possible to say whether the dark stripes containing unoriented cells were thick or thin, but they usually alternated with stripes containing oriented cells, as in Fig. 2. In the squirrel monkeys the unoriented cells were clearly in the thin stripes. All these results are consistent with our earlier observation that the blobs in area 17 and thin stripes in area 18 are interconnected.

In macaques, about two-thirds of the unoriented cells showed colour opponency; in the squirrel monkey the proportion of colour-coded cells was much smaller. Of the colour-coded cells, a few had colour opponent centres and no antagonistic surrounds (for example, red-on centre, green-off centre, Type II; ref. 6), but most had some form of double-opponent colour coding (for example, red-on centre, red-off surround, green-off centre, green-on surround). Similar to blob cells in area 17, the unoriented cells in area 18 (whether or not they are colour-coded) responded more strongly as spot size was increased up to an optimum size beyond which the responses declined. What was different about many of these cells, compared with the blob cells in area 17, is that they responded to a spot of optimum size regardless of where it was positioned, over an area that was itself many times larger than the optimum spot. Thus, in these cells a spot large enough to cover the entire activating region was usually ineffective.

An example of one such colour-coded cell is shown in Fig. 3. It gave on responses to small red spots, off responses to small blue or green spots and no responses to white or to yellow spots (580 nm). In response to an optimal spot, 0.5° in diameter, the cell gives on responses to red and off to blue or green throughout an activating region 3.5° in diameter, maximum near the centre and falling off gradually with distance; increasing the spot beyond 0.5° resulted in a fall-off in responses (Fig. 3*b*, *c*). When we shone a small red and a small blue spot simultaneously in the same position (giving a yellow spot), the cell gave little or no response. We did not try spatially to separate red and blue spots with this cell (but in other similar cells, simulating with a small red spot and a small blue spot side-by-side within the activating region gave mixed on/off responses). This cell was located in layer 5 of a cytochrome oxidase-dark stripe in area 18 of a macaque.

We also observed cells, similar but not colour-coded, some giving on and others off responses regardless of wavelength over an activating region larger than the optimum spot size. Baizer *et al.*[9] have described 'spot cells' in area 18 that are similarly unoriented, not colour-coded and respond best to a small spot anywhere in a large receptive field. We term all of these cells, whether or not they are colour coded, 'complex-unoriented', because they differ from ordinary centre-surround cells in a manner analogous to the difference between oriented simple and complex cells[10]. (The distinction lies in the permissible

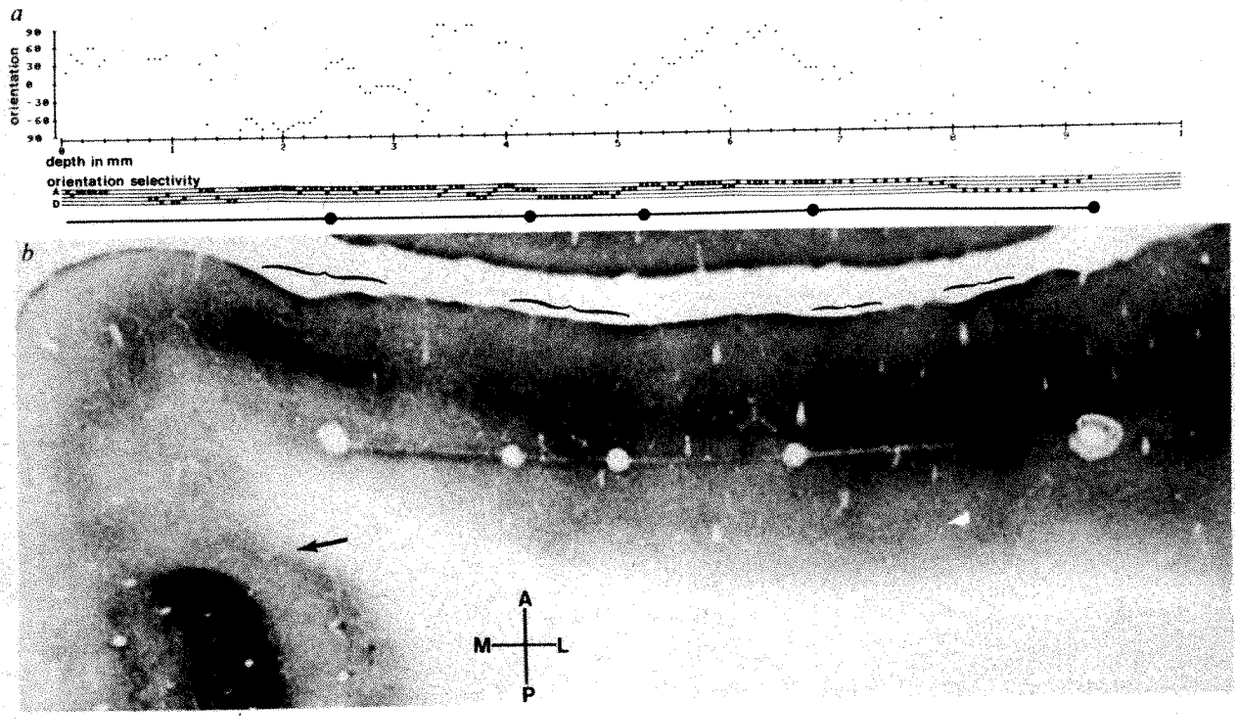

Fig. 2 *a*, *b*, Reconstruction of an electrode track in area 18 of macaque. *b*, Transverse section through area 18 just anterior and parallel to the area 17/18 border. Part of the border is visible at the left edge of the section (arrow). The space shown just above area 18 is the lunate sulcus; the midline is on the left. The electrode track, most of which can be seen together with five electrolyte lesions, runs from left to right. The section was stained for cytochrome oxidase[22] and the cytochrome-dark regions are indicated by brackets. *a*, From above downwards, preferred orientation (0°, vertical); orientation selectivity (A, well oriented, D, unoriented); and the location of the electrolyte lesions. Optimum orientation and orientation selectivity were judged subjectively by listening to the response of the cell to slits of light generated by a hand-held slide projector. Observations were made every 0·05 mm. Note the correspondence between two of the cytochrome-dark regions (between second and third lesions and just before the final lesion) and the absence of orientation selectivity. (At these points no orientation could be plotted.) The entire track after the first 0.5 mm was below layer 4.

variation in position; see ref. 10.) In both cases, although the size of the region of the visual field in which the higher level cell can be activated is larger (in our complex-unoriented cells, from two to several times the diameter), the optimum stimulus size for a given eccentricity remains the same, as if an 'or-gate' operation had been performed on many cells with similar receptive fields scattered over an area larger than each separate receptive field. Thus, although resulting in a loss of precision of localization, complexification need not lead to a loss of resolution or acuity, because at a given eccentricity the average optimum stimulus size, such as line width or spot diameter, shows no such increase. The increase in receptive-field size reported in several pre-striate areas[11–14] is presumably, at least in part, the result of such transformations. The occurrence of similar operations in different systems suggests that similar circuits are used, which would doubtless simplify the problem of building the cortex. Despite the frequency with which this operation seems to occur in the visual system, its role in information processing is still a matter of conjecture. (See page 285 of this issue.)

Some of the unoriented cells we found in area 18 were not complex and seemed the same as cells that we have observed in area 17. We are now trying to determine whether the different orders of unoriented cells in area 18 are segregated into different layers, as any sequence of unoriented cells tended to contain either ordinary or complex unoriented cells. In area 17, however, we have not seen complex-unoriented cells. The transformation of colour information in going from area 17 to 18 might be predicted to involve the acquisition of orientation selectivity, but this seems not to be so.

In the squirrel monkey it is clear that the regions in area 18 containing complex-unoriented cells are the same regions, the thin stripes that we previously found anatomically to be connected to the blobs in area 17. These blobs contain unoriented, often colour-coded cells[6]. In macaque monkeys the histological distinction between two types of cytochrome-dark stripes is often less clear, but, as shown in Fig. 2, only some of the stripes (usually alternate ones) are also characterized by colour-coded unoriented cells.

We have also studied the characteristics of the cells in the other stripes: cells in both the interstripes and the thick stripes show orientation selectivity and are not colour-coded. The light-staining interstripes in area 18 are reciprocally connected with the inter-blob regions of area 17, which contain oriented non-colour-coded cells[6]; the connections of the thick stripes are not yet known, but they clearly receive input from area 17 (see Fig. 30 of ref. 6). The most striking characteristic of cells in the interstripe regions is that over half of them are end-stopped[11], responding optimally to slits of a particular length and less well to longer slits. This suggests that the system that in area 17 carries information about the orientation of edges might next acquire information about their degree of curvature. In the thick stripes the cells seem to be concerned primarily with binocular disparity: many fail to respond to either eye alone but do respond if the eyes are aligned with a particular disparity, corresponding either to near, far or peaking at zero disparity. DeYoe and Van Essen[15], by injecting two different retrograde tracers into the pre-striate visual areas MT and V4 of macaques, have found that in area 18 alternating cytochrome-dark stripes project to MT and to V4. The results of Shipp and Zeki[16] in the accompanying paper confirm these observations. Given the high proportion of colour-coded cells reported in V4 (ref. 14), the V4-projecting stripes would be expected to be the ones to receive input from the blobs in area 17 and contain unoriented, often colour-coded cells: in a squirrel monkey these would be the thin stripes. Our finding that the thick stripes contain orientation-selective cells is consistent with their involvement with some system other than the colour system; they could correspond to the MT-projecting stripes described by DeYoe and Van Essen[15]. The segregation in area 17 of two systems, one apparently concerned with form

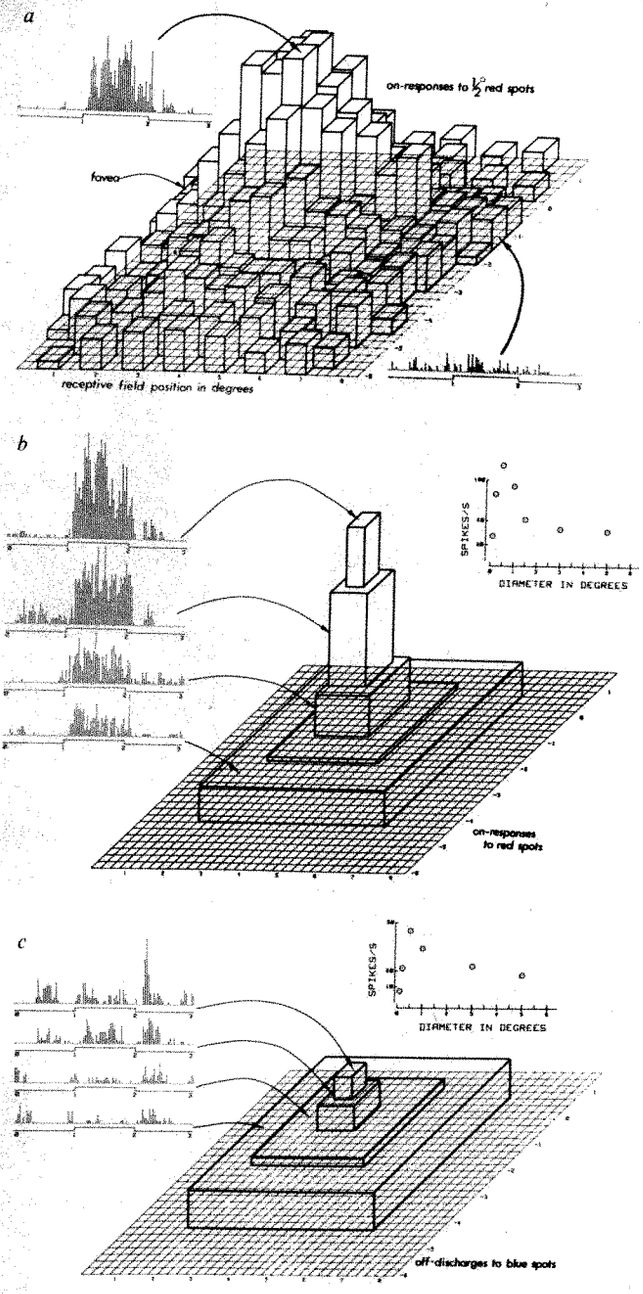

Fig. 3 Responses of a complex double-opponent cell in area 18 of a macaque monkey to red and blue spots of light, varying size and position of spot. The grid represents the visual field, marked off in degrees, with the fovea at (0, 0). The red and blue spots were produced by Kodak Wratten filters (29 and 47B) placed in front of a slide projector. *a*, Three-dimensional plot illustrating responses to red spots of optimal size, 0.5° in diameter. The plot is made over a region 8×8°, centred 5° lateral and 2.5° below the fovea. Responses were obtained over an area occupying 3×3°, outside which the bars represent spontaneous background activity. Bars represent means of five responses to stimuli of 1 s duration. The histogram for the area giving the peak response, shown in the inset on the upper left, represents 85 impulses during this 'on' period. The lower right inset shows one of the histograms for a region giving little or no response above the background firing rate. *b*, Diagram of on-responses to red light spots of various sizes. Each histogram is a mean of five stimuli. The three-dimensional graph illustrates the responses to the optimum size and to larger stimuli; the inset on the left shows the histograms obtained for four of these five spots. The upper right inset shows the entire curve of response versus spot size. Note that the 3.5 and 5° stimuli evoked responses that were barely visible above background firing levels, even though these covered the area over which 0.5° spots gave vigorous responses. *c*, Same cell, off-discharges to blue spots of different sizes.

and the other with colour, evidently persists into area 18 and beyond. That a similar segregation occurs in humans is apparent from reports of subjects with local cortical damage who experience loss of colour vision but retain normal form, movement and depth perception[17–21].

Induction of regulatory T-lymphocyte responses by liposomes carrying major histocompatibility complex molecules and foreign antigen

Peter Walden, Zoltan A. Nagy & Jan Klein

Max-Planck-Institut für Biologie, Abteilung Immungenetik, Corrensstraße 42, 7400 Tübingen, FRG

Regulatory (helper and suppressor) T lymphocytes become activated only when foreign antigen is presented to them on the surface of antigen-presenting cells (APC), together with class II major histocompatibility complex (MHC) molecules (heterodimers of polypeptides of 28,000 and 35,000 relative molecular mass)[1–4]. Once activated by a certain foreign antigen—MHC combination, T cells react to the same antigen only in combination with the same MHC molecule, a phenomenon termed MHC restriction of T-cell recognition (reviewed in refs 1, 5). Studies of the mechanisms involved in antigen presentation and MHC restriction have been hampered mainly by the virtual impossibility of inducing T-cell responses in the absence of APC. We describe here the production of synthetic lipid vesicles with inserted class II MHC molecules and a protein antigen coupled covalently to the lipid. These liposomes are shown to stimulate cloned helper T cells and T-cell hybridomas in an antigen-specific, MHC-restricted manner in the absence of APC. Thus, the recognition of foreign antigen together with class II MHC molecules seems to be the only signal required for the activation of antigen-primed regulatory T cells. Furthermore, 'processing' of antigen by APC is not essential for its recognition by T cells.

To determine the minimal requirements of T-cell activation, we constructed liposomes carrying a foreign protein antigen, or class II MHC molecules, or both, and tested whether these liposomes could activate antigen-specific class II-restricted T cells in the absence of APC. Class II MHC molecules were isolated from lipopolysaccharide-stimulated spleen cells. The membrane proteins were solubilized with 50 mM β-octyl gly-

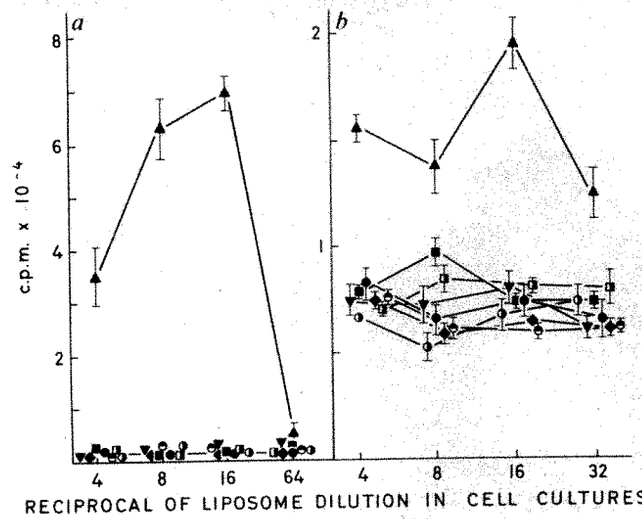

Fig. 1 Liposome-bound antigens induce the proliferative response of an ovalbumin (OVA)-specific, A^b-restricted T-cell clone (*a*) and IL-2 production by a bovine insulin (BI)-specific A^b-restricted T-cell hybridoma (*b*). Liposomes with the following proteins were used: ▲, *a*, OVA + A^b; *b*, BI + A^b; ■, *a*, OVA; *b*, BI; ●, *a* and *b*: A^b; ▼, mixture of liposomes with: *a*, OVA and A^b; *b*, BI and A^b; ◨, *a*, OVA + A^k; *b*, BI + A^k; ◑, *a*, BI + A^b; *b*, OVA + A^b; ◓, *a*, free OVA + A^b; *b*, free BI + A^b; ◆, liposomes without protein. Each point represents the arithmetic mean ± s.d. (vertical bars; not shown where too small to be represented graphically) of triplicate cultures. Control values (c.p.m. ± s.d.) for the proliferative response of OVA-7 (*a*) and for the IL-2 production by hybridoma 52H10F11 (*b*): feeder cells, *a* (C57BL/6), 654 ± 124; *b* (C57BL/6), 6,505 ± 522; antigen, *a* (OVA, 100 μg ml^{-1}), 1,821 ± 205; *b* (BI, 200 μg ml^{-1}), 5,623 ± 522; antigen + feeder cells, *a* (OVA 100 μg ml^{-1} + C57BL/6), 202,066 ± 12,019; *b* (BI 200 μg ml^{-1} + C57BL/6), 140,381 ± 1,727; control antigen + feeder cells, *a* (BI + C57BL/6), 657 ± 366; *b* (OVA + C57BL/6), 6,976 ± 611; antigen + control feeder cells, *a*, not done; *b* (BI + B10.A), 5,162 ± 542.

Methods. Clone OVA-7 of C57BL/6 origin (M. H. Schreier, unpublished data) was precultured with IL-2 and without feeder cells for 6 days, washed and distributed in 0.2-ml wells (3×10^4 cells per well), cultured in the presence of liposomes for 3 days (without IL-2 and feeder cells), and proliferation was measured by ^{3}H-thymidine incorporation[26]. Hybridoma 52H10F11 (BI-specific, A^b-restricted; B. Huber, unpublished data) was cultured (5×10^5 cells ml^{-1}) in the presence of liposomes for 2 days. Supernatants were then collected and tested for their capacity to induce proliferation of the IL-2-dependent cell line CTLL[27] (5×10^3 cells per well, 1 day's culture followed by a 16-h pulse with 2 μCi per well of ^{3}H-thymidine). Culture medium was α minimal essential medium supplemented with 10% fetal calf serum, antibiotics, L-glutamine and 3×10^{-5} M 2-mercaptoethanol. Liposomes were prepared by the dialysis method[7,28]. They consisted of dipalmitoylphosphatidylethanolanine (DPPE), 10% of which was SPDP-modified (the efficiency of modification was 1–1.5%). Liposomes were allowed to react with a large excess of SPDP-coupled OVA and BI, respectively (2.5 mg to 12.5 mM lipid). The antigen-coupled liposomes were purified by sucrose gradient centrifugation (5–45% flotation gradient, 100,000*g*, 46 h). The density of antigen on liposome was monitored by the position of the liposome band in the gradient. Class II MHC molecules were purified by affinity chromatography using monoclonal antibodies 17.227.R7 (ref. 29) for the A^b, and 10.2.16 (ref. 30) for the A^k molecule.

copyranoside in 10 mM Tris-buffered saline solution. Further purification was performed by affinity chromatography according to the procedure described by Turkewitz *et al.*[6], with the modification that β-octyl glycopyranoside was used as a detergent throughout. Monoclonal class II-specific antibodies used for the affinity columns were coupled with Sepharose-4B by the cyanogen bromide method followed by fixation with glutaraldehyde. The one-step affinity chromatography yielded highly enriched class II preparations with minor contamination by other proteins, as judged by SDS-polyacrylamide gel electrophoresis (data not shown). The class II molecules were inserted into liposomes made of synthetic lipids as described elsewhere[7,8]. Lipids in the liposomes were activated by thiolation with *N*-succinimidyl 3(-2-pyridyldithio)propionate (SPDP) via a disulphide bond as described previously[9,10]. The foreign protein antigens used were attached to these SPDP-activated lipids. The liposomes thus obtained carried class II MHC molecules inserted into the lipid bilayer by their hydrophobic transmembrane portion, and protein antigens covalently linked to the lipids. The vesicles were further purified by ultrafiltration, ultracentrifugation and in some experiments by flotation on a sucrose gradient. Flotation experiments were also performed to monitor the efficiency of reconstitution of MHC molecules into, and coupling of antigens to, the liposomes.

Figure 1 demonstrates that only the liposomes carrying both the priming antigen and the appropriate MHC molecules are able to stimulate proliferative response of an ovalbumin-specific, A^b-restricted T-cell clone, and interleukin-2 (IL-2) production by an insulin-specific, A^b-restricted T-cell hybridoma, in the absence of APC. Thus, the recognition of antigen + MHC molecules alone seems to provide a sufficient signal to induce these two kinds of responses of helper T cells. Note that, for a response to occur, the antigen and MHC molecules must be incorporated into the same liposome, indicating that the receptor structure of T cells recognizes these two moieties together. The finding that mixtures of antigen-bearing and MHC-bearing liposomes are not stimulatory, together with the results of other control groups of the experiments (MHC-bearing liposomes presented together with free antigen; antigen-bearing liposomes alone) makes it very unlikely that the liposomes are taken up and re-presented by residual APC or by the T cells themselves. Further evidence to rule out this possibility will be presented elsewhere (P.W., Z.A.N. and J.K., in preparation).

Our data extend previous results from several laboratories that demonstrated that secondary cytolytic T-cell responses and secondary mixed lymphocyte reactions can be stimulated by cell-free antigens, although in these experiments the possibility that APC contributed to the T-cell activation could not be excluded[11–18]. Our results also agree with a recent report by Malissen *et al.*[19] that the expression of transfected class II MHC genes seems to be the only requirement to convert a cell into an APC. The fact that intact protein molecules, when coupled to lipid, can activate T cells indicates that extensive processing is not required to render a protein immunogenic for T cells. Thus, although antigen degradation certainly takes place in macrophages and perhaps also in other cell types[20,21], and although the existence of T-cell clones with a preference for partially digested antigens has been demonstrated[22,23], the notion that regulatory T cells are capable of recognizing only degraded (or processed) antigen[24,25] is not generally valid.

We thank Drs B. Huber and M. H. Schreier for their generous gift of cell lines, and Ms G. Labib for technical assistance. This work was supported in part by SFB 120/A.5 from the Deutsche Forschungsgemeinschaft.

Developmental acquisition of Ca^{2+}-sensitivity by K^+ channels in spinal neurones

Leslie A. C. Blair* & Vincent E. Dionne†‡

Departments of Biology and ‡Medicine, University of California, San Diego, La Jolla, California 92093, USA

A developmental change in the ionic basis of the inward current of action potentials has been observed in many excitable cells[1]. In cultured spinal neurones of *Xenopus*, the timing of the development of the action parallels that seen *in vivo*[2,3]. *In vitro*, as *in vivo*, neurones initially produce action potentials of long duration which are principally Ca-dependent; after 1 day of development the impulse is brief and primarily Na-dependent[3-5]. At both ages, however, both inward components are present[4-6] and the mechanism underlying shortening of the action potential is unknown. One possibility is that the outward currents change during development. Using the patch-clamp technique[7], we have recorded single K^+-channel currents in membrane patches isolated from the cell bodies of cultured embryonic neurones[3]. The unitary conductance of one class of K^+ channels was ~155 pS and depolarization increased the probability of a channel being open. Neither conductance nor voltage dependence seemed to change with time in culture; in contrast, the Ca^{2+}-sensitivity of this K^+ channel increased. In younger neurones, Ca^{2+}-sensitivity was greatly reduced or absent, whereas in more mature neurones, the activity of this channel was Ca-dependent. Such a change could account for the shortening of the action potential duration by increasing the relative contribution of outward currents.

Single-channel currents of *Xenopus* neurones were recorded at two stages of development in culture: early (7-11 h) and mature (22-43 h). All recordings were made from inside-out excised patches at room temperature. In most cases, K^+ was the predominant monovalent cation in both pipette and bath solutions. Channel activity during prolonged depolarization was characterized by bursts of openings interrupted by brief closures and followed by long closed intervals. The unitary conductance was estimated from the single-channel current/voltage (I-V) relationship. After 1-2 days in culture, a channel with a conductance of 156 ± 2 pS (mean ± s.e.m.) was observed in 15 patches. Unitary conductance was independent of membrane potential (±50 mV), of internal Ca^{2+} concentration ($[Ca^{2+}]_i$ = 0.5-100 μM), and of external Ca^{2+} concentration ($[Ca^{2+}]_o$ = 0-0.5 mM). Similarly, at early ages a channel with a unitary conductance of 154 ± 2 pS was observed in nine patches; conductance was independent of calcium concentration and membrane potential.

At both ages these channels selected primarily K^+ ions. Currents reversed direction at the K^+ equilibrium potential (E_K), both in symmetrical K^+ and when $Tris^+$ was partially substituted for internal K^+, shifting E_K to +17.5 mV ($n = 6$ patches at 1-2 days; $n = 6$ patches at 7-11 h). However, when recordings were made in saline solution with Na^+ as the predominant extracellular cation and K^+ primarily on the intracellular face (E_K = −75 mV), unitary currents reversed at an extrapolated potential of ~−50 mV ($n = 5$ patches, 1 day in culture). If the channel is assumed to be permeable to Na^+ as well as K^+, the relative Na^+/K^+ permeability, calculated from the Goldman-Hodgkin-Katz equation, was 0.08-0.1. An alternative explanation for the apparent imperfect selectivity is that the I-V relationship was nonlinear in the area of E_K.

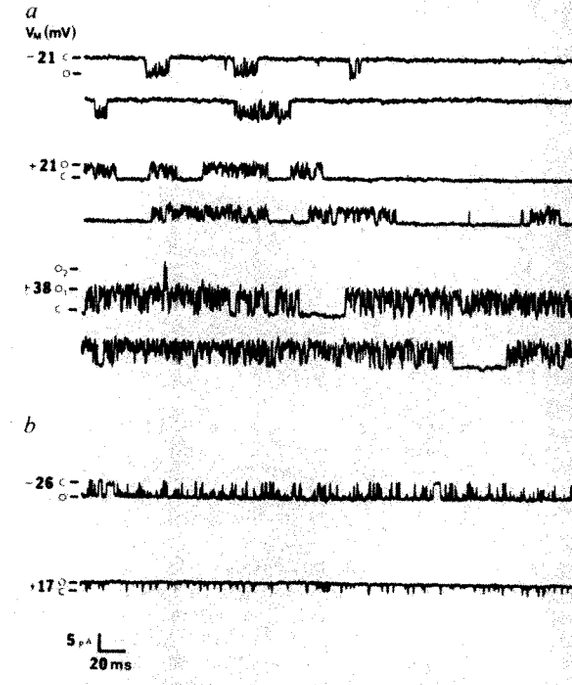

Fig. 1 Calcium- and voltage-sensitivity of K^+ channels in an 'inside-out'[7] patch excised from a neurone after 23.5 h in culture. *a*, Single-channel currents recorded with 1 μM Ca^{2+} at the intracellular surface. Openings occurred in bursts separated by long quiescent periods: O, open; C, closed. Burst durations increased and inter-burst intervals decreased with depolarization. Single-channel conductance was 158 pS. *b*, Increasing the $[Ca^{2+}]_i$ to 10 μM increased burst duration and decreased inter-burst closed intervals. At E_m = +17 mV, channels were almost continuously open. Same patch as in *a*. Multiple simultaneous openings occurred at depolarized potentials, indicating that a minimum of three channels were active in the patch (not illustrated). Activity of smaller-amplitude channels was not observed. During a burst there were many brief closures which were poorly resolved. Some of these apparent closures may have been only partial, to a lower-conductance substate. Membrane potential was varied by resetting the holding potential across the patch. Data were filtered at 4 kHz, sampled at 50-μs intervals, and recorded in 460.8-ms segments.
Methods. Neurones were cultured from dissociated *Xenopus* neural plates (Nieuwkoop and Faber stage 15)[16] as described previously[3,4], and single-channel currents were recorded at room temperature using established techniques[7,17,18]. Data were analysed for current amplitudes by computer[17,18]; the threshold for event detection was 50% of the mean amplitude. Burst duration and inter-burst intervals were measured by hand from a chart record of the data. Unless otherwise stated, the saline solution in the pipette and in the bath comprised (in mM): 150 KCl, 10 or 1 EGTA (results were indistinguishable), 5 HEPES, *p*H 7.8. Free internal Ca^{2+} concentrations of 0.5, 1, 10, 25 and 100 μM were achieved by adding $CaCl_2$ to the bath saline These concentrations were calculated assuming purity of the EGTA (but see ref. 19). Bath volume was 0.2 ml; bath changes were achieved by washing the patches with ≥25 vol. saline.

Embryonic *Xenopus* neurones exhibited a marked developmental difference in the effect of internal calcium on the activity of this channel. At 1-2 days, activity was sensitive to $[Ca^{2+}]_i$ (Fig. 1). Opening was not detected when free $[Ca^{2+}]_i$ was estimated to be $<10^{-10}$ M. Raising the $[Ca^{2+}]_i$ from 1.0 to 10 μM or from 0.5 to 25 or 100 μM substantially increased channel activity ($n = 12$ of 14 patches): both burst duration and the number of simultaneous openings increased, while the inter-burst intervals decreased. In the experiment shown in Fig. 1, raising the $[Ca^{2+}]_i$ from 1.0 to 10 μM increased the mean burst

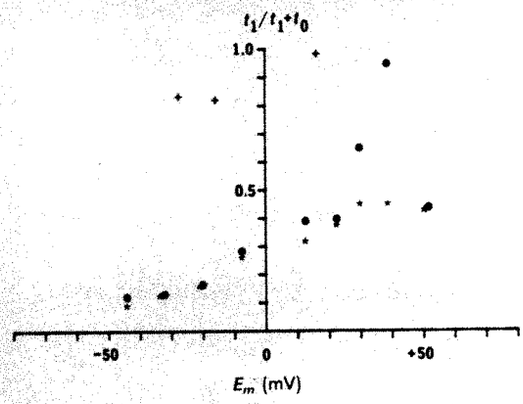

Fig. 2 The fraction of time for which one channel was open changed with membrane potential, $[Ca^{2+}]_i$, and the length of time after a change in membrane potential. This fraction was calculated as t_1/t_1+t_0 in which t_1 is the time for which a unitary level of channel activity was observed, t_0 the time in which no activity was observed. In 1 μM calcium, the fraction of time spent open increased with depolarization (●). Increasing the $[Ca^{2+}]_i$ to 10 μM increased this fraction several-fold (+). The fraction decreased during the recording in a time- and voltage-sensitive manner, presumably as a result of inactivation. In 1 μM calcium, the fraction was compared between the first 460.8 ms (●) and the section 2.9–3.4 s into the record (*); a large reduction was observed at depolarized voltages. At 38.1 mV, this reduction occurred within the first second of recording; at less depolarized voltages, the reduction was slower as well as smaller. The low initial activity seen at +50.3 mV probably results from inactivation during the ~1-s delay between setting the membrane potential and the start of recording. Ending depolarization, then re-stepping to positive potentials regenerated high levels of activity. Data are from the patch shown in Fig. 1.

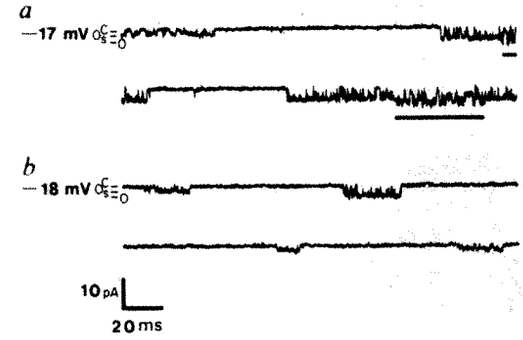

Fig. 3 Ca^{2+}-insensitive K^+ currents recorded from an inside-out patch of membrane excised from a neurone at 8.5 h. *a*, Single-channel currents at −17 mV were recorded in the absence of intracellular calcium; *b*, single-channel activity at −18 mV in 100 μM calcium. These records also illustrate the presence of a smaller-amplitude K^+ channel which was Ca^{2+}-insensitive at all ages and appeared to be independent of the ~155-pS channel studied here. O, opening of a 155-pS channel; O_s, opening of a smaller-conductance K^+ channel; C, closed. The dark bars denote regions of simultaneous opening of both the large- and small-amplitude channels. Data were filtered at 2.5 kHz and digitized at 100-μs intervals.

duration almost 15-fold; the mean inter-burst interval decreased ~30-fold (at membrane potential (E_m) = +17 mV). This resulted in a large increase in the fraction of total time for which a channel was open (Fig. 2). Different results were obtained from 2 of the 14 patches: in one case, channel activity appeared to be insensitive to change in the $[Ca^{2+}]_i$; in the other, few openings were observed until $[Ca^{2+}]_i$ was raised to 100 μM, but reducing the $[Ca^{2+}]_i$ subsequently failed to decrease the frequency of opening.

In contrast to the Ca^{2+}-sensitive activity observed in patches from mature neurones, channel activity in patches excised from early neurones was insensitive to changes in $[Ca^{2+}]_i$ ($n = 9$ patches). Currents were observed with free $[Ca^{2+}]_i < 10^{-10}$ M (Fig. 3), and increasing the $[Ca^{2+}]_i$ to 100 μM did not change the fraction of time for which a channel was open. In six additional patches no channel activity was observed in Ca^{2+}-free saline; raising the $[Ca^{2+}]_i$ to 100 μM did not induce activity. Extracellular calcium had no effect on channel activity of either early or mature neurones.

Activity at both ages was voltage-dependent. Figure 2 shows that the fraction of time for which a channel was open increased with depolarization. In addition, the mean inter-burst closed time declined and the mean burst duration increased, suggesting that the increase in open time of the channels was due both to an increased probability of opening to a burst and to a decreased probability of closing, once opened. In other patches, the fraction of time spent open showed sigmoidal increases with depolarization similar to that in Fig. 2; the half-maximal value was attained at ~+20 mV in all cases. The frequency of occurrence of bursts showed comparable voltage-dependence.

Most patches also possessed a lower-conductance K^+-selective channel: 94 ± 3 pS at day 1 ($n = 4$ patches); 93 ± 1 pS at 8.5–10.5 h in culture ($n = 4$ patches; Fig. 3). Opening of this channel was not correlated with that of the larger channel. The fraction of time for which the channel was open and the frequency of bursting were unaltered by changes in $[Ca^{2+}]_i$ but increased with depolarization. The half-maximum of the fraction of time spent open occurred at ~0 mV. Although lower conductances have been reported in other neural preparations[8,9], this channel may represent a delayed rectifier.

The Ca^{2+}-sensitive K^+ currents observed in these neurones at 1–2 days in culture appear to be similar to those of other preparations. Unitary conductances of 100–220 pS[8,10–12] at room temperature, calcium- and voltage-independence of the conductance[10], and calcium- and voltage-sensitive changes in bursting[10,13,14] have been reported, but inactivation was not prominent[10,13].

The results reported here suggest that the acquisition of calcium-sensitivity accounts in part for the developmental disappearance of the Ca^{2+}-dependent plateau of the action potential. The lack of age-dependent changes in unitary conductance, K^+-selectivity and voltage-dependence of activation suggests that the Ca^{2+}-sensitive and -insensitive channels represent a single class of channel, the gating mechanism of which is developmentally modified. Different sensitivities could be produced through mechanisms ranging from activation of a multigene family to post-translational modification. The infrequent presence of Ca^{2+}-insensitive channels in older neurones could indicate that these channels are inserted into the membrane in a form having reduced sensitivity and are then modified, or that a population of Ca^{2+}-insensitive channels persists into late stages of development. In view of recent results with the acetylcholine receptor[15], it would be of interest to see whether blockers of glycosylation or phosphorylation prevent the appearance of Ca^{2+}-sensitivity.

To date no nucleic acid has been found in the purified infectious agent which causes the spongiform encephalopathy known as scrapie. In an attempt to identify a unique scrapie virus-associated messenger RNA in tissues of infected animals, we have synthesized an oligonucleotide probe complementary to the mRNA sequence corresponding to the amino-acid sequence of the prion protein, PrP27–30 (ref. 1). We report here that, with this probe, a complementary DNA clone representing PrP27–30 was obtained from scrapie-infected mouse brain; the DNA sequence of this clone could be translated into a protein that matches exactly the published sequence of PrP27–30. The cDNA clone hybridized to a single 2.4–2.5-kilobase (kb) mRNA from both normal and scrapie-infected brain. Thus, the PrP27–30 mRNA is not uniquely associated with scrapie infectivity, suggesting that PrP27–30 may be a normal component of mouse and hamster brain.

Scrapie is a slowly progressive spongiform encephalopathy of sheep and goats[2] which can be transmitted to a variety of animal species including mice, hamsters and mink[3]. The pathology of scrapie is similar to certain devastating dementias of humans such as kuru, Creutzfeldt-Jacob disease and Gerstman-Straussler syndrome[4–6]. The replicating infectious agent which causes these diseases has many properties similar to those of a virus[7], but has not shown sufficient biophysical homogeneity to allow adequate purification for precise biochemical analysis[8,9]. Thus, the presence of a viral nucleic acid has not yet been demonstrated. In fact, in the case of scrapie, it has been proposed that the agent may consist solely of protein, and the term 'prion' has been coined to describe such proteinaceous infectious particles[10–12]. Recent studies have suggested that scrapie infectivity is associated with large characteristic fibril structures[13], termed scrapie-associated fibrils[14] or rods[15], which have a unique morphology when negatively stained and examined under the electron microscope but share some of the properties of amyloid which is a major feature of brain pathology in some scrapie models[16]. The proteins in these structures isolated from hamster scrapie have also been analysed serologically and biochemically and consist mainly of a polypeptide of relative molecular mass 27,000-30,000, PrP27-30 (refs 1, 13, 14, 17). The N-terminal 15 amino acids of this protein have been sequenced and show no homology with other known proteins[1]. Based on this amino acid sequence, we have synthesized a mixture of oligonucleotides for use as a hybridization probe to analyse mRNA populations derived from infected and uninfected animals and to identify unique scrapie virus-encoded mRNA species.

‡ Present address: Division of Bacterial Diseases, Centers for Disease Control, Atlanta, Georgia 30333, USA.

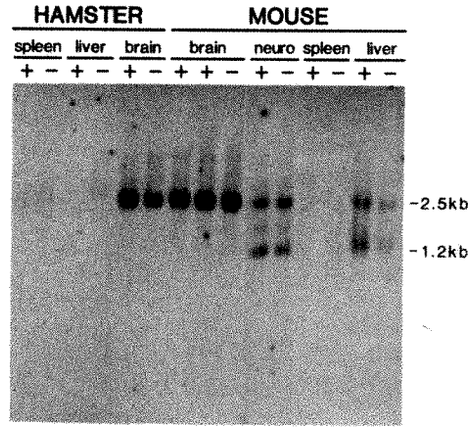

Fig. 1 Identification of scrapie-specific mRNA in infected (+) and uninfected (−) animals. Messenger RNA was isolated from RML outbred mice and Syrian hamsters who showed clinical neurological symptoms 120–150 days (mouse) or 65–75 days (hamster) after intracerebral inoculation of $10^{6.8}$ (mouse) or 10^9 (hamster) infectious units of scrapie. The mouse-adapted Chandler strain of scrapie was obtained from Dr W. J. Hadlow (RML). Hamster-adapted scrapie was obtained from Dr S. Prusiner, University of California School of Medicine, San Francisco. mRNA from uninfected, age-matched animals and from scrapie-infected and uninfected cells of a mouse neuroblastoma cell line (clone NA, obtained from Dr D. Lodmell, RML), was also isolated. Tissue culture cells, brain, spleen and liver tissue were homogenized in 5 vol. of 4 M guinidinium isothiocyanate and disrupted briefly in a blender[30]. RNA was pelleted by centrifugation through 5.7 M CsCl in 0.1 M EDTA at 35,000 r.p.m. for 16 h at 20 °C in a Beckman SW50.1 rotor. For brains, the RNA pellet was resuspended in 1% SDS, 10 mM Tris-HCl *p*H 7.4, 5 mM EDTA and extracted with 4:1 chloroform/1-butanol. The aqueous phase was brought to 0.3 M sodium acetate and RNA precipitated with 2.5 vol. ethanol at −20 °C. For liver and spleen, the RNA pellet from the CsCl spin was resuspended in 7.5 M guanidinium-HCl, 20 mM sodium acetate *p*H 7.0 and 1.0 mM dithiothreitol (DTT) and precipitated with 0.5 vol. ethanol at −20 °C. The pellet was resuspended in water, brought to 0.3 M with sodium acetate and precipitated with 2.5 vol. ethanol at −20 °C. For brain, liver and spleen, RNA pellets were resuspended in water, adjusted to 20 mM Tris-HCl *p*H 7.5, 1 mM EDTA, 0.5 M LiCl, 0.2% SDS, then passed through an oligo(dT)-cellulose column, washed with similar buffer, and poly(A) RNA was eluted with H_2O. Poly(A) RNA was brought to 0.3 M sodium acetate and precipitated with ethanol at −20 °C as before. RNA was stored at −20 °C as an ethanol precipitate. For analysis of mRNA, 3–6 μg of RNA was pelleted from the ethanol suspension, dried, redissolved in 0.01 M sodium phosphate buffer *p*H 7.4 containing 2 mM EDTA, 50% formamide and 6% formaldehyde, heated at 68 °C for 5 min and fractionated by electrophoresis in 1% agarose in 0.01 M sodium phosphate *p*H 7.4, 6% formaldehyde for 16 h at 20 V. Gels were then blotted onto nitrocellulose in 20× SSPE[26], and baked at 80 °C in a vacuum for 2 h. For hybridization to the oligonucleotide probe, filters were prehybridized in 6× SSPE, 0.1% SDS, 0.002 M sodium pyrophosphate, 100 μg ml^{-1} sheared herring sperm DNA and 1× Denhardt's at 37 °C for 3 h. Oligonucleotides were synthesized on a SAM-1 DNA synthesizer (Biosearch, San Rafael, California). To include all possible nucleotide sequences giving the published PrP27-30 amino-acid sequence, 32 different oligonucleotides were synthesized in a mixture as shown in Table 1; 0.1 μg of the oligonucleotide mixtures was labelled with 0.2 mCi of [γ-^{32}P]ATP in 100 mM Tris-HCl *p*H 7.5, 10 mM $MgCl_2$, 10 mM DTT using two units of polynucleotide kinase for 1 h at 37 °C. Non-bound radioactivity was removed by binding the oligonucleotides to a DE52 column in 0.1 M NaCl in TE (10 mM Tris-HCl *p*H 7.5, 1 mM EDTA), and eluting with 1.0 M NaCl in TE. The prehybridized filter was rinsed in 6× SSPE, 0.1% SDS, 0.002 M sodium pyrophosphate and the ^{32}P-labelled oligonucleotide was allowed to hybridize to the filter in this buffer at a concentration of 2×10^6 d.p.m. ml^{-1} at 37 °C for 18 h. Filters were then washed repeatedly in hybridization buffer without probe at 42 °C, and were exposed to film at −70 °C using a Lightning-Plus intensifying screen.

R = A or G; Y = C or T (or U); N = any base. mRNA from scrapie-infected mouse brain was used to synthesize cDNA using the conditions of Okayama and Berg[22] with an oligo(dT) primer. Reverse transcriptase was obtained from Seikagaku America, Inc., St Petersburg, Florida. mRNA:cDNA duplexes were extracted with phenol-chloroform, precipitated with ethanol, and the second DNA strand synthesized using the method of Gubler and Hoffman[23]. After extraction and precipitation as above, *Eco*RI sites were methylated with *Eco*RI methylase and DNA ends filled-in with the Klenow fragment of DNA polymerase. DNA was extracted and precipitated again and was ligated to *Eco*RI 8-mer linkers (New England BioLabs) using T4 DNA ligase. After 18 h at 12 °C, the reaction tubes were heated to 70 °C for 5 min to inactivate the ligase and linkers were digested for 4 h at 37 °C with *Eco*RI (12 units per μg cDNA). Small DNA fragments were removed by microdialysis for 1 h on Millipore VM 0.05-μm filters against *Eco*RI digestion buffer. *Eco*RI was again added for a second cycle of digestion, followed by microdialysis. DNA was then extracted, ethanol-precipitated and ligated to *Eco*RI-digested calf alkaline phosphatase-digested (Boehringer-Mannheim) λgt 11 DNA[24]. The ligation mixture was packaged using the Packagene system (Promega-Biotec, Madison, Wisconsin) and used to infect *Escherichia coli* strain Y1088 (ref. 25). Plaques were screened by blotting onto nitrocellulose filters[26] and were probed with ^{32}P-labelled oligonucleotide (see Fig. 1 legend). A positive plaque was picked off and purified by re-plating twice; DNA was isolated, digested with *Eco*RI and two insert fragments of 0.9 and 0.8 kb were found. The oligonucleotide hybridized only to the larger fragment. Both fragments were isolated on 1% low-melting point agarose (Sea Plaque; FMC Corp., Rockland, Maine), purified on Elutip ion-exchange columns (Schleicher & Schuell) and subcloned into M13 (mp18)[27] (BRL) and pEMBL8 (ref. 28). Complementary clones containing both the 0.8- and 0.9-kb fragments were identified by the C test[27], and the partial DNA sequence was determined using the dideoxy method[29]. The 0.8-kb fragment, which did not hybridize with the oligonucleotide, had a 60–70-base poly(dT) region at the junction with the M13 vector (sequence not shown), indicating that this DNA fragment was copied from the poly(A)-containing 3′ end of the mRNA. The 0.9-kb fragment, which hybridized with the oligonucleotide probe, had no poly(dT) sequence at either end, indicating that this fragment was derived from the 5′ end of the mRNA. The preliminary DNA sequence of one end of this fragment is shown. The amino-acid translation of this sequence shows exact homology with the published 15-amino-acid sequence of PrP27–30 (boxed). There is an open reading frame which continues as far as the sequence was read (237 bases from the *Eco*RI site of linkage to the M13 vector).

Messenger RNA populations were obtained from brains, livers and spleens of scrapie-infected mice or hamsters. The oligonucleotides hybridized with 1–3 bands in 9 of 15 samples analysed; however, in no case was there evidence for a scrapie-specific mRNA species (Fig. 1). In each case, uninfected cells or organs showed a band(s) similar to that seen in infected cells. The bands exhibited some 'organ specificity' as both hamster and mouse brain and mouse neuroblastoma cells showed a prominent 2.4–2.5-kb band which was not seen in mouse spleen. There was a weaker reaction with a similar-sized band in mouse and hamster liver. After longer exposure of the autoradiographs, a second band (1.3 kb) was seen in mouse liver and two other bands (2.0 and 1.2 kb) were seen in mouse neuroblastoma cells. However, when the blots were washed at higher temperatures (48 °C), most of these bands disappeared and only the 2.5-kb bands seen in the brain and neuroblastoma cells remained (data not shown).

In the hybridization conditions used, the oligonucleotides may have hybridized to mRNAs having rather poor homology. If a cDNA clone of the message for the PrP27–30 could be isolated, a more precise analysis should be obtained. Therefore, we used the oligonucleotides to screen a cDNA library made from scrapie-infected mouse brain. One clone was isolated, and its partial DNA sequence indicated that it could be translated into an animo-acid sequence identical to PrP27–30 at all 15 positions known (Table 1). Thus, this clone seemed to contain a sequence corresponding to the PrP27–30 protein message. Comparison of the predicted amino-acid sequence shown in Table 1 with a computer bank of known sequences has revealed to date no close homology with any protein tested, except PrP27–30. When the clone was used as a probe against various mRNAs, a prominent 2.4–2.5-kb band was seen in both normal and scrapie-infected mouse and hamster brain (Fig. 2); there was no evidence for any unique mRNA associated with scrapie infection. Furthermore, there was no reactivity with any mRNA in mouse spleen, which is known to contain significant infectivity[18–20]. Liver mRNA also failed to hybridize with the cDNA clone, indicating that PrP27–30 was not synthesized in this organ and reactivity of liver mRNA with the oligonucleotide probably detected a message unrelated to PrP27–30.

These results suggest that the published PrP27–30 sequence may not be specific for the infectious scrapie agent; our data imply that a similar protein exists in uninfected mouse and hamster brain. However, if expression of this protein is associated with scrapie disease[12], post-transcriptional regulation could conceivably result in increased levels of the protein in infected brain tissues. It is also possible that the messages detected in normal and infected tissues encode proteins which differ by point mutations or post-translational modifications; this might result in important biological variations similar to those encountered with certain cellular *onc* genes[21]. If this were the case, the normal homologue of the scrapie gene sequence would be endogenous in normal brains. It is interesting to note that PrP27–30 of mouse and hamster must be highly homologous as the hamster PrP27–30 protein sequence was identical to the translated sequence derived from mouse brain cDNA.

Another, to us more likely, interpretation of these results is that PrP27–30 is a normal protein of both mouse and hamster brain which is apparently synthesized in neurones such as the neuroblastoma cell line tested. This protein may be a component

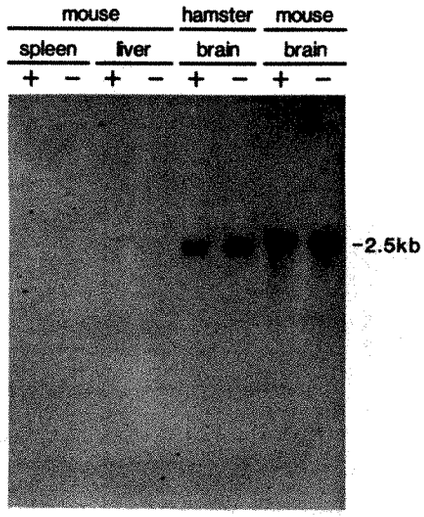

Fig. 2 Hybridization of the PrP27-30 cDNA clone with various mRNAs from hamster and mouse. Poly(A) RNA from various organs was electrophoresed in a formaldehyde agarose gel, blotted onto nitrocellulose, baked for 2 h *in vacuo*, then prehybridized in 2× SSPE, 0.1% SDS, 5× Denhardt's, 50 μg ml^{-1} denatured salmon sperm DNA at 65 °C for 3 h. Hybridization to the nick-translated (specific activity 5×10^7 d.p.m. μg^{-1}) 0.9-kb cDNA clone in the pEMBL8 vector was done in similar conditions for 40 h. Blots were washed three times for 30 min with 2× SSPE, 0.1% SDS and once with 0.1× SSPE, 0.1% SDS at 65 °C, and were exposed to film. +, Scrapie-infected; −, uninfected. When blots previously hybridized to the oligonucleotides (Fig. 1) were eluted and rehybridized to the cDNA clone, the bands detected migrated in an identical manner to the 2.4-2.5-kb bands detected by the oligonucleotides in mouse and hamster brain and neuroblastoma cell RNA; mouse and hamster liver and spleen RNA on these blots showed no hybridization with the cDNA probe (data not shown).

of the scrapie-associated fibrils which appear to be a consistent pathological feature of scrapie infection and disease; in this case, PrP27-30 would be concentrated during the isolation procedures used to purify the fibrils and the associated scrapie infectivity. It remains to be seen whether this protein has an active or passive role in the pathogenicity of scrapie infection.

We thank Gary Hettrick and Robert Evans for graphics assistance, and Helen Blahnik for preparing the manuscript.

Note added in proof: Since submission of this manuscript we have become aware of results by Oesch *et al.* (*Cell*, in the press) concerning cloning of PrP27-30-specific cDNA from scrapie-infected hamster brain. The DNA sequence of this hamster clone, kindly provided by Dr S. Prusiner, shows 84% base homology with the mouse cDNA sequence given in Table 1.

Production of a monoclonal antibody to and molecular characterization of B-cell stimulatory factor-1

Junichi Ohara & William E. Paul

Laboratory of Immunology, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, Maryland 20205, USA

B-cell stimulatory factor-1 (BSF-1)[1], formerly designated B-cell growth factor, is a T-cell-derived factor required for entry into the S phase of the cell cycle by B cells stimulated with low concentrations of anti-IgM antibodies[2-5]. BSF-1 acts directly on resting B cells to prepare them to synthesize DNA more promptly on subsequent exposure to competent stimuli[6,7] and to strikingly enhance their expression of class II molecules of the major histocompatibility complex[8,9]. Previous studies have shown that murine BSF-1 can be separated physically from interleukin-2 (IL-2) and that the molecule has an apparent relative molecular mass (M_r) of ~15,000 and *p*I values of 6.4–6.7 and 7.4 (ref. 10). Here, we report the production of a monoclonal antibody to BSF-1, its use in characterizing BSF-1, and functional studies demonstrating that this molecule is distinct from IL-1, IL-2 and IL-3.

BSF-1 was obtained from 5-10-l batches of serum-free supernatants of cells of the EL-4 line, a C57BL/6 thymoma, which had been induced with 4β-phorbol 12β-myristate 12α-acetate (10 ng ml^{-1}, Sigma) for 48 h. Partially purified BSF-1 was used to immunize rats, and spleen cells from these animals used to obtain hybridomas (Fig. 1 legend). Subcloning of a selected hybridoma produced two lines, 18F10 and 11B11, both secreting rat IgG1 antibodies, which possessed identical properties and were used interchangeably (Fig. 1 legend).

Figure 1*a* illustrates the absorption assay for BSF-1 and demonstrates that 18F10 binds a major fraction of BSF-1 activity (9 U) when plates are coated with 40 ng of purified monoclonal antibody (Fig. 1*a*). Both 18F10 and 11B11 block BSF-1 activity when added directly to co-stimulation assays (Fig. 1*b*). As little as 8 ng of antibody per 200 μl culture almost completely inhibited the response of resting B cells to Bet-2, a monoclonal rat anti-mouse IgM[11], and 2 U of BSF-1. A rat IgG antibody to

Table 1 Binding to and elution from anti-BSF-1 affinity column

	Volume (ml)	BSF-1 activity U ml^{-1}	Total
Applied sample (TMS-CpG fraction)	5	5,700	28,500
Effluent	5	49	245
Acetic acid (0.8 M) eluate	0.4	74,000	29,600

A 5-ml sample of TMS-CpG-fractionated EL-4 supernatant was applied to an affinity column (2 ml packed volume). The effluent (5 ml) was collected and the column was washed with 20 ml of NaCl (1 M), 20 ml NP40 (0.5%) in water, 20 ml phosphate-buffered saline and 20 ml water. The column was then eluted with 20 ml of 0.8 M acetic acid. The eluate was lyophilized and reconstituted with 0.4 ml water. BSF-1 activity was measured in the anti-IgM co-stimulation assay using Bet-2.

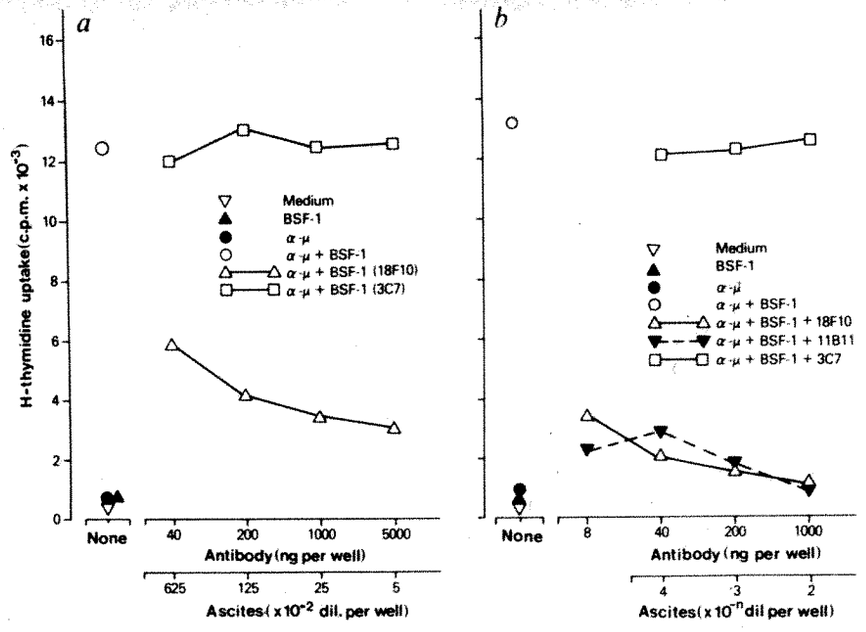

Fig. 1 Monoclonal anti-BSF-1 absorbs BSF-1 (*a*) and inhibits BSF-1 activity (*b*).
Methods. Partial purification of BSF-1, to be described in detail elsewhere (J.O. *et al.*, in preparation), involved adsorption to and elution from trimethyl silyl(TMS)-derivatized controlled pore glass beads (TMS-CpG; Sepralyte; Analytical Chemicals, Harbor City, California) followed by reverse-phase HPLC. This yielded a >2,000-fold increase in specific activity as measured in units (U) defined by the amount of BSF-1 required for half-maximal responses in the anti-IgM co-stimulation assay, using resting B cells as a test population[2]. Lew/Sn rats were immunized with 1.4×10^6 U of TMS-CpG-purified BSF-1 emulsified in complete Freund's adjuvant. Animals were boosted twice with 1.6×10^5 U of HPLC-purified BSF-1 in incomplete Freund's adjuvant, and challenged intravenously with 3.6×10^6 U of HPLC-purified BSF-1. Three days later, spleen cells were fused with the P3-NS-1/1-Ag4-1 line of the P3-X63-Ag8 myeloma. Hybridoma supernatants were screened for anti-BSF-1 activity by an absorption technique in which 24-well culture dishes were coated with ion-exchange chromatography-purified rabbit anti-rat immunoglobulin. Coated culture dishes were incubated with hybridoma supernatants for 4 h, washed and then incubated with a standard amount of HPLC-purified BSF-1 for an additional 4 h. BSF-1 activity remaining in solution was assessed by culturing samples with resting splenic B cells from BALB/c mice in the presence of purified goat anti-mouse IgM (5 μg ml^{-1}) or Bet-2. Uptake of ^{3}H-thymidine was measured after 3 days of culture. Of 72 fusion wells with growing hybridomas, 6 were selected for further study on the basis of this assay. Of these, cells from one fusion well which had reproducible absorptive activity at a high dilution were used in the remaining experiments. The cells from this well were subjected to a series of subclonings, the last of which yielded 18F10 and 11B11, both secreting rat IgG1 antibodies. ***a***, Absorption of BSF-1 activity. Tissue culture wells (Cluster 24, Costar) were incubated with 10 μg of purified rabbit anti-rat immunoglobulin, washed and incubated with various concentrations of purified 18F10 (anti-BSF-1) or with various dilutions of ascitic fluid containing 3C7 (anti-IL-2 receptor). After washing, HPLC-purified BSF-1 (9 U) was added to wells, allowed to incubate for 4 h and supernatants were tested for residual BSF-1 activity in the anti-IgM (α-μ) co-stimulator assay. Bet-2, a monoclonal α-μ, was incubated with purified B cells (1×10^5 per 0.2 ml) in the presence of absorbed supernatants and uptake of ^{3}H-thymidine measured 3 days later. As controls, ^{3}H-thymidine uptake with medium alone, α-μ, BSF-1, or α-μ and BSF-1 are shown. ***b***, Inhibition of BSF-1 activity. Purified B cells were incubated with Bet-2 and BSF-1 (2 U) in the presence of various amounts of purified 18F10 or 11B11 (anti-BSF-1) or of various dilutions of ascitic fluid containing 3C7 (anti-IL-2 receptor). Uptake of ^{3}H-thymidine was measured 3 days later.

Table 2 Anti-BSF-1 does not block responses to IL-1, IL-2 or IL-3

Response of B cells to anti-IgM and BSF-1					
Stimulant	0	11B11		3C7	
		10^{-3}	10^{-4}	10^{-3}	10^{-4}
None	425	497	403	296	176

Response of DA-1 cells to IL-3*					
		0	11B11	50C1	
None		40	—	—	
WEHI-3 supernatant (1:5)		22,073	29,590	21,686	

^{3}H-thymidine uptake in response to anti-IgM and BSF-1 (10 U ml^{-1}) was measured at 3 days of culture and responses to IL-1, IL-2 and IL-3 were measured at 2 days of culture and recorded here as c.p.m. Assays were performed as described in ref. 14 for IL-1, ref. 15 for IL-2 and ref. 16 for IL-3, except that in the last case the concentration of the fetal calf serum (FCS) was 2% rather than 10%. 18F10 and 11B11 are rat monoclonal antibodies to BSF-1; 3C7 is a rat monoclonal antibody to the IL-2 receptor; 50C1 is a rat monoclonal anti-dinitrophenyl antibody; 10^{-3} and 10^{-4} refer to dilutions of ascitic fluid. 3C7 inhibits the proliferation of thymocytes in response to phytohaemagglutinin (PHA) and IL-1 because of the involvement of IL-2 in that response; it also inhibits the proliferation of HT-2 cells in response to IL-2, as the IL-2 receptor is critical to such proliferation.
* Ascitic fluid dilution of 10^{-2} used in these experiments.

the IL-2 receptor (3C7, generously provided by Drs G. Ortega, E. Shevach and T. Malek[12]) had no inhibitory activity, indicating that the response of resting B cells to anti-IgM and BSF-1 does not depend on IL-2, and providing a control for nonspecific inhibition.

To characterize BSF-1 more fully, 1.2×10^5 U HPLC-purified BSF-1 was labelled with ^{125}I by the chloramine-T method. A sample of this material was incubated with affinity-purified monoclonal antibody and immunoprecipitated with Sepharose beads to which rabbit anti-rat immunoglobulin had been coupled. SDS-polyacrylamide gel electrophoresis (PAGE) of dissolved immunoprecipitates yielded two major bands which migrated with apparent molecular sizes of 19,000–20,000 and 14,000, respectively (Fig. 2*a*). Two-dimensional gel electrophoresis (isoelectric focusing followed by SDS-PAGE)[13] indicated that the 19,000–20,000-M_r species had a *p*I of 6.7; the material of lower M_r was not detected on the two-dimensional gel (Fig. 2*b*). The *p*H range examined was 4.6–7.1 and it is possible that the 14,000-M_r molecule had a *p*I outside this range and migrated off the gel.

HPLC-purified BSF-1 was subjected to SDS-PAGE, then individual lanes were transferred to nitrocellulose paper for protein blotting[14] or cut into fragments for extraction and assay of BSF-1 activity (Fig. 3). ^{125}I-labelled antibody bound to two bands, migrating with mobilities of 19,000–20,000 and 14,000, respectively. Analysis of extracted material showed that the bulk of the BSF-1 activity co-migrated with the 19,000–20,000-M_r species.

The antibody could also be used for purification of BSF-1 from complex mixtures (Table 1). An affinity column was prepared by conjugating a mixture of 18F10 and 11B11 to CnBr-activated Sepharose 4B (1–2 mg antibody per g Sepharose). TMS-CpG-purified EL-4 supernatant (2.85×10^4 U BSF-1) was applied to a 2.0-ml column; 200 U appeared in the effluent and

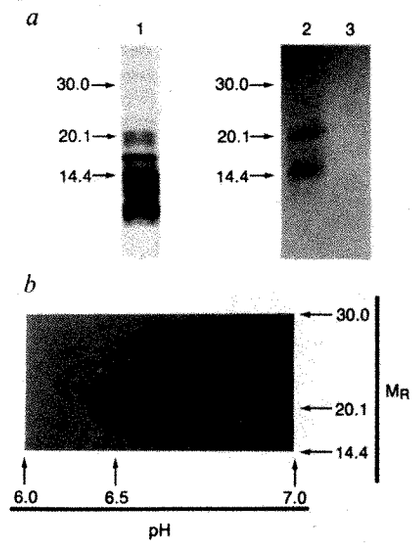

Fig. 2 SDS-PAGE (*a*) and two-dimensional gel electrophoresis (*b*) of immunoprecipitates of HPLC-purified ^{125}I-labelled BSF-1. *a*, SDS-PAGE of HPLC-purified ^{125}I-BSF-1 and of immunoprecipitates prepared with anti-BSF-1 or with normal rat serum. Samples were electrophoresed in 20% polyacrylamide at a constant voltage of 150 V. Autoradiographs were prepared using an intensifying screen and Kodak X-Omat film. Lane 1, SDS-PAGE of HPLC-purified ^{125}I-BSF-1. Lane 2, SDS-PAGE of a sample prepared by overnight incubation of HPLC-purified ^{125}I-BSF-1 with affinity-purified 18F10 and 11B11 (100 μg), absorption with Sepharose 4B, and then binding to rabbit anti-rat immunoglobulin coupled to Sepharose 4B. The sample was dissolved by boiling in 0.1% SDS in 2 mM dithiothreitol, 1 mM EDTA. Lane 3, SDS-PAGE of a sample prepared identically to that in lane 2 except that normal rat serum (10 μl) was used in place of 18F10 and 11B11. *b*, Two-dimensional electrophoresis of a replicate sample of the immunoprecipitate applied to lane 2 of the SDS-PAGE in *a*. The dissolved sample was placed in a buffer containing 9.5 M urea, 2% NP40, 2% ampholines (1.6%, *p*H 5–7; 0.4%, *p*H 3–10), and 5% β-mercaptoethanol in water and applied to an electrofocusing gel. After focusing, the sample was subjected to SDS-PAGE. The *p*H range analysed was 4.6–7.1. Only a portion of the autoradiograph is illustrated here. M_r values given are $\times 10^{-3}$.

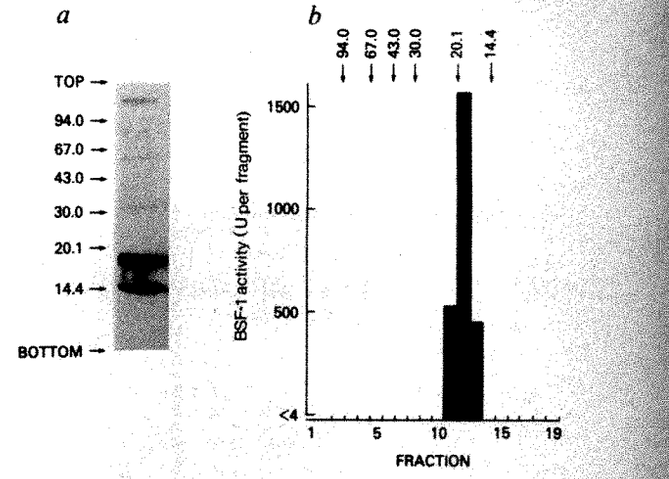

Fig. 3 Protein blotting (*a*) and BSF-1 activity of HPLC-purified BSF-1 separated on SDS-PAGE (*b*). *a*, 2.8×10^4 U of HPLC-purified BSF-1 in 20 μl was separated by SDS-PAGE as in Fig. 2*a*. Low-M_r markers ($\times 10^{-3}$; Pharmacia) were included in these lanes and in parallel lanes. The contents of this lane were transferred to nitrocellulose paper, using a Transblot Cell (Bio-Rad) and developed with ^{125}I-labelled 11B11. *b*, 2.8×10^4 U of HPLC-purified BSF-1 in 20 μl was separated by SDS-PAGE. The lane was cut into 0.5-cm fragments which were disrupted in 20% FCS-containing medium by cycles of freezing and thawing; extracted material was assayed for BSF-1 activity and is shown in units per fragment. Low-M_r markers were included in the separated sample and in adjacent lanes; the latter were stained with Coomassie blue to determine the location of each marker.

elution with 0.8 M acetic acid yielded 2.96×10^4 U. When BSF-1 was applied to a control column, prepared by conjugating normal rat immunoglobulin to Sepharose 4B, essentially all applied BSF-1 activity appeared in the effluent.

The antibody has also been used to test the relationship of BSF-1 to several other well-defined lymphokines. Table 2 indicates that although 18F10 ascites at a dilution of 10^{-4} causes marked inhibition of BSF-1 activity, the activities of IL-1, IL-2 and IL-3 tested, respectively, in a thymocyte assay[15], on the growth of HT-2 cells[16] and in the stimulation of an IL-3-dependent T-cell line, DA-1 (ref. 17), are not inhibited even at dilutions of ascitic fluid of 10^{-2}.

We found a discrepancy in the apparent size of the active BSF-1. Previous studies, based on separation of EL-4 supernatants by phenyl Sepharose chromatography and characterization on SDS-PAGE, had indicated respective M_rs for BSF-1 of 15,000–16,000 and 11,000 (ref. 10). The present results indicate that two major molecular species bear an antigenic determinant that reacts with the monoclonal anti-BSF-1 antibody. The larger, 19,000–20,000-M_r species, has BSF-1 activity, whereas the activity of the smaller species remains unresolved. The BSF-1 used in the present studies was prepared from the same cell line used in the previous work, the antibody seems to bind to virtually all material possessing BSF-1 activity in EL-4 supernatant, and the co-stimulation assay used is essentially identical. Gel filtration studies of a human BSF-1-like molecule have revealed a M_r of 17,000 which fell to 14,000 on treatment with 4 M urea[3], raising the possibility that changes in apparent M_r result from the nature of the purification procedure used. Nonetheless, the relationship between the active 19,000–20,000-M_r species and the 14,000-M_r species remains to be established.

Results indicating that BSF-1 is distinct from IL-1, IL-2 and IL-3 confirm earlier but less direct work[2–5,10]. This, together with the absence of interferon activity in BSF-1 preparations, indicates that BSF-1 is unique.

Thus, our results demonstrate the value of the monoclonal antibody to BSF-1 as a tool for the molecular characterization and purification of this lymphokine. Indeed, it had previously been proposed that this stimulant be designated BSF-p1, the 'p' reflecting the provisional assignment of the designation in view of the still-partial characterization of the molecule[1]. The development of a monoclonal antibody and our more precise characterization now allows us to refer to this as BSF-1.

The finding that the monoclonal antibody is a powerful inhibitor of BSF-1 activity in the anti-IgM co-stimulation assay may allow the role of BSF-1 to be examined in a wide variety of *in vitro* and *in vivo* immune responses, by incorporating the antibody in culture or by treating animals with anti-BSF-1. Such studies are now in progress.

We thank Drs Thomas Malek, Susumu Nishinarita, John Kung, Fred Finkelman, Julian Ambrus, Gustavo Ortega, Ethan Shevach, Lennart Logdberg and Mitsuo Honda for advice and assistance at various stages of this work. The preparation of supernatants of EL-4 cells by Dr D. R. Jaganath of Litton Bionetics is gratefully acknowledged, as is the technical assistance of Stephanie Lahet, Cynthia Watson and Patricia Korty and the editorial assistance of Shirley Starnes. We thank the Kroc Foundation for partial support of this project.

Anti-idiotypic T cells suppress rejection of renal allografts in rats

F. Lancaster, Y. L. Chui & J. R. Batchelor

Department of Immunology, Royal Postgraduate Medical School, Hammersmith Hospital, Du Cane Road, London W12 0HS, UK

Kidney allografts between inbred rats differing at the major histocompatibility complex (MHC) are normally rejected, usually within 10 to 12 days. In many strain combinations, however, permanent graft acceptance can be induced by either immunological enhancement[1,2] or a short course of immunosuppressive chemotherapy[3–5]. In both cases, prolonged graft survival is accompanied by the appearance in the spleen of a population of suppressor cells[6]. When transferred to a syngeneic host, these cells abrogate or strikingly diminish the rejection response elicited by a renal allograft of the same genotype as the original kidney donor. We have now examined the properties of these suppressor cells and have detected a subpopulation that proliferates *in vitro* when stimulated by irradiated syngeneic T blasts reactive to MHC alloantigens of the kidney donor strain. Comparable proliferation, however, is not induced either by syngeneic blasts reactive to a third strain or by polyclonal syngeneic blasts. These results support the hypothesis that this subpopulation is anti-idiotypic, with specificity for the idiotypes carried by syngeneic T cells stimulated by the kidney allograft. Such anti-idiotypic cells could function as suppressors.

Long-lived immunologically enhanced kidney allografts were induced as follows: AS ($RT1^l$) recipient rats were given 50×10^6 donor strain spleen cells intravenously 12 days before transplantation, together with three injections of AS anti-donor antiserum on days −11, 0 and +1. This procedure induces donor-specific hyporesponsiveness in the AS recipient, enabling it to accept a semi-allogeneic $(AS \times AUG)F_1$ kidney graft, and subsequently a fully allogeneic homozygous AUG graft that survives and functions indefinitely. At least two mechanisms seem to be involved in long-term allograft survival. First, the strong immunogenicity characteristic of a primary MHC-incompatible graft is reduced as donor strain dendritic cells are lost from the grafted tissue[7] and second, the graft recipient progressively develops increasing hyporesponsiveness to the donor genotype, which can be adoptively transferred in a population of splenic T lymphocytes[8].

Long-term kidney allograft survival can also be induced with the use of immunosuppressive drugs, of which cyclosporin is one of the most effective currently available[3–5]. In the rabbit, and in many rat strain combinations, indefinite graft acceptance can be achieved following a limited course of drug treatment for 2–4 weeks[4,6,9]. Recent evidence suggests that long-term graft survival after pharmacological immunosuppression may depend on similar mechanisms to those responsible for the maintenance stage of immunological enhancement[6]. Similar mechanisms may also apply in clinical organ transplantation, because patients show diminishing requirements for immunosuppression during the later post-transplant period. Consequently, the properties of such putative suppressor cells, in particular their specificity, are of considerable interest.

The experimental protocol to investigate cell specificity *in vitro* is shown in Fig. 1. Strain AS ($RT1^l$) rats carrying accepted $(AS \times AUG)F_1$ or AUG ($RT1^c$) kidneys (immunological enhancement), or AUG or WAG ($RT1^u$) kidneys (pharmacological immunosuppression) were boosted with 10×10^6 spleen cells of kidney donor genotype on day −6 to maximize the number of suppressor cells present in the spleen. On day 0, the spleens of these animals were excised, and cell suspensions prepared in culture medium (RPMI 1640 supplemented with 2mM L-glutamine, 100 units penicillin and streptomycin per ml, 5% heat-inactivated fetal calf serum v/v). These spleen cells, at 2×10^6 viable lymphocytes per ml, formed the responder population for mixed leukocyte cultures.

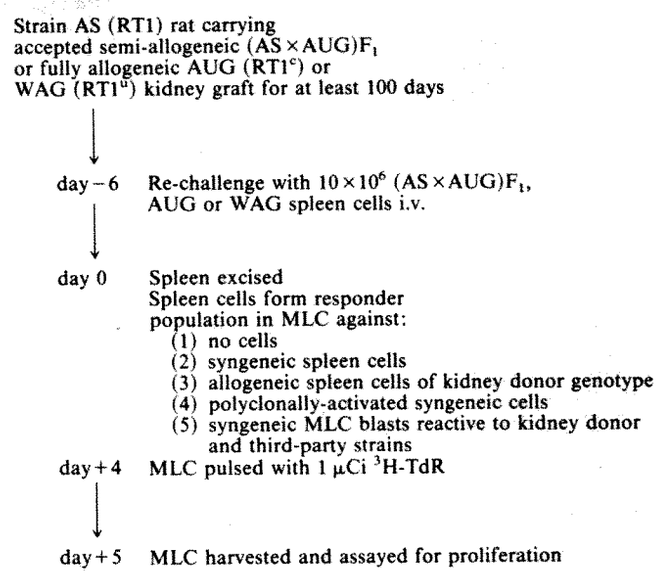

Fig. 1 Model of *in vitro* culture system.

Stimulator cells were prepared as follows. Activated blasts of the same strain as the graft recipient (AS, $RT1^l$) were generated *in vitro* by polyclonal activation or in mixed leukocyte culture (MLC). Polyclonal blasts were collected 3 days after stimulation with concanavalin A (Con A, 1 $\mu g\ ml^{-1}$), whereas blasts generated in MLC against either the kidney donor strain (AUG or WAG) or against an unrelated third party strain were restimulated (2^0 MLC) with the same antigen on day 10 of culture, and were harvested 3 days later. Normal spleen cells of both recipient and donor strains were also prepared. Activated blasts and normal cell suspensions were X-irradiated (3,000 rad) before use.

Responder (R) and stimulator (S) populations were then mixed at R:S of 1:1 in the presence of 2-mercaptoethanol (2-ME, 5×10^{-5} M), and were maintained *in vitro* for 5 days (optimal time-course determined from previous experiments, data not shown). The cells were pulsed with ^{3}H-TdR 1 $\mu Ci\ ml^{-1}$ for the final 18 h of culture.

Results of cell proliferation in response to the different stimulating populations are presented in Tables 1 and 2. Essentially similar results were obtained using spleen cells from animals with long-surviving kidney allografts irrespective of the method used to ensure protection of the graft. Table 1 presents spleen cell responses of rats with enhanced grafts and Table 2 those of rats that had received immunosuppression consisting of cyclosporin (10 mg per kg per day by gavage for 14 days post-transplant). In each case, spleen cells from animals with long-surviving kidney allografts showed a diminished response to stimulator cells of kidney donor genotype when compared to spleen cells from naive control animals. However, they demonstrated marked proliferation in response to syngeneic 2^0 MLC blasts reactive to the kidney donor strain. Significantly, this proliferative response was not elicited by polyclonal syngeneic blasts, or by 2^0 MLC blasts reactive to a third party strain, indicating that cells from the kidney graft recipient were not

Table 1 Proliferative responses of spleen cells from individual AS ($RT1^l$) rats carrying long-surviving immunologically enhanced (AS×AUG)F_1 or homozygous AUG ($RT1^c$) kidneys

Source of responder cells	Expt	Stimulator cells: No cells	Normal AS spleen	Normal AUG spleen	Con A-stimd AS blasts	AS blasts generated in 2° MLC, reactive to: AUG	WAG	DA

	8	0.8±0.2	0.8±0.3	7.4±0.6	6.8±1.1	—	2.9±0.7	3.0±0.4	1.7±0.1

Values represent proliferative activity in MLC (c.p.m.±s.e.×10^{-3}). Responder and stimulator cell preparation as described in the text. Culture volumes were 200 μl, with six replicates per culture.

merely being nonspecifically stimulated by activated syngeneic cells. The slight increase in ^{3}H-TdR uptake by responder cells in the presence of these non-specific stimulators may possibly be attributed to secretion of interleukins by activated stimulator cells.

These data suggest that a population of T lymphocytes contained within the spleens of rats bearing accepted renal allografts can specifically recognize and respond to the idiotypic determinants present on syngeneic cells reactive to the kidney donor genotype. Other explanations, for example a response against retroviruses carried by syngeneic blasts, are unlikely in view of the specificity of the response. Likewise the notion that the spleen cells from AS rats with long-surviving AUG kidneys proliferate in response to highly immunogenic alloantigen presented by or adsorbed to the surface of the AS anti AUG blasts seems improbable in view of the negligible response of naive AS spleen cells to such blasts. Further, there is a marked diminution in responsiveness of spleen cells from the 'suppressed' AS rats when cultured with AUG stimulator cells. Although not proven at the clonal level, this anti-idiotypic subpopulation is a strong candidate for the cell which mediates suppression of kidney allograft rejection *in vivo*.

Suppression of skin-graft rejection induced by autoimmunization with MLC blasts and attributed to anti-idiotype responses was reported by Andersson *et al.*[10]; however, it has proved difficult to confirm their experiments, which were based on a concept of shared idiotypes between T and B lymphocytes—an idea still unproven in the context of responses to MHC alloantigens. Dorsch and Roser[11], Stockinger[12], and Stephenson and Roser[13] have presented evidence that neonatally induced tolerance is mediated by suppressor cells with anti-idiotypic specificity, and Kimura and Wilson[14] have similarly concluded that resistance to graft-versus-host disease induced in F_1 rats injected with sublethal numbers of parental lymphocytes is due to anti-T cell idiotype responses. Our experiments show that a population of cells capable of transferring suppression powerful enough to protect a homozygous MHC incompatible kidney graft from rejection also contains a subpopulation of T cells which have anti-idiotypic specificity *in vitro* for syngeneic clones directed against the MHC antigens of the graft. Taken together, this evidence suggests that anti-T cell idiotype responses may underlie many states of unresponsiveness to MHC incompatible tissues, and it raises the question as to whether the same mechanisms are involved in self tolerance.

We thank Ms B. E. Phillips for technical assistance. This research was supported by the MRC and the National Kidney Research Fund.

Developmental regulation of a cloned adult β-globin gene in transgenic mice

Jeanne Magram, Kiran Chada & Frank Costantini

Department of Human Genetics and Development,
College of Physicians and Surgeons of Columbia University,
701 W. 168th Street, New York, New York 10032, USA

At different stages of mammalian development, distinct embryonic, fetal and adult haemoglobins are synthesized in erythroid cells, a process termed haemoglobin switching. The cellular and molecular mechanisms controlling haemoglobin switching have been intensively studied, but remain poorly understood[1]. To study the developmental regulation of globin gene expression, we have produced transgenic mice[2–6] in which cloned globin genes are present in erythroid cells throughout development. Recently, we reported that adult mice in several transgenic lines carrying a hybrid mouse/human adult β-globin gene, expressed the gene in a correct tissue-specific manner[7]. This finding raised the question of whether an exogenous globin gene could also be subject to appropriate stage-specific regulation. We report here that the hybrid β-globin gene, like the endogenous adult β-globin genes, is inactive in yolk sac-derived embryonic erythroid cells and is expressed for the first time in fetal liver erythroid cells. Our results indicate that a stage-specific pattern of expression can be conferred by *cis*-acting regulatory elements closely linked to an adult β-globin gene. They also suggest that the embryonic and adult β-globin genes in the mouse are activated (or repressed) by distinct *trans*-acting regulatory factors present in embryonic, fetal and adult erythroid cells.

The timing of expression of the various β-like globin genes during normal mouse development has been well characterized. The first erythroid cells are produced in the blood islands of the yolk sac between days 7 and 11 of gestation, and are released into the embryonic circulation where they persist until day 15–16 (refs 8, 9). Before day 12, these 'primitive' nucleated erythrocytes synthesize the embryonic β-like globin chains y and z[10–12], encoded by two genes termed *y* and *βh1* (refs 13, 14); at around day 12, the primitive erythrocytes begin to produce small quantities of the adult β-globin chains[15,16] in addition to the y and z chains. The next site of erythropoiesis is the fetal liver, from which smaller, non-nucleated erythrocytes are released, beginning at ~day 12 and continuing until birth[17–19]. In fetal liver erythroid cells, all of the β-like globin chains are encoded by the adult β-globin genes, and the *y* and *βh1* genes are inactive[9–11]. At about day 16, erythropoiesis begins in the spleen and bone marrow, where it continues after birth[8]. The 'adult' erythroid cells produced in these organs display a pattern of globin gene expression similar to that observed in the fetal liver erythroid cells[9–11]; thus, the mouse has no separate 'fetal' globin

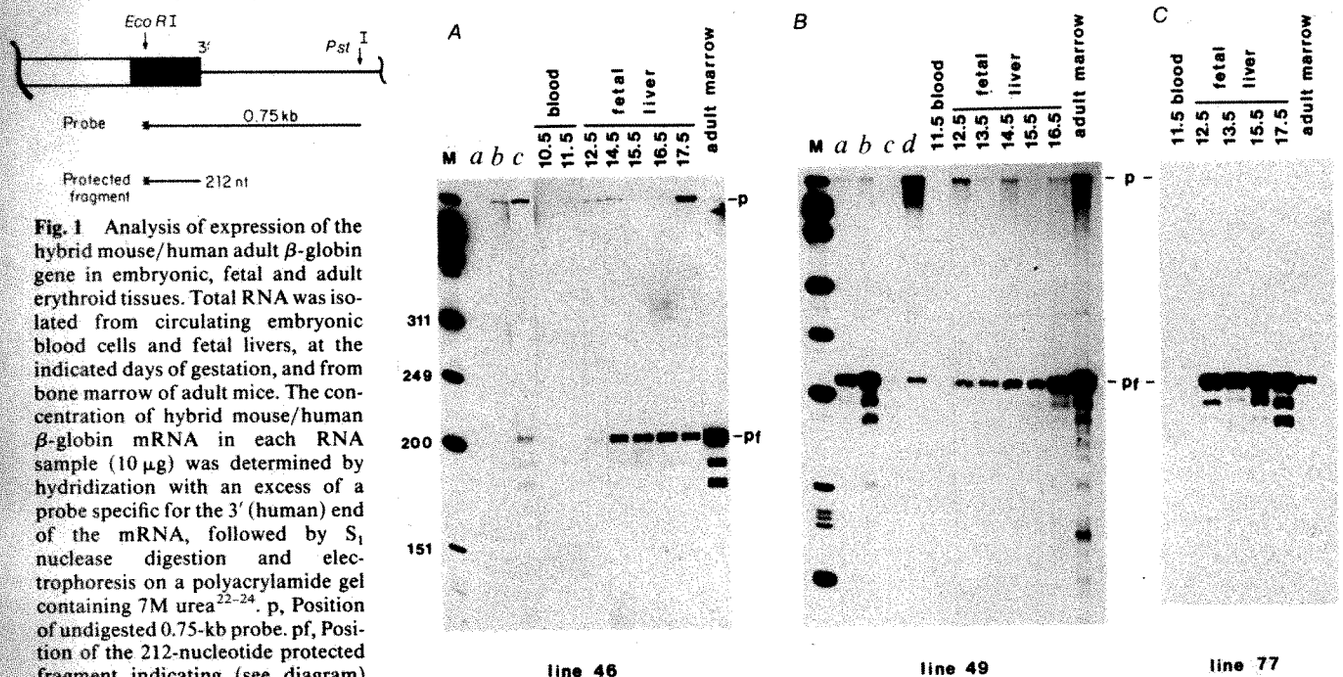

Fig. 1 Analysis of expression of the hybrid mouse/human adult β-globin gene in embryonic, fetal and adult erythroid tissues. Total RNA was isolated from circulating embryonic blood cells and fetal livers, at the indicated days of gestation, and from bone marrow of adult mice. The concentration of hybrid mouse/human β-globin mRNA in each RNA sample (10 μg) was determined by hydridization with an excess of a probe specific for the 3′ (human) end of the mRNA, followed by S_1 nuclease digestion and electrophoresis on a polyacrylamide gel containing 7M urea[22–24]. p, Position of undigested 0.75-kb probe. pf, Position of the 212-nucleotide protected fragment indicating (see diagram) correctly terminated human or hybrid mouse/human β-globin mRNA (the bands of lower relative molecular mass (M_r) were not reproducibly observed and are believed to be S_1 nuclease artefacts). It has previously been shown that the hybrid mRN4 has correct 5′ termini[1]. M, M_r markers (ΦX174 DNA digested with *Hin*fI). *A*, Transgenic mouse line 46: lanes *a–c*, positive control hybridizations with human cord blood RNA samples containing 1.4, 7 and 14 pg, respectively, of β-globin mRNA. *B*, Transgenic mouse line 49: lanes *a–d*, human cord blood RNA containing, respectively, 14, 70, 1.4 and 2.8 pg of β-globin mRNA. *C*, Transgenic mouse line 77. The steady-state level of endogenous β-globin mRNA in both fetal liver and adult bone marrow RNAs, expressed as a fraction of total RNA, is $\sim 10^{-3}$ (Fig. 2 and ref. 7). The approximate steady-state levels of the hybrid β-globin mRNA, determined by comparison with human β-globin mRNA standards, were: line 46 fetal livers (days 14.5–17.5), 3×10^{-6}; line 46 bone marrow, 1.5×10^{-5}; line 49 fetal livers (days 12.5–15.5), 5×10^{-7}; line 49 bone marrow, 10^{-5}; line 77 fetal livers, 2×10^{-5}; line 77 bone marrow, 2×10^{-6}. Lines 46 and 49 each contain one copy of the hybrid gene per diploid genome, while line 77 carries three copies[7].

Methods. Homozygous transgenic males from lines 46 and 49 were mated with normal C57BL/6J females and the resulting hemizygous transgenic embryos were dissected out at various stages of gestation. The day on which the copulation plug was observed was designated day 0. In line 77, which carries the foreign gene on the X chromosome, hemizygous transgenic males were mated with homozygous transgenic females to produce 100% transgenic (hemizygous male or homozygous female) embryos. Embryos in their extraembryonic membranes were first washed in phosphate-buffered saline (PBS) containing 10 U ml^{-1} heparin (PBS/H) to remove maternal blood. The membranes were then removed, the embryos were bled from the umbilical cord into PBS/H, and the cells were collected by centrifugation. Blood cells or whole fetal livers were pooled from 5–10 embryos at the same stage of gestation, and total RNA was isolated by homogenization in 4M guanidine thiocyanate and centrifugation through CsCl[34]. RNA concentrations were determined from the A_{260} and confirmed by electrophoresis on denaturing formaldehyde/agarose gels[35], which also showed that the RNA preparations were undegraded, as judged by the ribosomal RNA profiles. Preparation of the probe, hybridization and S_1 nuclease analysis were performed as described elsewhere[6,7]. The concentration of β-globin mRNA in the human cord blood RNA was determined by R_0t analysis (data not shown) to be 1%, in agreement with published estimates of the globin mRNA content of reticulocytes[36].

genes. This contrasts with the pattern of haemoglobin switching in humans, in which the adult β-globin gene encodes only ~5% of the β-globin chains in fetal liver erythroid cells (the majority being encoded by the fetal ^{A}-γ and ^{G}-γ genes) and becomes maximally active after birth[20].

The transgenic mice used in this study carried between one and three copies of a hybrid mouse/human β-globin gene that included the 5′ portion of the mouse β^{dmaj} adult globin gene and 1.2 kilobases (kb) of 5′ flanking DNA, joined to the 3′ portion of the human β-globin gene and 2 kb of 3′ flanking human DNA[7,21]. All of the plasmid vector DNA, except for 350 base pairs, had been removed from the gene before microinjection into mouse zygotes. Adult mice in four different transgenic lines were found to express the foreign globin gene exclusively or predominantly in erythroid tissues[7]. Here we examine the developmental regulation of the hybrid β-globin gene in three of the lines, numbered 46, 49 and 77.

Circulating blood was collected from transgenic embryos at day 10.5 or 11.5 post-coitum (p.c.), a stage at which essentially all of the blood cells are primitive erythrocytes derived from the yolk sac. Whole livers, consisting largely of fetal erythroblasts, were dissected from 12.5–17.5-day p.c. fetuses. In addition, bone marrow was obtained from the femurs of adult transgenic mice. Total RNA was isolated from each of these tissues, and the level of hybrid mouse/human β-globin messenger RNA was measured by hybridization with a ^{32}P-labelled probe specific for the human portion of the mRNA, followed by digestion with S_1 nuclease, electrophoresis on polyacrylamide gels and autoradiography[21–24].

No hybrid mouse/human β-globin mRNA was detected in blood cell RNA from 10.5- or 11.5-day p.c. embryos, in any of the three transgenic lines examined. In contrast, the foreign mRNA was detected in fetal livers at all stages examined, as well as in the adult bone marrow (Fig. 1). For comparison, the expression of the endogenous adult β-globin genes in the same tissues was monitored by hybridization with a probe specific for mouse adult β-globin mRNA (Fig. 2). As expected, the endogenous adult mRNA was detected only in trace amounts in circulating blood of 11.5-day p.c. or earlier embryos, but was present at a high level in the fetal liver and adult marrow. To ensure that the circulating embryonic blood cells analysed were indeed erythroid cells containing globin mRNA, the RNA preparations were hybridized with a probe specific for the mouse embryonic y-globin mRNA. The y-globin specific probe hybridized strongly with RNA from 11.5- or 12.5-day p.c. embryonic blood, but not with fetal liver RNAs (Fig. 3). We conclude that the mouse/human hybrid β-globin gene in three different transgenic mouse lines is inactive in embryonic blood cells, and is first expressed in the fetal liver erythroblasts. This pattern of switching is identical to that of the endogenous adult β-globin genes.

Several aspects of the regulation of the exogenous globin gene differed significantly from that of the endogenous adult β-globin genes. First, the steady-state level of the hybrid β-globin mRNA did not exceed 2–3% (per gene copy) of the level of endogenous β-globin mRNA (see Fig. 1 legend) in either fetal liver or adult bone marrow cells[7]. Second, when the relative levels of expression of the foreign gene in fetal and adult erythroid tissues were compared, two different patterns were observed, each somewhat different from that of the endogenous adult β-globin genes. The endogenous adult β-globin mRNA was present at approximately equal levels in fetal liver and adult bone marrow RNA preparations, in each of the transgenic mouse lines (Fig. 2). In mice of lines 46 and 49, the hybrid β-globin mRNA was present at a 5–20-fold lower level in 12.5–15.5-day p.c. fetal liver RNA than in adult bone marrow RNA (Fig. 1). This low fetal/adult expression ratio is characteristic of the adult β-globin gene in humans[20], suggesting a possible influence of human β-globin sequences in the hybrid gene. However, in the third transgenic line examined (77), the hybrid β-globin mRNA level was 10-fold higher in fetal liver than in adult bone marrow (Fig. 1), which resembles neither the mouse nor the human pattern.

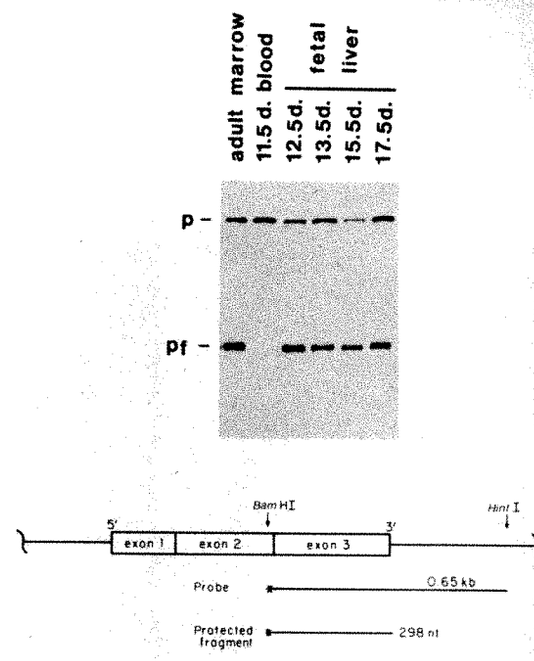

Fig. 2 Analysis of endogenous adult β-globin mRNA in embryonic, fetal and adult erythroid tissues. RNA samples from embryonic blood, fetal liver and adult bone marrow (0.5 μg of each) from transgenic mice in line 77 (the same RNA preparations as analysed in Fig. 1c) were analysed by hybridization with an excess of a probe specific for mouse adult β-globin mRNA, followed by S_1 nuclease digestion and electrophoresis on a polyacrylamide gel containing 7 M urea. The probe was a *Bam*HI–*Hin*fI fragment derived from a mouse β^{dmaj} globin complementary DNA clone[37], and hybridization to either β^{dmaj} globin mRNA or β^{s} globin mRNA (found in C57BL/6J mice) protects a labelled 298-nucleotide (nt) fragment from S_1 nuclease digestion (see diagram). p, Position of undigested 0.65-kb probe; pf, position of 298-nt protected fragment.

Methods. The *Bam*HI–*Hin*fI fragment of a mouse β^{dmaj} globin cDNA clone was 3′ end-labelled with ^{32}P to a specific activity of 6×10^{7} c.p.m. μg^{-1}, strand-separated on a polyacrylamide gel and eluted[24]; 2 ng of the probe was incubated with each mouse RNA sample at 45 °C in 80% formamide buffer[7], then digested with S_1 nuclease[22,23]. Control hybridizations with varying amounts of mouse blood RNA (data not shown) confirmed that the probe was indeed present in excess over the β-globin mRNA, and that the hybridization signals observed (298-nt protected fragment) were proportional to the concentration of mouse β-globin mRNA in each RNA sample.

Similarly, in a fourth transgenic line, 75A (ref. 7), preliminary data (not shown) indicate that the hybrid gene is expressed at a much higher level in the fetal liver than in adult erythroid tissues. We have recently produced several new transgenic mice, carrying either the human β-globin gene or the cloned murine β^{dmaj} globin gene, and analysis of these lines may help to elucidate the factors influencing the fetal/adult expression ratios of the mouse and human adult β-globin genes.

The main conclusion from the data presented here is that an adult β-globin gene, on a 5-kb DNA fragment, contains the information to remain inactive in primitive erythroid cells which are synthesizing embryonic haemoglobins, and yet to be specifically activated later in development in fetal and adult erythroid cells. This represents the first demonstration that a cloned globin gene can be subject to stage-specific regulation during the transition from embryonic to fetal erythropoiesis. It has already been established that globin genes introduced with limited amounts of flanking DNA can be specifically activated during the *in vitro* differentiation of erythroid cell lines[21,25–28] and preferentially expressed in erythroid rather than non-erythroid cells both in tissue culture[29,30] and in transgenic mice[7]. However, the possibility that globin gene switching requires much more DNA

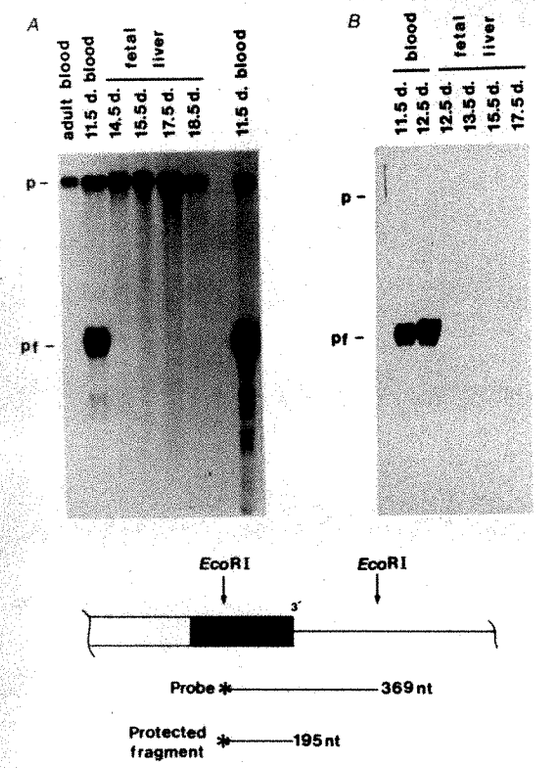

Fig. 3 Detection of endogenous γ-globin mRNA in embryonic blood cells. RNAs from embryonic blood and fetal livers of mice in lines 46 (*A*) and 77 (*B*) were analysed for the presence of mRNA from the mouse embryonic γ-globin gene; 0.1 μg of each RNA sample was hybridized with 3 ng of a 3′ end-labelled, strand-separated probe derived from the 3′ end of the mouse γ-globin gene[13]. The hybrids were digested with S_1 nuclease and analysed by electrophoresis on a polyacrylamide gel containing 7 M urea. p, Position of undigested probe (369 nt); pf, position of the 195-nt protected fragment. The lane marked 'adult blood' is a control hybridization with whole blood RNA from an adult mouse. The two lanes in *A* marked '11.5-day blood' show hybridization with two blood cell RNA preparations from different batches of 11.5-day-old embryos.

Methods. A pBR322 plasmid containing the 6-kb *Hin*dIII mouse DNA fragment including the γ-globin gene[13] was digested with *Eco*RI, 3′ end-labelled with ^{32}P, and the 369-nt fragment shown in the diagram was purified on a strand-separating polyacrylamide gel. The probe had a specific activity of 5×10^7 c.p.m. μg^{-1} and hybridization was performed at 45 °C.

sequence information was suggested by several lines of evidence, such as the observation that deletions several kilobases 3′ to the human γ-globin genes can block their normal postnatal inactivation (reviewed in ref. 31).

Our data do not exclude the possibility that more distant sequences in the β-globin cluster have an important role in regulation of the adult β-globin gene. Indeed, their absence from the microinjected globin gene is one of several factors that may be responsible for the low level of expression observed in the transgenic mice, as discussed previously[7]. However, the ability of a single adult β-globin gene, removed from the context of an intact β-globin gene cluster or 'domain'[32,33], to be nevertheless switched-on at the appropriate developmental stage, argues that distant sequences in the β-globin domain are not required in *cis* for this particular regulatory event to occur. Our results suggest a model in which the switch from embryonic to adult β-globin in the mouse is mediated by the presence of distinct *trans*-acting factors in embryonic as opposed to fetal and adult erythroid cells, which interact with DNA sequences closely linked to the embryonic and adult genes. Whether these regulatory factors are positive or negative, and the number and location of the DNA sequences with which they may interact, are questions that can be addressed by constructing hybrid genes between embryonic and adult β-globin genes, or between globin and non-globin genes[26,27] and examining their developmental regulation in transgenic mice.

Clustering of breakpoints on chromosome 11 in human B-cell neoplasms with the t(11;14) chromosome translocation

The t(11;14)(q13;q32) chromosome translocation has been reported in diffuse small and large cell lymphomas and in chronic lymphocytic leukaemia (B-CLL)[1,2] and multiple myeloma[3]. Because chromosome band 14q32 is involved in this translocation, as well as in the t(8;14)(q24;q32) translocation of the Burkitt tumour[4], interruption of the immunoglobulin heavy-chain locus was postulated for this rearrangement[5,6]. We have cloned the chromosomal joinings between chromosomes 11 and 14 and also

between chromosomes 14 and 18, in B-cell tumours carrying translocations involving these chromosomes[6,7], and suggested the existence of two translocated loci, *bcl-1* and *bcl-2*, normally located on chromosomes 11 (band q13) and 18 (band q21) respectively, involved in the pathogenesis of human B-cell neoplasms[6,7]. The results indicate that in the leukaemic cells from two different cases of CLL, the breakpoints on chromosome 11 are within 8 nucleotides of each other and on chromosome 14 involve the *J*4-DNA segment. Because we detected a 7mer–9mer signal-like sequence with a 12-base-long spacer on the normal chromosome 11, close to the breakpoint, we speculate that the t(11 ; 14) chromosome translocation in CLL may be sequence specific and may involve the recombination system for immunoglobulin gene segment (*V–D–J*) joining.

Our previous analysis of the breakpoint between chromosomes 11 and 14 in one case of B-CLL (CLL 271) indicated that it occurred in the joining (*J*) region[6] of the heavy-chain locus[5] on chromosome 14. Chromosome 11-derived DNA sequences close to the breakpoint in the CLL 271 cells were then used to detect rearrangements of the homologous DNA sequences in neoplastic cells of a patient with a diffuse B-cell lymphoma with the t(11 ; 14) chromosome translocation (LN87) (ref. 6). These initial results indicated that the chromosomal breakpoints in these two cases were close to each other. In the present study we have examined the structure of the chromosome breakpoint in CLL 271 cells and have compared it with another case of B-CLL (CLL 1386).

Using the chromosome 11-derived DNA probe near the chromosomal breakpoint on the 14q$^+$ chromosome from CLL 271 (Fig. 1; ref. 6), we screened DNAs from several human B-cell neoplasms for rearrangements of the homologous DNA sequences and detected rearrangement in sample CLL 1386. Frozen CLL 1386 cells stored in liquid nitrogen were defrosted, stimulated to divide with B-cell mitogens[8] and karyotyped. CLL 1386 cells were found to have the characteristic t(11 ; 14) (q13 ; q32) translocation (Fig. 2).

Southern blots of *Bcl*I, *Hin*dIII and *Sst*I digested DNAs derived from CLL 271, CLL 1386 and LN87 were then hybridized with probes *a* or *b* (see Fig. 1*B*). We detected germline restriction fragment(s) in normal human DNA, whereas an additional fragment, depending on the restriction enzyme and probe used, was found in CLL 271, CLL 1386 and LN87 DNA (Fig 1*A*).

The results shown in Fig. 1*A* indicate that the breakpoint in CLL 271 is between the *Sst*I^1 and *Hin*dIII^2 sites and the breakpoint of LN87 is between the *Hin*dIII^2 and the *Sst*I^2 sites. Digestion of DNA from another case (CLL 1386) with *Sst*I did not result in the appearance of a rearranged DNA fragment, so the chromosome 11 breakpoint may be mapped between the *Hin*dIII^1 and the *Sst*I^1 sites. However, CLL 1386 DNA shows only a germline *Hin*dIII^1/*Sst*I^1 fragment (data not shown). Because the breakpoint of CLL 1386 is mapped close to the *Sst*I^1 site in the *Sst*I^1/*Hin*dIII^2 fragment, the result of digestion of CLL 1386 DNA with *Sst*I (shown in Fig. 1*A*) may reflect co-migration of a rearranged fragment with a germline DNA fragment.

We attempted to clone the joining between chromosomes 11 and 14 on the 14q$^+$ chromosome of CLL 1386 cells to compare it with that in CLL 271 cells, which we had already isolated[6]. The DNA of CLL 1386 cells was partially digested with *Sau*3A restriction enzyme and DNA fragments of 15–23 kilobases (kb) were collected by size fractionation using sucrose density gradient centrifugation. These were ligated to the λ phage vector EMBL3A DNA (ref. 9) and packaged *in vitro*. By screening 200,000 recombinant clones with probes *a* and *c* (Fig. 1), we obtained five independent clones. Two of the five clones also hybridized with a probe specific for the heavy-chain locus joining (J_H) segments (pHj)[6], indicating that they contained the joinings between chromosomes 11 and 14 on the 14q$^+$ chromosome and also that the breakpoint on chromosome 14 was close to the J_H region. The restriction maps of the region surrounding the 11 ; 14 chromosome joinings in CLL 1386 cells and of the corresponding normal chromosome 11 and the breakpoint in CLL 271 cells

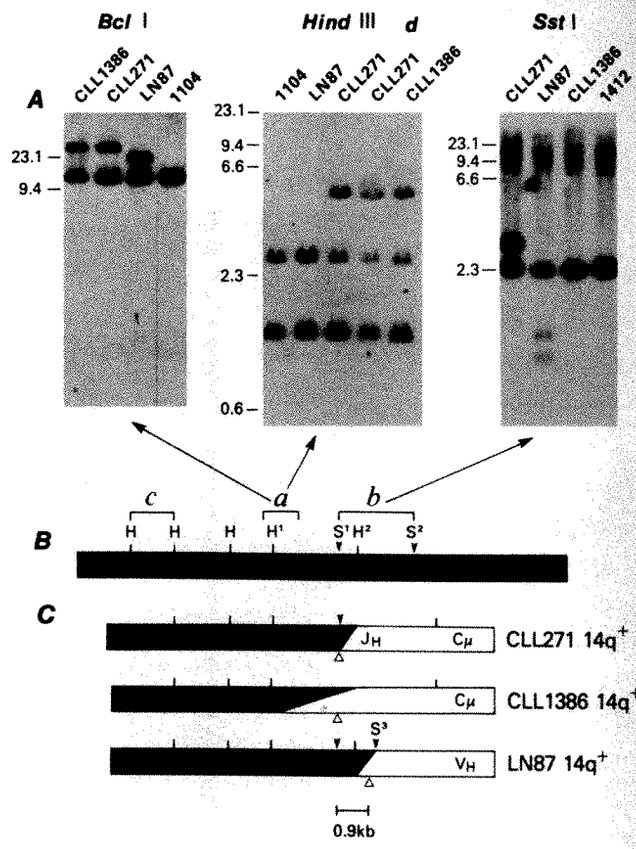

Fig. 1 Southern blot hybridization of CLL 271, CLL 1386 and LN87 DNA with human chromosome 11-derived probes (*A*) and the maps of chromosome 14q$^+$ in CLL 271, CLL 1386 and LN87 (*C*) and of normal chromosome 11 (*B*).
Methods. *A*, DNAs derived from neoplastic cells of CLL 271, CLL 1386 and LN87 were cut with the restriction enzymes shown, run on 0.7% agarose gels and transferred to nitrocellulose filters. The filters were hybridized with nick-translated probe *a* (pRc8SmR)[6] or *b* (shown in *B*). Hybridizations were carried out in 50% formamide/4 × SSC at 37 °C and finally washed with 0.2 × SSC at 65 °C. DNA 1104 and 1412 were obtained from T-cell lymphomas and used as germline control for chromosome 11. The size is shown in kb beside each panel. *B*, *C*, Structure of normal chromosome 11 in *B* is deduced by analysing the chromosome 11 sequence-containing recombinant clones in Fig. 3 obtained from CLL 271 and CLL 1386 genomic phage libraries. Filled box and open box show chromosomes 11 and 14, respectively. The cleavage sites by restriction enzyme *Sst*I and *Hin*dIII are shown by S (▲) and H (|), respectively. All restriction sites are not shown. Open triangles represent the joining sites between chromosomes 11 and 14 on chromosome 14q$^+$ which are determined as described in the text.

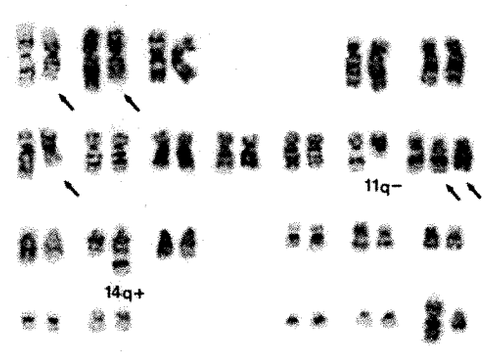

Fig. 2 Representative Giemsa-banded karyotype from CLL 1386 interpreted as: 47, XY, del (1) (p11p21) (q22q25), del (2) (q31), del (6) (q13–15), t(11 ; 14) (q13 ; q32), inv (12) (p13q13), +inv (12) (p13q13). Abnormalities other than the t(11 ; 14) translocation are indicated by arrows.

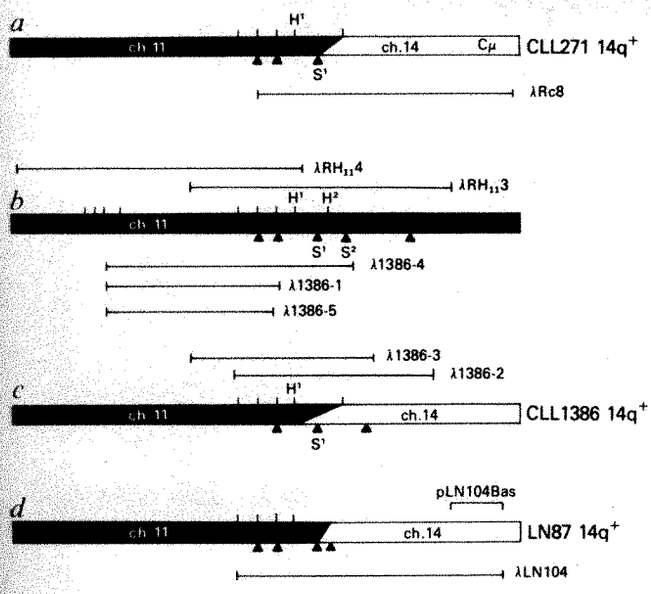

Fig. 3 Restriction maps of the regions surrounding the breakpoints on chromosome 14q$^+$ in CLL 271 (*a*), CLL 1386 (*c*), LN87 (*d*) and of normal chromosome 11 (*b*). Filled and open boxes represent chromosomes 11 and 14, respectively. Horizontal lines represent the insert DNAs of representative recombinant clones. λRc8 has been described previously[6]. λ RH11-3 and -4 were obtained by screening the CLL 271 library with chromosome 11 sequences. λ1386s were obtained from the CLL 1386 library as described in the text. λ1386-1, 4 and 5 all contain only DNA sequences of chromosome 11. The cleavage sites of restriction enzyme *Sst*I and *Hin*dIII are shown by H (|) and S (▲), respectively.

are shown in Fig. 3. As more detailed restriction mapping showed that the chromosome 11 breakpoints in CLL 271 and CLL 1386 are both very close to the *Sst*I[1] site (data not shown), we determined the nucleotide sequences surrounding these breakpoints, and the corresponding segment of normal chromosome 11 from CLL 271 cells. The sequences obtained are shown in Fig. 4, and indicate that the first 31 bases following the common *Sst*I[1] site are identical between the normal chromosome 11 and the 14q$^+$ joining region of the two CLLs. The sequences first start to diverge between normal chromosome 11 and the 14q$^+$ segment of CLL 1386. Then, just 8 bases further, the DNA sequences of the normal chromosome 11 and that of the 14q$^+$ joining region of CLL 271 diverge.

Because the breakpoint on chromosome 14 in CLL 271 cells was mapped in the J_H region of the immunoglobulin heavy-chain locus[6], we expected to find DNA sequences of the J_H region beyond the breakpoint. As shown in Fig. 4, beyond the breakpoints of both CLL 271 and CLL 1386 cells, the DNA sequences are almost identical to the *J*4 segment of the heavy-chain locus[10], although there are some unidentified sequences between the breakpoints on chromosome 11 and chromosome 14 of both cases. Addition of a few extraneous nucleotides during variable-diversity-joining (*V-D-J*) segment joining has been described[11].

Thus the breakpoints of CLL 271 and CLL 1386 on both chromosome 11 and chromosome 14 are very close to each other. Although the short sequence of 9 bases between the breakpoints on chromosomes 11 and 14 in CLL 271 is of unknown origin, the comparable sequence in CLL 1386 between chromosome 11 and 14 sequences on the 14q$^+$ chromosome shows some similarity to the corresponding region on the normal chromosome 11. Therefore, this sequence in CLL 1386 cells seems to have been generated by disturbance of normal chromosome 11 sequences during the translocation event. This may move the breakpoint on chromosome 11 in CLL 1386 slightly closer to chromosome 14 sequences. DNA sequences 3′ to *J*4 coding sequences are identical in the 14q$^+$ chromosomes of CLL 271 and CLL 1386, although these sequences show a considerable number of base changes from the published DNA sequences 3′ to the *J*4 segment[10].

Note also that the breakpoints on chromosome 14 in both our cases of CLL are in the region where the *D* segment is joined to the J_H segment during normal *V-D-J* joining to produce an active immunoglobulin gene. This surprising finding suggests the involvement in the t(11;14) translocation of a recombinase responsible for *V-D-J* joining. This putative recombinase is thought to recognize conserved DNA sequences called '7mer-9mer', located close to *V*, *D* and *J* segments of immunoglobulin genes in germline DNA[12]. It has been proposed that the 7mer-9mer sequence with a 12-base-long spacer is paired with a 7mer-9mer sequence with a 23 ± 1-base-long spacer during *V-D-J* joining[12]. Interestingly, as shown by brackets in Fig. 4, DNA of normal chromosome 11 has a sequence very similar to this conserved 7mer-9mer signal sequence, very close to the breakpoint. This 7mer-9mer sequence on chromosome 11 is separated by a 12-base-long spacer, whereas the 7mer-9mer sequence of the *J*4 segment is separated by a 23-base-long spacer. These two sets of sequences can be drawn into a secondary structure, as shown in Fig. 5. Although the complementarity between the 7mer of chromosome 11 and the *J*4 segment is not very striking (3 bases in 7), this complementarity does not seem to be absolutely necessary even for normal *V-D-J* joining. The 7mer sequence on chromosome 11 is perfectly palindromic, which is one of the characteristics found in most 7mer sequences[12]. The homology to the consensus 9-mer is much stronger (8 of 9 residues). Thus, the t(11;14) chromosome translocation in two separate cases of CLL seems to be sequence specific, suggesting that the recombination system for *V-D-J* joining is involved, and that the translocation may be mimicking normal *V-D-J* joining. This also suggests that the putative recombinase can function even between two independent chromosomes.

The restriction map of the DNA region encompassing the breakpoint of the t(11;14) translocation in a diffuse B-cell lymphoma (LN87) and of the corresponding normal chromosome 11 are also shown in Fig. 3. The recombinant clone contain-

Fig. 4 DNA sequences of the joining sites between chromosomes 11 and 14 in CLL 271, CLL 1386 and of corresponding normal chromosome 11. Identical nucleotide sequences are shown by vertical lines. The boxed region indicates the *J*4 coding segment of the immunoglobulin heavy-chain gene[10]. The DNA sequences shown by brackets on chromosome 14 indicate the conserved sequence 7mer-9mer (see text). DNA sequences were obtained from the *Sst*I[1] (S[1]) site shown in Fig. 3 to the chromosome 14 sequence by using the chemical degradation method of Maxam and Gilbert[14] with a modification of the A reaction[15].

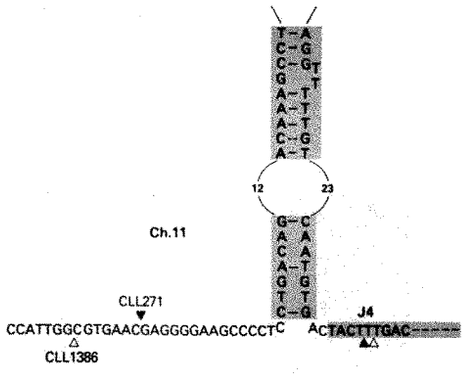

Fig. 5 A possible secondary structure between chromosome 11 and the *J*4 segment of the immunoglobulin gene.

ing the breakpoint was isolated from an LN87 genomic library as described above. The chromosomal breakpoint in LN87 cells was mapped very close to the *Sst*I[2] site in Fig. 1*B* by comparing the detailed restriction maps of normal chromosome 11 clones and a breakpoint-containing clone (data not shown). The chromosome 11 breakpoint in these cells is thus ~0.9 kb away from the site in the two CLLs. In addition, the breakpoint on chromosome 14 in LN87 cells seems to be quite different from that of CLL 271 and CLL 1386. It seems to be either 5′ to or within an immunoglobulin *V*-region gene, because a DNA probe, pLN104Bas (see Fig. 3), hybridized with multiple restriction fragments of human genomic DNA (data not shown). Such a pattern is characteristic of immunoglobulin heavy-chain *V*-region sequences[13].

Thus the chromosome breakpoints in the B-cell lymphoma LN87 are different, on both chromosomes 11 and 14, from those in the two CLLs we examined. It is possible that in the case of LN87, a different mechanism may have contributed to the chromosome translocation. Sequence analysis of the joining between chromosomes 11 and 14 on the $14q^+$ chromosome of LN87 cells should provide useful information concerning this issue.

These results also indicate that the breakpoints on chromosome 11 in three cases of B-cell neoplasia with the t(11;14) translocation, two CLLs and one B-cell lymphoma are all sufficiently close as to be detected by genomic Southern blot hybridization using a single restriction enzyme such as *Bcl*I and a single DNA probe such as *a* in Fig. 1*B*. This may make it possible to take practical advantage of specific DNA probes for the diagnosis of B-cell leukaemias and lymphomas carrying the t(11;14) translocation.

In vivo somatic mutations in human lymphocytes frequently result from major gene alterations

D. R. Turner, A. A. Morley, Marina Haliandros, R. Kutlaca & Barbara J. Sanderson

Haematology Department, School of Medicine, Flinders University of South Australia, South Australia 5042

Somatic mutations, either spontaneous or produced by identifiable mutagens, are thought to be important in the aetiology of cancer and in the ageing process. The study of somatic mutations in human cells *in vivo* has recently been made possible by the development of techniques for enumeration and clonal expansion of lymphocytes mutated at the chromosome X-linked hypoxanthine phosphoribosyl transferase (HPRT) locus[1,2]. We have studied the molecular basis of *in vivo hprt* mutations in human lymphocytes and report here that a surprisngly high proportion (57%) involve substantial gene alterations which are not evident cytogenetically. These major gene alterations include deletions, exon amplifications and novel, sometimes amplified, bands on Southern analysis. Such changes emphasize the fluid nature of information in DNA and may be indicative of general mechanisms by which functional gene loss is involved in the aetiology of cancer and the homeostatic failure of ageing.

Mutant $HPRT^-$ cells can be selected for by the purine analogue 6-thioguanine (TG) as described previously[1,3]. Lymphocytes obtained from the blood of healthy adult males were cloned at limiting dilution either in the absence of TG (unselected, presumably $HPRT^+$ clones) or in the presence of 2.5 $\mu g\ ml^{-1}$ TG (selected, presumably $HPRT^-$ clones). Cloning efficiency in the absence of TG was 15–48% and the frequency of mutant cells ranged from 2.5×10^{-6} to 2.0×10^{-5}. TG-resistant clones were progressively expanded to $>5\times10^7$ cells by the intermittent addition of phytohaemagglutinin, irradiated allogeneic feeder lymphocytes from a female individual, and conditioned medium as a source of interleukin-2 (ref. 1). Genomic DNA was isolated from these monoclonal populations, digested with restriction endonucleases and electrophoresed on agarose gels; Southern analysis[4] was performed using a full-length complementary DNA probe for human *hprt*[5].

We have analysed 12 unselected clones and 21 selected clones from 7 individuals. In most cases, each genomic DNA sample was digested with three restriction enzymes (*Bam*HI, *Hin*dIII

Table 1 Major gene changes observed in 12 spontaneous $HPRT^-$ mutants on Southern analysis

		Change

Clones are listed in arbitrary order. The indication of a change (+) implies a change with respect to the unselected clonal pattern for that donor. Changes indicates are: D, deletion; N, novel band; A, amplified exon; AN, amplified novel band. ND, not done.

and *Eco*RI) for which the coding and pseudogene fragments have been identified[6]. In 12 of 21 (57%) mutant clones, heterogeneous changes in Southern patterns were identified when compared with unselected clones from the same individual. The unselected clones of each individual showed no changes and generally agreed with the gene fragments described by Patel *et al.*[6]. The changes observed in mutant clones include a variety of deletions, and the appearance of novel bands and presumed amplifications of intragenic coding fragments and novel bands (Fig. 1; Table 1). As expected, pseudogenes residing on the autosomes showed no changes in any clone. Southern patterns obtained from one donor showed the same additional gene bands present in all of three selected and three unselected clones examined. We interpret these additional bands present in all six clones to represent a previously undescribed polymorphism and, as this individual subsequently gave a history of gout, family studies are in progress. However, the three selected clones from this individual also showed amplifications of both novel and previously identified coding fragments (Fig. 2). Note that, although these three clones showed similar abnormalities, they were independently derived.

Although major gene alterations of the *hprt* gene were readily detected at the molecular level, parallel cytogenetic studies using block staining and G-banding at the 600-band level showed no structural abnormalities of the X-chromosome in either selected or unselected clones. The messenger RNA products of the mutated genes are being investigated.

It is possible that the results were caused by an *in vitro* rather than *in vivo* phenomenon. However, the experiments involved addition of TG immediately after removal and separation of the lymphocytes and it is known that immediate TG selection results in the elimination of *hprt* gene mutations produced *in vitro*, as there is not time for such mutations to be expressed as a phenotypic change[7]. Therefore, the selected clones must have arisen from lymphocytes which were already mutated *in vivo*. It is formally possible that the initial mutation for each clone did not involve a major gene alteration and that the observed major gene alterations resulted from the emergence *in vitro* of secondarily altered subclones which had a proliferative advantage and which overgrew the original cells of the clone. To test this possibility directly, a subcloning experiment was performed in which lymphocytes were cultured in 96 wells containing TG, each well being subcultured into 12 wells on day 4, at which time any $HPRT^-$ lymphocytes would have undergone several divisions. After growth for 16 days in TG, two sets of subclones were chosen and expanded. Growth was present in 7 out of 12 wells in one set and 6 out of 12 wells in the other; the frequency of wells showing growth in each set indicated that the cells in most of the wells originated from a single cell and thus truly represented a subclone. The genomic DNA of each subclone was studied by Southern analysis and all subclones within each set were found to be identical; all of one set showed no change whereas all of the other (clone 84810F) showed the same *hprt* gene changes (amplification of exons). If major gene alterations develop during *in vitro* growth of lymphocytes, approximately half of each set of subclones should show abnormal Southern patterns and the abnormalities would be heterogeneous within a set. On the other hand, if major gene alterations are present *in vivo*, all subclones of a set would show either no abnormality or an abnormality which is identical for all members of a set. Our observation of the latter case provides direct evidence that the observed major gene alterations were present *in vivo* and had not arisen during clonal expansion *in vitro*.

The present experiments involved conditions of stringent TG selection and only mutations leading to a low or undetectable level of HPRT were likely to be recovered[1]. For this class of mutations, our observations indicate that *in vivo* somatic mutations at the *hprt* locus are at least as likely to result from major gene changes involving several kilobases (kb) of DNA as from more site-specific events such as point mutations or minor deletions. Indeed, it is likely that the observed frequency of gene alterations (57%) underestimates the true frequency, as

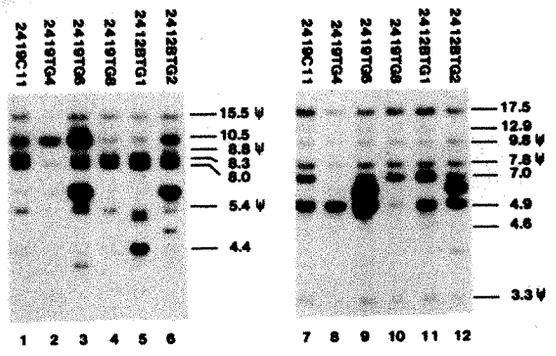

Fig. 1 Representative Southern transfer patterns of unselected ($HPRT^+$) and selected ($HPRT^-$) genomic DNA from two male donors (2419, 2412). Lanes 1–6, *Eco*RI digests; lanes 7–12, *Hin*dIII digests. Lane 1, unselected clone (2419 C11) showing normal enzyme digestion pattern with bands at 4.4 (not previously identified[6]), 5.4 (Ψ), 8.0, 8.3, 8.8 (Ψ) faint in all tracks, 10.5 and 15.5. (Ψ) kb. Lane 2, selected clone (2419 TG4) showing deletion of 8.3-kb band containing exons towards the 5′ end of the gene and a possible amplification of the 10.5-kb band. Lane 3, selected clone (2419 TG6) showing the appearance of a new amplified band of relative molecular mass 6.1 kb and amplification of the 10.5-kb band. Lane 4, selected clone (2419 TG8) which shows no evidence of Southern changes. Lane 5, selected clone (2412B TG1) showing amplification of a band at 4.4 kb and a new band at 5.2 kb. Lane 6, selected clone (2412B TG2) showing appearance of a new band at 6.1 kb, which may be amplified, and also a band at 4.8 kb, Lane 7, unselected clone (2419 C11) showing normal enzyme digestion pattern with bands at 3.3 (Ψ), 4.6 (not previously identified) 4.9, 7.0, 7.8 (Ψ), 9.8 (Ψ), 12.9 (not previously identified) and 17.5 kb. Lane 8, 2419 TG4 showing deletion of 7.0-kb band which hybridizes in unselected clones to the same cDNA fragment as that of the 8.3-kb band in the *Eco*RI digest (deleted in lane 2) and a possible amplification of the 4.9-kb band which correlates with the 10.5-kb band in the *Eco*RI digest of this clone. Lane 9, 2419 TG6 showing amplification of the 4.9-kb band and an amplified novel band at 6.4 kb. Lane 10, 2419 TG8 which shows no evidence of Southern changes. Lane 11, 2412B TG1 showing a possibly amplified band at 7.0 kb with this enzyme. Lane 12, 2412B TG2 showing appearance of a new band at 6.4 kb which may be amplified and a new band at 4.0 kb and a deletion of the 12.9-kb band.

Methods. For Southern transfers, 15 μg of genomic DNA extracted from cultured lymphocytes was digested with restriction enzymes, fractionated on 0.8% agarose gel and transferred to nitrocellulose by minor modifications of published procedures. Hybridization was carried out at 65 °C in 6×SSC 0.5% SDS, 5×Denhardt's, 0.01 M EDTA and 100 μg ml^{-1} sonicated denatured herring sperm DNA following prehybridization in the mixture which was the same except that it contained 250 μg ml^{-1} of the carrier DNA. The probe was a full-length human complementary DNA for *hprt* (insert cleaved from plasmid pHPT30 (ref. 6), *Pst*I/*Hha*I cut, yielding a fragment of 873 base pairs (bp) which has, in addition to the entire coding region, 18 bp of 5′-untranslated and 201 bp of 3′-untranslated sequence). The probe was nick translated to a specific activity exceeding 2.5×10^8 c.p.m. per μg and not less than 5×10^6 c.p.m. ml^{-1} hybridization mix was used. Hybridization was permitted for >16 h. Stringent washing was applied down to 0.5× SSC, 0.1% SDS, 1×Denhardt's at 65 °C. Autoradiographs were obtained on Ortho film using Lanex regular screens at −70 °C. Exposures were typically 48–72 h.

Southern analysis cannot resolve changes below a certain size unless a restriction site is involved. There is no reason to believe that events at the *hprt* locus are more or less frequent than at any other locus and we suggest that such changes in DNA are probably widespread throughout the genome.

It has been reported recently[8] that major changes in Southern patterns were present in 5 of 28 patients with Lesch-Nyhan syndrome. The changes were heterogeneous and included deletions, new bands and, in one family, amplifications. This observation, together with our own, suggests that loss or amplification of genetic material may be an important mechanism for variability in both germline and somatic cells.

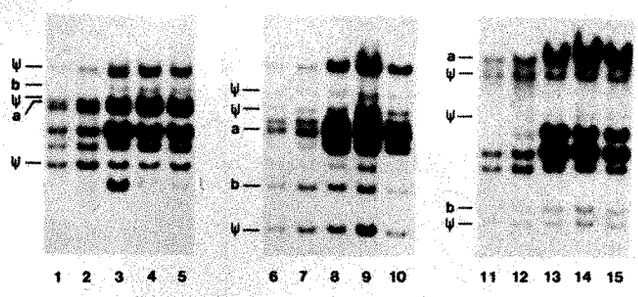

Fig. 2 Representative Southern transfer pattern of genomic DNA probed with cDNA for *hprt*. Two normal human male unselected (HPRT$^+$) clones are shown, 2409 Cl (lanes 1, 6, 11) and 2409 C2 (lanes 2, 7, 12), and three selected (HPRT$^-$) clones from the same individual, 2409 TG1 (lanes 3, 8, 13), 2409 TG2 (lanes 4, 9, 14) and 2409 TG3 (lanes 5, 10, 15). The enzymes used to digest DNA were *Eco*RI (lanes 1–5), *Hin*dIII (lanes 6–10) and *Bam*HI (lanes 11–15). The pseudogene allocations for *Eco*RI and *Hin*dIII digests are given in Fig. 1 legend. For *Bam*HI digests, the pseudogenes are shown at 3.4, 7.6, 14.5 and 25 kb (coincident with a coding region of the X-linked gene)[6]. Pseudogene fragments at 4.2 kb (*Eco*RI) and 2.0 kb (*Hin*dIII) do not show in this autoradiograph. It is clear that even allowing for somewhat greater loading of HPRT$^-$ DNA onto the gel, there has been a significant amplification of certain parts of the *hprt* gene in each of three mutants. In particular, bands labelled 'a' are amplified (*Eco*RI, 8.3 kb; *Hin*dIII, 7.0 kb; *Bam*HI, 22 kb) whereas bands labelled 'b' are not (*Eco*RI, 10.5 kb; *Hin*dIII, 4.9 kb; *Bam*HI, 3.7kb). The former are associated with exons 1 and 2 whereas the latter are associated with exons 3–6 (ref. 6). The simplest explanation of this is that the mutation has been occasioned by multiple reduplications of part of the gene containing exons 1 and 2. We also observe bands in these clones (HPRT$^+$ and HPRT$^-$) which are amplified in the mutants but which have not been previously assigned to the *hprt* gene. These results do not seem to be consistent with a restriction fragment length polymorphism and may therefore represent a non-pathological variant gene. We shall investigate the donor's family in more detail.

Direct evidence for the importance of somatic mutations in cancer comes from recent findings in familial and sporadic retinoblastoma[9] and in Wilms' tumour[10–13]. In both disorders, one autosomal gene at a critical site is believed to be abnormal in all cells as the result of a familial or germ-cell mutation and the other normal allele is believed to have become lost through a chromosomal mutation associated with deletion, inactivation or recombination. Of the 22 cases of Wilms' tumour studied by molecular techniques, chromosomal mutations have been detected in 12, that is 55%, similar to the percentage of *hprt* mutations that we have observed showing major gene changes on Southern analysis. We believe that our observations represent a more general case in that there was no selection or drift during clonal expansion, such as presumably occurs during the development of a tumour phenotype. If, as our findings suggest, somatic mutations generate gene changes in a widespread fashion throughout the genome, loss or amplification of genetic material might be a phenomenon of more general importance in cancer, acting either by causing expression of a recessive abnormal allele as already discussed, by leading to a deletion of regions separating promoters or enhancers from proto-oncogenes and thus producing oncogene activation, or by causing amplification of sequences containing oncogenes, resulting in increases in oncogene products, as has been observed in some neuroblastoma lines[14] and in the human promyelocytic HL60 cell line[15].

Somatic mutations have also been postulated to be involved in the aetiology of ageing. Mutations at the *hprt* locus have been observed to accumulate with age[16–18] and one can readily envisage that accumulating losses or amplifications of genetic material could lead to progressive deterioration of cellular function with age.

This study was supported by the National Health and Medical Research Council and the Anti-Cancer Foundation of the Universities of South Australia. We thank Dr P. I. Patel for prepublication data contained in ref. 6 and Dr C. T. Caskey for supply of plasmid HPT30 containing the human cDNA for *hprt*.

SEWA tumour cells are derived from an osteosarcoma induced in an A.SW mouse by infection with polyoma virus[1]. Cytogenetic analyses have revealed three different characteristic chromosomal abnormalities diagnostic for the presence of amplified genes: 'double minutes' (DMs), homogeneously staining chromosomal regions (HSRs) and C-bandless chromosomes (CMs; for review see ref. 2). DMs may undergo fluctuation in number depending on the conditions in which the cells grow. Their number usually increases after injection of cells into a mouse and often is reduced to undetectable levels when the cells are explanted back into tissue culture; when the cells are re-introduced into the mouse, they again acquire multiple DMs[3]. We show here that cells of SEWA lines carrying DMs, HSRs or CMs contain amplified copies of the proto-oncogene c-*myc* and enhanced levels of c-*myc* messenger RNA and c-*myc* protein. DMs or CMs are the sites of c-*myc* amplification in two different SEWA lines.

We used the SEWA cell lines 4031Tc3 (DMs), StamA (HSR) and Rec4Tc2 (CMs) to screen for amplification of oncogenes (for a genealogy of SEWA cells see ref. 2). Preliminary tests, in which we hybridized a ^{32}P-labelled complementary DNA synthesized from poly(A)$^+$ RNA to nitrocellulose filters containing different oncogene DNAs[4], had provided evidence for abundant c-*myc* mRNA in SEWA cells (data not shown). We therefore investigated whether c-*myc* is amplified in SEWA cells. Total genomic DNA was cleaved with restriction endonucleases, fractionated on agarose gels and blotted to nitrocellulose filters to which ^{32}P-labelled c-*myc* probe was hybridized. For comparison, we tested DNA from testes of the A.SW mouse and DNA from human cells of the COLO 320-DM line, in which an apparently normal c-*myc* allele and a mutant allele rearranged at the 5′ end are each amplified ~25-fold (ref. 5 and M.S. *et al.*, manuscript in preparation). The autoradiographic signal

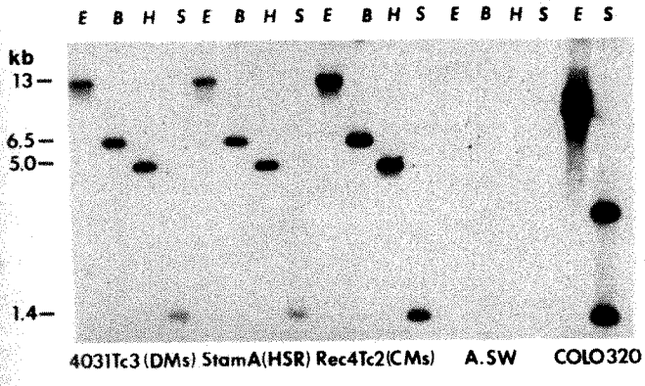

Fig. 1 Analysis of c-*myc* in the DNA of SEWA cell lines. NIH 3T3 and COLO 320-HSR and -DM cells served as controls. Approximately 10 μg of DNA was digested with restriction endonucleases (E, *Eco*RI; B, *Bam*HI; H, *Hin*dIII; S, *Sac*I), fractionated on agarose gel and transferred to nitrocellulose filter, to which ^{32}P-labelled *Pst*I fragment of exon II of human c-*myc* was hybridized. COLO 320 DNA digested with *Eco*RI was from the DM subline, DNA digested with *Sac*I from the HSR subline. DNAs were analysed with a single-copy gene probe (Ha-*ras*) to show that approximately equal amounts of DNA of each line were being used (result not shown).

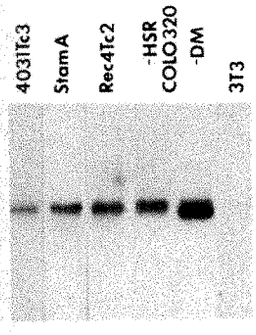

Fig. 2 Characterization of RNA transcribed from c-*myc* in SEWA cells. NIH 3T3 cells and COLO 320-HSR and -DM cells were used for comparison. Poly(A)$^+$ RNA (5 μg per lane) was fractionated on agarose gel in the presence of 2.2 M formaldehyde, transferred to nitrocellulose filters and hybridized to c-*myc* probe.

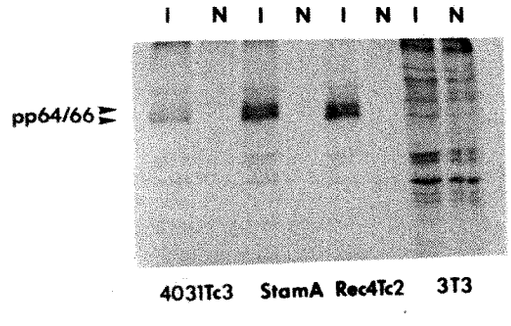

Fig. 3 Immunoprecipitation of pp64/pp66$^{c\text{-}myc}$ from SEWA cells. NIH 3T3 cells were used for comparison. I, immune serum from rabbits immunized with a peptide from the C-terminus of human c-*myc*[6]; N, non-immune serum collected before immunization.

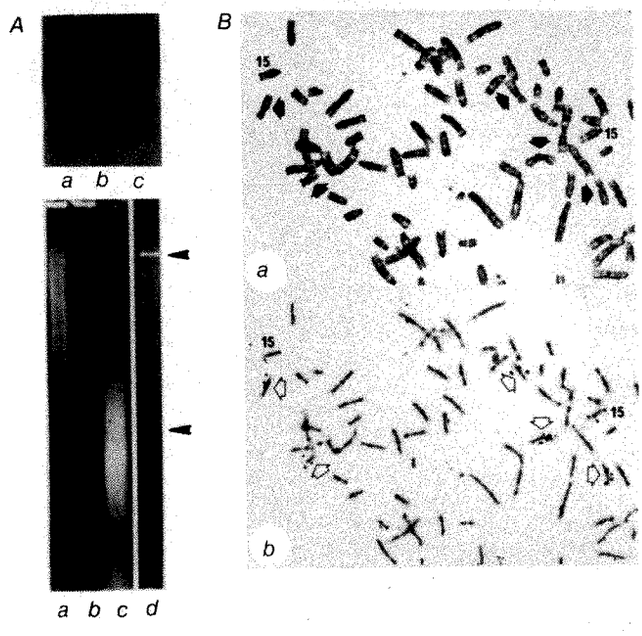

Fig. 4 Presence of amplified c-*myc* in DMs and CMs. *A*, Localization in DMs. Approximately 10 μg of DNA from intact nuclei and undisrupted cells (lane *a*), 5 μg of the fraction containing the macrochromosomes (lane *b*) and an estimated 0.5 μg of the DM fraction (lane *d*) were fractionated on an agarose gel and blotted onto nitrocellulose filter. The upper part of the figure shows the result obtained by hydridizing *myc* probe to the filter, the lower part shows the same gel stained with ethidium bromide. The ethidium bromide stained gel displays the enrichment for specific DNA sequences, presumably repetitive DNA (lane *d*, arrowheads indicate bands due to DNA fragments ~16 and 0.8 kb in size), which do not hybridize with c-*myc* probe, however. The intense fluorescence in lane *c* is probably due to the presence of RNA contained in ribosomes which co-sediment with DMs; the signal disappears following treatment of the gel with pancreatic ribonuclease (lane *e*). *B*, Localization in CMs. SEWAC-3 (a derivative of Rec4) containing CMs was used. Arrows indicate CMs. *a*, Metaphase spread after trypsin/Giemsa treatment. *b*, The same spread after destaining in methanol and *in situ* hybridization to ^{3}H-labelled c-*myc* probe. Note that four of the silver grains in the figure which are not situated over CMs are localized to chromosome 15 (indicated), which contains the c-*myc* gene.

Methods. Approximately 10^8 exponentially growing cells were arrested in metaphase by colchicine (0.05 μg ml^{-1} for 6 h) and collected. Chromosomes were released by gently drawing the cell suspension up and down three times through a 25-gauge needle in chromosome isolation buffer (15 mM Tris-HCl, 0.2 mM spermine, 0.5 mM spermidine, 2 mM EDTA, 0.5 mM EGTA, 80 mM KCl, 20 mM NaCl, 14 mM mercaptoethanol, *p*H 7.2)[9] containing 0.34 M sucrose, 0.1% digitonin and 0.5 M 2-methyl-2,4-pentanediol (Kodak). Nuclei and undisrupted cells were pelleted for 10 min at 500 r.p.m. in a JS 4.2 rotor (Beckmann), and subsequently the macrochromosomes were removed by repeated centrifugation at 4,000 r.p.m. The final supernatant, which on the basis of inspection by light microscopy was virtually free of macrochromosomes, was centrifuged at 25,000 r.p.m. (SW 50.1, Beckmann) for 45 min to pellet the DMs. DNA was prepared from the intact nuclei and undisrupted cells, from the pellets containing the macrochromosomes and from the pellets containing the DMs, and was digested with *Eco*RI.

obtained for the DNA of all three SEWA lines tested was much stronger than that obtained for the DNA from the A.SW mouse. SEWA cell lines 4031Tc3 and StamA contained ~15–20-fold and line Rec4Tc2 ~20–30-fold amplification of c-*myc* (Fig. 1). The size of the DNA fragments detected with the c-*myc* probe was the same in all three SEWA lines and in the normal mouse DNA fragment, indicating that the amplified c-*myc* gene in the SEWA calls has not undergone major rearrangement.

We next used RNA blotting procedures to test whether c-*myc* amplification is associated with a proportional enhancement of the level of c-*myc* mRNA. For comparison, we tested polyadenylated RNA from NIH 3T3 cells and from cells of the COLO 320-HSR and -DM lines containing ~25-fold enhanced levels of mRNA[5]. COLO 320-HSR cells have an mRNA of normal size, ~2.5 kilobases (kb), and COLO 320-DM cells carry predominantly a 2.3-kb c-*myc* mRNA as the result of c-*myc* rearrangement. The size of the c-*myc* mRNA in the SEWA cells and the COLO 320-HSR cells was indistinguishable (Fig. 2). Levels of c-*myc* mRNA in lines 4031Tc3, StamA and Rec4Tc2 were elevated 5–10-fold, 15-fold and 25-fold, respectively, com-

pared with NIH 3T3 cells; the level in Rec4Tc2 cells approached that found in the COLO 320 cells. The mouse c-*myc* gene encodes two forms of the c-*myc* protein, with relative molecular masses of 64,000 and 66,000 (pp64/66)[6]. Immunoprecipitation with anti-*myc* serum[6] showed that the level of c-*myc* protein was greatly increased and that the protein itself was unaltered (Fig. 3).

We have shown recently that DMs and HSRs in several human and murine tumour cells contain amplified cellular oncogenes (for a review see ref. 7). To test whether amplified c-*myc* is localized in DMs of cells of SEWA line 4031Tc3, a chromosomal fraction enriched for DMs was prepared according to the procedure previously used to localize c-Ki-*ras* in DMs[4]. DNA was isolated from intact nuclei and undisrupted cells, from pellets containing the macrochromosomes and from pellets containing the DMs. It was digested with restriction endonuclease *Eco*RI, fractionated on agarose gels and transferred to nitrocellulose paper to which ^{32}P-labelled c-*myc* probe was then hybridized. The autoradiographic signal obtained using ~0.5 μg of DNA from the DM fraction (Fig. 4*A*, upper part, lane *c*) was much more intense than that obtained for 5.0 μg DNA from the macrochromosomes (lane *b*), and only slightly less intense than that seen for 10 μg DNA isolated from total nuclei and undisrupted cells (lane *a*). These results indicate that the DM fraction is enriched for c-*myc* and that DMs are the site of c-*myc* amplification. In another experiment, when SEWAC-3 cells (a derivative of SEWARec4 containing CMs) were hybridized *in situ* to ^{3}H-labelled c-*myc* probe, the average number of grains found over CMs was 10 times greater than that over other chromosomes (Fig. 4*B*, lane *b*), indicating that CMs are the site of amplified c-*myc*.

The generation of DMs following transfer of SEWA cells from *in vitro* culture into the mouse, and the loss of DMs following re-transfer of the cells into tissue culture has long been thought to reflect changes in the copy number of genes involved in malignancy[8]. The present results show that c-*myc* is amplified and overexpressed in SEWA cells and, at least in cells of lines 4031Tc3 and C-3, is probably localized in DMs and CMs, respectively. Although the amplified unit of DNA probably contains considerable genetic information in addition to the c-*myc* gene, it is possible that enhancement of expression of c-*myc* after amplification confers on the host cells a selective advantage for tumour formation in the natural host. This idea is supported by our finding that the degree of amplification of c-*myc* observed in different SEWA lines is correlated with the rate at which tumours develop when the cells are injected into a mouse (T.M. *et al.*, manuscript in preparation). Southern blotting procedures revealed that SEWA cells, which are derived from a polyoma virus-induced tumour[1], contain three to five copies of polyoma virus (data not shown). It is unclear which function, if any, these polyoma sequences contribute to the malignant phenotype in the presence of amplified c-*myc* gene. We are now analysing the possible significance of c-*myc* amplification in SEWA cells in more detail.

These studies were supported by grants from the NIH, NCI, ACS, CANCIRCO, the Swedish Cancer Society, the Erik Philip-Sorensen Foundation and the John and Augusta Persson Foundation.

Size variation in chromosomes from independent cultured isolates of *Plasmodium falciparum*

D. J. Kemp, L. M. Corcoran, R. L. Coppel, H. D. Stahl, A. E. Bianco, G. V. Brown & R. F. Anders

The Walter and Eliza Hall Institute of Medical Research, Melbourne, Victoria 3050, Australia

The complexity of the life cycle of the protozoan malaria parasite *Plasmodium falciparum* has hindered genetic analysis[1]; even the number of chromosomes in *P. falciparum* is uncertain[2]. The blood stages of rodent malaria parasites are haploid[1,3] and hybridization with cloned complementary DNAs similarly suggests a haploid genome in *P. falciparum* blood stages (ref. 4 and our unpublished results). A novel approach to karyoptic and linkage analysis in *P. falciparum* has been provided recently by the technique of pulsed-field gradient (PFG) gel electrophoresis[5], which allows the fractionation of DNA molecules of 30–3,000 kilobases (kb), a range including the sizes of intact chromosomal DNA molecules from eukaryotes such as yeast[5] and trypanosomatids[6]. We describe here the fractionation by PFG electrophoresis of chromosomal DNA molecules from *P. falciparum* into at least seven discrete species which vary in size by up to 20% between different isolates. Several genes for *P. faciparum* antigens which contain repetitive sequences are located on different chromosomes. Surprisingly, two of the chromosomes seem to contain the same sequences.

Intact chromosomal DNA[5,6] was prepared by immobilizing the organisms in low-gelling point agarose and then deproteinizing *in situ* (see Fig. 1 legend). The chromosomal DNA molecules were subsequently separated by PFG electrophoresis in a 1.5% agarose gel. In this procedure, an electric field is applied in alternate pulses first in one direction, then in a direction oriented 90° to the first. Because the DNA molecules are considerably longer than the pore size of the gel, they must align with the field in order to migrate 'end-on' through the gel. As the time to re-orient is a function of size, the molecules can be resolved if the pulse time is tuned to an appropriate frequency[5]. We found that the optimal pulse time for *P. falciparum* chromosomes was ~80 s. The separated chromosomal DNA molecules can then be stained with ethidium bromide (EtBr) and blotted to nitrocellulose for gene localization by hybridization[5].

Fractionation of the chromosomes of cloned *P. falciparum* line E12 (ref. 7), derived from the Papua New Guinea isolate FCQ27/PNG (FC27), is shown in Fig. 1*a*; E12 and FC27 were identical (data not shown). Migration is nonlinear because of the focusing effect of the asymmetrical electrode array[5]. Hence, the DNA molecules in each track lie on a curve, and equivalent bands in successive tracks form a curve across the gel. In the region of highest mobility the DNA formed a smear (S in Fig. 1). Hybridization data (see below) demonstrated that the smear contains fragments of the larger chromosomes, but this does not exclude the presence of other components, for example, mitochondrial DNA or 'minichromosomes'.

In the central region, four sharp bands, designated chromosomes 1–4, were clearly resolved (Fig. 1*a*). To estimate their sizes, yeast chromosomes were used as markers (Fig. 1*c*). The 17 yeast chromosomes were resolved into about 11 bands (Fig. 1*c*) plus a lower band of mitochondrial (YM) DNA. Chromosomes 1–4 of *P. falciparum* clone E12 migrated in the same range as the larger yeast chromosomes. Taking the sizes of the three smallest yeast chromosomes to be about 0.3, 0.5 and 0.7 megabases (Mb) and the largest to be about 2.0 Mb (ref. 5), we estimated that E12 chromosomes 1–4 are roughly 0.8, 1.2, 1.6 and 1.8 Mb in size, respectively. From their discrete sizes and from hybridization data (see below) showing that they contain different sequences, we conclude that they are intact chromosomes.

Nearer the top of the gel, bands were less clearly resolved (see Figs 1–3). Hybridization data (see below) indicate that there are at least three chromosomes in this region. Chromosomes 5 and 6 were usually evident as discrete bands while chromosome 7 smeared from the well, partially overlapping chromosome 6. By extrapolation, we have assigned chromosomes 5–7 nominal sizes of 2.2, 2.6 and 3.0 Mb respectively (Fig. 4), but there are no accurately known size markers in this range. Some EtBr-staining material consistently remained in the well. Hybridization suggested that it contains a poorly reproducible proportion of all the chromosomes, presumably trapped in debris. The possibility of an additional chromosome(s) in this region cannot be excluded.

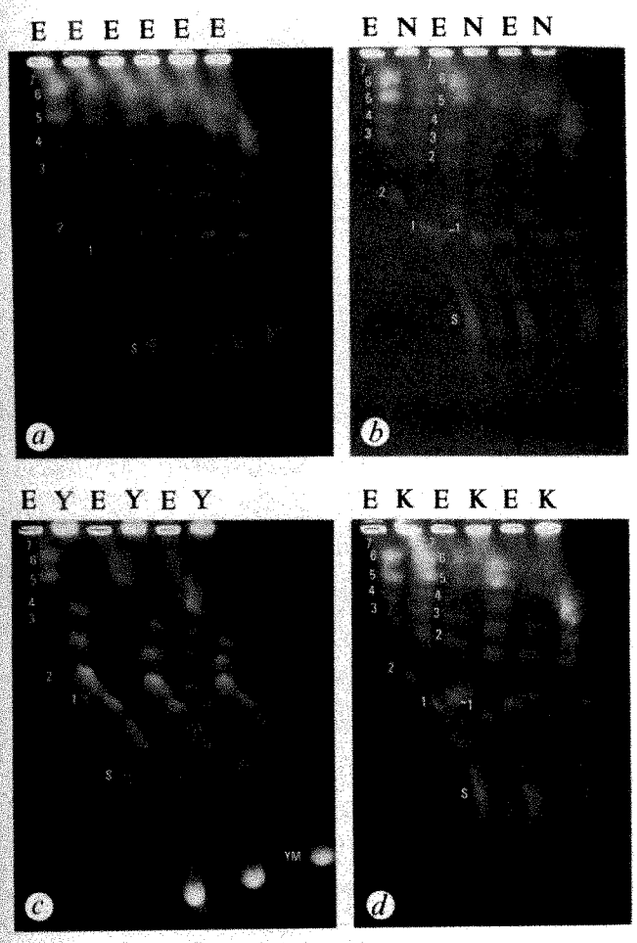

Fig. 1 Fractionation of *P. falciparum* chromosomes by pulsed field gradient gel electrophoresis. In *a–d* the chromosomes were from clone E12 (E) derived from *P. falciparum* isolate FC27, isolate NF7 (N) or K1 (K). The marker chromosomes (Y in panel *c*) were from yeast (*Saccharomyces cerevisiae*, strain J69b1). The samples were run in for 2 h at 200 V in the north–south direction, then electrophoresed for 22 h with 80-s pulses, 250 V in the north–south direction (top–bottom) and 100 V in the east–west direction (left–right) at 18 °C, and stained with EtBr.

Methods. *P. falciparum* isolates were maintained *in vitro*[16] on human erythrocytes. Cultures were collected at 5–10% parasitaemia and the parasites were concentrated by lysing the red cells with saponin[17], followed by two washes. The parasites were resuspended in phosphate-buffered saline at $\sim 6 \times 10^9$ organisms per ml, and added to an equal volume of molten 2% low-gelling agarose in saline at 37 °C, and cast into 1.6 × 5 × 5 mm blocks[5]. The blocks were treated with 0.5 M EDTA/0.01 M Tris/1% Sarkosyl/2 mg ml^{-1} proteinase K for 48 h at 42 °C[5] and stored at 4 °C. Before electrophoresis the blocks were cut into strips ~1.6 × 1.0 × 5 mm, soaked in 0.9 × TBE[5] for 1 h and then inserted into the slots of a 1.5% agarose (Marine Colloids, type ME) gel in 0.9 × TBE and sealed into the slots with 1% low-gelling agarose. Yeast chromosomes were prepared as described previously[5]. The PFG apparatus was constructed essentially as described elsewhere[5], with 15 diode-isolated electrodes in the west, north and east sides and a single electrode in the south-west corner. The gel (225 × 215 × 5 mm) was supported on 2-mm-thick Perspex blocks, to allow cooling by flow of the electrolyte under as well as over the gel. Cooling was achieved by a tap-water heat exchanger and the electrolyte (0.9 × TBE) was recirculated between buffer reservoirs at the north and south ends at 600 ml min^{-1} with a solution metering pump.

Comparison of chromosomes from *P. falciparum* clone E12 with those of isolates NF7 from Ghana and K1 from Thailand revealed striking size polymorphisms (Fig. 1*b*, *d*). Chromosome 1, the smallest chromosome of each isolate, differed in size between the three isolates, as can be seen by comparing the alternate tracks of E12 and NF7 (Fig. 1*b*) and of E12 and K1 (Fig. 1*d*). The sizes of chromosome 1 were estimated to be ~0.8 Mb (E12), 0.9 Mb (NF7) and 1.0 Mb (K1).

No chromosome of a size similar to E12 chromosome 2 was present in NF7 or K1, whereas both NF7 and K1 possesses a chromosome intermediate in size between E12 chromosomes 4 and 5. All three isolates have chromosomes similar in size to E12 chromosomes 3 and 4, but hybridization indicated that this apparent similarity is misleading (see below). All three isolates have chromosomes apparently equivalent in size to E12 chromosomes 5–7, but the resolution is poor in this region.

To clarify the relationships between individual chromosomes in the three isolates, we preparatively isolated FC27 chromosomes by PFG electrophoresis, digested each with *Eco*RI, subcloned the fragments into pUC9 (ref. 8) and hybridized individual chromosome-specific plasmids to blots of E12, NF7 and K1 chromosomes separated by PFG electrophoresis (Fig. 2). Two independent probes that hybridized only to chromosome 1 in E12 also hybridized only to the smallest chromosome in NF7 and K1 (data not shown), as did a cloned cDNA (see below). Hence, the smallest chromosomes of each isolate are counterparts, designated chromosome 1. Hybridization with a probe (pF2.1) specific for E12 chromosome 2 (Fig. 2*b*) revealed that the corresponding chromosome in K1 was much larger (Fig. 2*b*). The same results were obtained with this probe when E12 and NF7 were compared (data not shown). Hence, the second smallest chromosome in each isolate is a counterpart of E12

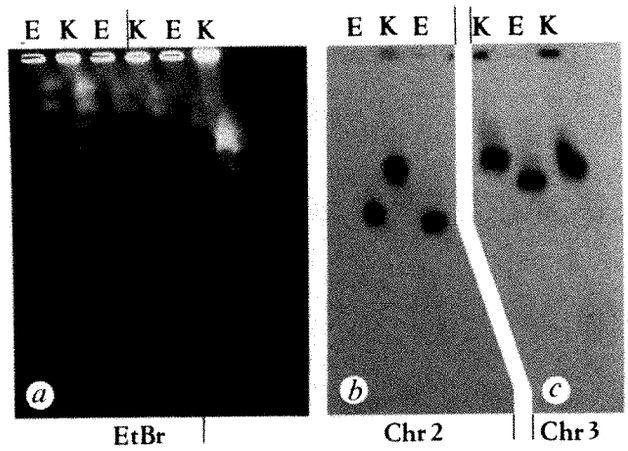

Fig. 2 Relationships between the chromosomes of *P. falciparum* cloned line E12 (E) and isolate K1 (K). Chromosomes were fractionated as in Fig. 1 and stained with EtBr (*a*). The DNA was then blotted to a nitrocellulose filter which was cut into two parts. The left and right parts were hybridized with a cloned FC27 chromosome 2 (*b*) and chromosome 3 (*c*) probe.

Methods. FC27 chromosomes were fractionated as in Fig. 1*a*. Bands corresponding to each chromosome were sliced from the preparative gel, electrophoresed into and then extracted from low-gelling agarose. Chromosome-specific hybridization probes were generated using *Eco*RI digestion of DNA from these individual chromosome bands and ligation of fragments into the plasmid vector pUC9 (ref. 8). Fragments released from the resulting clones pF2.1 and pF3.3 by *Eco*RI digestion were gel-purified, nick-translated and used directly as hybridization probes as described previously[18].

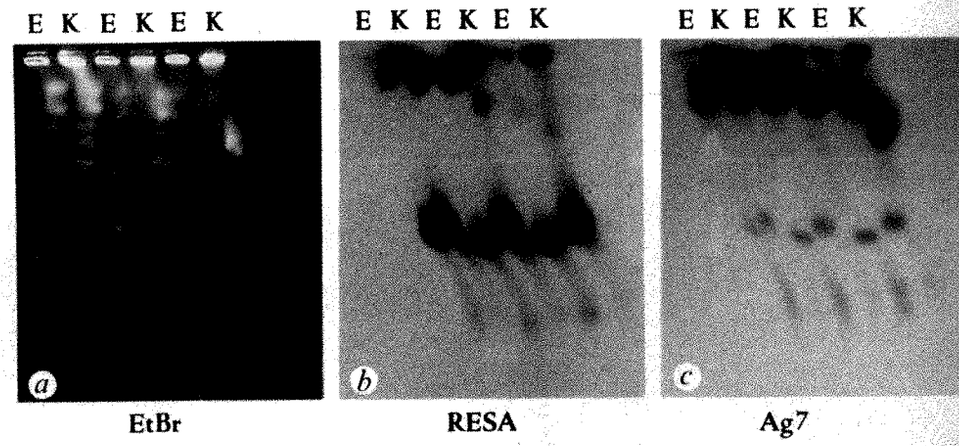

Fig. 3 Chromosomal locations of genes for repetitive antigens. Chromosomes from E12 and K1 were fractionated as in Fig. 1 and stained with EtBr (*a*). The DNA was then blotted to nitrocellulose filters and hybridized with a RESA probe (clone Ag13, from ref. 12) (*b*). After autoradiography, the filter from *b* was rehybridized with a fivefold greater concentration of an Ag7 (ref. 18) probe and autoradiographed again (*c*). Hybridization of both these probes to the origin for K1 is probably an artefact resulting from trapped DNA (see also Fig. 2*c*).

chromosome 2, even though it differs in size by about 0.3 Mb (that is, ~20%) between isolates. Similarly, three independent probes (pF3.3, pF3.9 and pF3.1S) specific for E12 chromosome 3 (Fig. 2*c* and data not shown) revealed that the corresponding chromosome in K1 was considerably larger. Thus, the third smallest chromosome in each isolate is a counterpart of E12 chromosome 3, even though E12 chromosome 3 is considerably smaller (by ~0.2 Mb) than that of K1 or NF7.

K1 and NF7 each contain a chromosome that is intermediate in size between E12 chromosomes 4 and 5. We presume that this chromosome 4 corresponds to chromosome 4 of E12, which is about 0.2 Mb smaller, because we have accounted above for chromosomes 1–3 in each isolate, and hybridization with other DNA probes (see below) shows that chromosomes 5–7 are equivalent (Fig. 4). Remarkably, all four chromosomes that can be clearly resolved are considerably larger in NF7 and K1 than are their counterparts in E12 and FC27.

Several antigens of *P. falciparum* are unusual proteins containing multiple repeats of oligopeptide sequences[4,9-14]. Assignment of these genes by hybridization to separated chromosomes would provide an approach to analysis of the genetic organization of genes coding for these repetitive antigens. Hybridization of a cloned sequence encoding RESA, a repetitive *P. falciparum* antigen located at the membrane of the newly infected erythrocyte[12], indicates that the RESA gene is located on the polymorphic chromosome 1 in both E12 and K1 (Fig. 3*b*). The RESA gene probe also hybridized to chromosome 7 but to a much lower extent, in agreement with our observation that several restriction fragments cross-hybridized to RESA[12]. The gene for a second repetitive antigen, an isolate-specific secreted protein designated the S-antigen[9], was also located on chromosome 7 (data not shown), providing further compelling evidence that chromosome 7 is indeed distinct from chromosomes 5 and 6.

Figure 3*c* shows hybridization of a cDNA probe encoding a third repetitive antigen designated Ag7, which apparently becomes associated with the schizont-infected erythrocyte and contains hexapeptide repeats (our unpublished observations). The Ag7 probe hybridized to both chromosomes 5 and 6 in E12 and K1 (Fig. 3*c*) and in NF7 (data not shown). Its localization on two chromosomes was surprising, as the same Ag7 probe hybridized to a single polymorphic restriction fragment after digestion with *Eco*R1, *Aha*III or *Hin*dIII.

A cDNA probe encoding a fourth repetitive antigen, designated FIRA (for *Falciparum* interspersed repeat antigen, ref. 4) also hybridized to both chromosomes 5 and 6 in E12, K1 and NF7 (data not shown). Again, conventional Southern hybridization had suggested a single gene in each isolate[4], with polymorphisms between isolates. Three other cloned sequences derived from isolated chromosomes (pF5.9, pF5.14 and pF5.17, data not shown) all hybridized to chromosome 5 as well as chromosome 6. Hence, all five sequences that hybridized to chromosome 5 also hybridized to chromosome 6, in each of the isolates including clone E12. This is a paradoxical observation because Ag7 and FIRA are both highly polymorphic (ref. 4 and

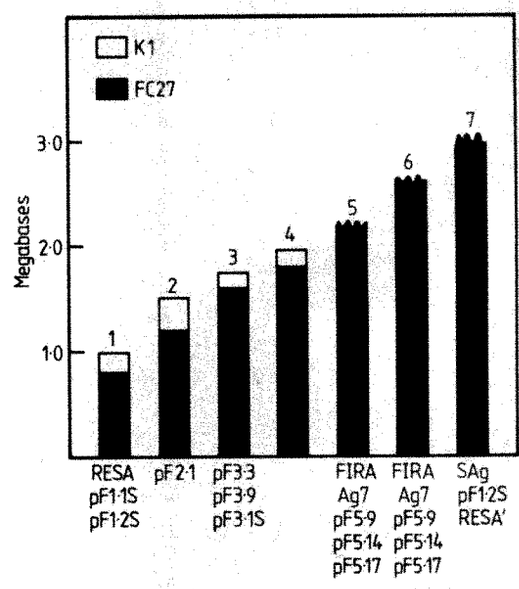

Fig. 4 Karyotypes of FC27 and K1. The heights of the bars represent the approximate sizes of chromosomes 1–7; the wavy lines depicting chromosomes 5–7 imply considerably less accuracy in these sizes. The scale (in Mb) is indicated at the left. Hybridization results are summarized below each chromosome. NF7 was indistinguishable from K1, except that chromosome 1 was ~0.9 Mb. Probes designated pF were generated from isolated chromosomes. RESA' indicates cross-hybridization (Fig. 3*b*).

our unpublished observations). In seven different isolates, including those used here, single restriction fragments were detected by each probe, although the size of these fragments differed between isolates. Hence, each isolate was apparently homozygous at each of these two highly polymorphic loci, so we concluded that the blood stages of *P. falciparum* are haploid, in agreement with genetic studies[1]. However, the single alleles of Ag7 and FIRA present in each of these isolates seem to each reside on both chromosomes 5 and 6. On the basis of EtBr binding, chromosomes 5 and 6 appear to be equimolar and present at the same copy number (presumably 1 per cell) as chromosomes 1–4. A possible resolution of this paradox could be that chromosome 5 is an exact but incomplete copy of chromosome 6. Other variations of this model are obviously possible, the crucial point being that *P. falciparum* appears to be haploid for chromosomes 1–4 and diploid for a chromosome detected as 5–6 because the two copies are of different sizes. At present, we have no independent method to confirm this unexpected observation. It may be an artefact of this new technique, perhaps resulting from chromosome breakage at a specific site.

The data described here illustrate the value of PFG electrophoresis in cytogenetic analysis of a protozoan parasite that

otherwise is genetically intractable. These results show clearly that genes for repetitive antigens are distributed among the chromosomes of *P. falciparum* rather than clustered on one chromosome. The karyotpye of FC27 was remarkably different from those of NF7 and K1, in that chromosomes 1-4 were all considerably smaller, and karyotyping by PFG electrophoresis has enabled us to distinguish these three and another two isolates (7G8 and V1) examined so far.

The phenomenon of uniformly larger chromosomes in one isolate compared with another is reminiscent of differences in the chromosomes of closely related grasshoppers which differ in their content of repetitive heterochromatic sequences[15]. However, deletions occurring *in vitro* could confer a growth advantage and so cultured lines may be rapidly overtaken by such variants. The genetic differences underlying these karyotype differences may be of considerable importance, both clinically and in the efficacy of any future vaccines.

We thank W. Darling and J. Beale for designing and constructing the PFG apparatus and M. O'Halloran, S. Carey and K. Easton for technical assistance. Mismatch-specific post-meiotic segregation frequency in yeast suggests a heteroduplex recombination intermediate

James H. White, Karin Lusnak & Seymour Fogel

Department of Genetics, University of California, Berkeley, California 94720, USA

Post-meiotic segregation of alleles, which is seen, for example, in the 5:3 distribution of alleles in the products of a single meiosis in fungi, has been thought to be due to the non-repair of heteroduplex regions formed during genetic recombination. In current models of genetic recombination, heteroduplex DNA is formed either as the primary intermediate generated by two interacting non-sister chromatids[1] or as a short region flanking a double-stranded gap[2]. The frequency of post-meiotic segregation differs for different alleles, and this is presumed to reflect the varying efficiencies with which different types of mismatches in the heteroduplex are repaired. To gain some insight into this process, we have now determined the nucleotide sequences of various yeast alleles with different post-meiotic segregation frequencies and compared the mismatches predicted to occur in heteroduplexes of these alleles with wild-type DNA with those repaired with varying efficiency in bacterial systems. A striking correlation is observed, with the mismatches predicted for high post-meiotic segregation frequency alleles being similar to mismatches repaired with low efficiency in bacteria. These results support the view that post-meiotic segregation frequency reflects heteroduplex repair efficiency and the contention that meiotic gene conversion is the result of the successful repair of heteroduplex mismatches.

The cloning of the *ADE8* gene has been reported previously[3]. Two methods were used to clone the *ade8-18* allele[4], both in an *ade8-18* host; these were mitotic gap repair[5] and meiotic gene conversion of the *ADE8* plasmid. Figure 1*a* shows a detailed restriction map defining the fragments subcloned for dideoxy sequencing[6] while Fig. 1*b* displays the nucleotide sequence of the *ADE8* gene. The *ade8-18* mutation is a 38-base-pair (bp) deletion removing the third position of codon 88 to the first position of codon 101, inclusively. This accounts for the observed non-revertibility of the allele[7]. The *ADE8* sequence codes for a 214-amino-acid protein, in close agreement with the predicted 232-amino-acid length based on meiotic and X-ray mapping data[7]. The deletion removes a unique *Xho*I restriction site in the coding sequence; this site is absent in both independently isolated *ade8-18* plasmids.

Table 1 Shared sequences in *ADE8* and *ARG4*

Sequence	Location in *ADE8*	Location in *ARG4*
AAGATCC	619	221

TACAAAGGG	574	525

Numbering for *ADE8* begins with the first nucleotide in Fig. 1*b*. For reference, nucleotides 646-683 are deleted in the *ade8-18* mutation. Numbering for *ARG4* begins with the first nucleotide in Fig. 2. For reference, *arg4-17* is at nucleotide 164 and *arg4-16* is at nucleotide 378.

Figure 2 shows the nucleotide sequence of the 566-bp *ARG4* *Sst*I fragment. The ochre mutation *arg4-17*, with low post-meiotic segregation, is an A to T transversion in the first position of codon 43. The plasmids pSZ524 and pSZ524-17 (provided by T. Orr-Weaver and J. Szostak) were the sources of *ARG4* and *arg4-17* DNA. The *arg4-16* mutation, showing high post-meiotic segregation, is a G to C transversion in the second position of codon 114, substituting proline for arginine. The *arg4-16* allele was cloned by mitotic gap repair[5]. The *ARG4* sequence in Fig. 2 agrees with that recently published[8] except at position 346, where we read T instead of G, resulting in aspartate rather than glutamate.

The finding that heterozygosity for the *ade8-18* 38-bp deletion displays high post-meiotic segregation (54% among aberrant tetrads) is unexpected. Previous studies of *HIS4* deletions showed that a 400-bp deletion (*his4-Δ15*) displays gene conversion but no post-meiotic segregation, although a presumed point mutation (*his4-4°*) in the deleted region displays similar non-mendelian segregation levels, but 10.3% post-meiotic segregation[9]. Single-base insertions also seem not to result in high post-meiotic segregation (Table 2). The relationship between deletion size and the frequency of post-meiotic segregation warrants further investigation.

The high frequency of post-meiotic segregation which is characteristic of the *ade8-18* allele does not seem to be a simple

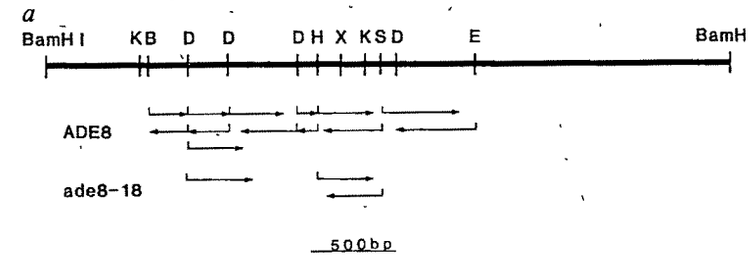

Fig. 1 *a*, Restriction map of *ADE8* DNA and sequencing strategy. The indicated fragments were subcloned into M13mp8 and M13mp9 for nucleotide sequencing by the dideoxy method[6]. B, *Bgl*II; D, *Dde*I; E, *Eco*RI; H, *Hpa*I; K, *Kpn*I; S, *Sal*I; X, *Xho*I. *b*, Nucleotide sequence of the *ADE8* gene. The sequence presented begins with the 412-bp *Dde*I fragment in *a*, and reads from left to right, ending at the consensus poly(A) addition signal[21] in the *Sal*I/*Eco*RI fragment. Putative control regions 5′ to the open reading frame are underlined. The role of the 'amino-acid general control' sequence TGACTC[22] is unknown with regard to *ADE8* transcription. The 38-bp deletion comprising the *ade8-18* mutation is also underlined.

Fig. 2 Nucleotide sequence of the *ARG4 Sst*I fragment. The *ARG4* and *arg4-17°* sequences were obtained from the plasmids pSZ524 and pSZ524-17 provided by T. Orr-Weaver and J. Szostak. The *arg4-16* allele was cloned by mitotic gap repair[5] of *Sst*I-digested pSZ524 in an *arg4-16* host. The three *Sst*I fragments were subcloned into M13mp8 in both orientations for dideoxy sequencing[6]. The *arg4-16* and *arg4-17°* mutations are given below the wild-type sequence.

function of the location of the *ADE8* gene in the genome. When the *ade8-18* heterozygosity was transferred to the *TRP1* locus, the non-mendelian segregation frequency fell from ~10% to the ~1% level observed for *trp1* alleles, yet ~50% of the non-mendelian segregations were post-meiotic segregation events[4]. Similarly, the *ade8-18* post-meiotic segregation frequency does not seem to depend wholly on intragenic location as the *ade8-14* allele is meiotically inseparable yet displays only 11% post-meiotic segregation (S.F. and K.L., unpublished results)[7,10].

The two main recombination models now under consideration provide contrasting predictions for the features determining post-meiotic segregation. Both models feature post-meiotic segregation arising from heteroduplex DNA but differ in the mechanisms which generate this hDNA.

The Aviemore or Meselson–Radding model[1] features asymmetrical DNA strand transfer between interacting homologues, resulting in an extensive hDNA region. DNA mismatches arising in the hDNA are ordinarily recognized and corrected, resulting in gene conversion or (cryptic) restoration. Post-meiotic segregation occurs when such mismatches escape correction during meiosis, and are resolved via subsequent replication. Therefore, specific alleles displaying high frequencies of post-meiotic segregation would be expected to generate hDNA mismatches which are inefficiently corrected.

The double-strand break repair model[2] accounts for recombination through the repair of double-stranded DNA gaps. The process uses a homologous chromatid as the repair template. Short hDNA regions are formed flanking the repaired double-stranded gap. Mismatch repair presumably does not occur in this model, and most mismatches will generate post-meiotic segregation. Rare alleles displaying high frequencies of post-meiotic segregation must occur in hDNA more often and are postulated to create or abut on 'pause sites' for the nuclease activity which enlarges the initial double-stranded break[2]. Such a pause site could halt or retard enlargement of the gap on one or both strands.

The *ADE8* and *ARG4* DNA sequences were searched for shared sequences which could represent pause sites. Thirteen separate sequences of 7, 8 or 9 bp are shared in the regions of

Table 2 Mismatch specificity of post-meiotic segregation in yeast and transformation in *Streptococcus*

S. cerevisiae			*S. pneumoniae*		
Diploid	Mismatch	Post-meiotic segregation frequency	Efficiency class	Mismatch	Relative efficiency
ADE8/ade8-18	38-bp deletion	54.1%	VHE	33-bp deletion	0.86–1.06
ARG4/arg4-16	C/C or G/G	32.5%	HE	C/C or G/G A/G or C/T	0.49–0.64
ARG4/arg4-17°	A/A or T/T	5.3%	IE	A/A or T/T	0.17–0.26
arg4-17°/arg4-17°	A/C or G/T	4.2%	LE	A/C or G/T	0.0026–0.085
HIS4/his4-519	G insertion	0			
HIS4/his4-518	C insertion	0			

The frequencies of post-meiotic segregation are from ref. 9, except *his4-519* (197 tetrads)[18] and *his4-518* (712 tetrads, S.F. and K.L., unpublished results). The *his4-518* sequence is from M. Culbertson (personal communication): ACC→ACCC and the *his4-519* sequence is from ref. 19. The nomenclature for *S. pneumoniae* efficiency classes is from ref. 16, where one to four sequenced examples of each class were reported. The relative transformation efficiencies are from Lacks[15]. Large deletions[15] and presumed frameshifts[20] are usually LE markers in *Streptococcus*. VHE, very high efficiency; HE, high efficiency; IE, intermediate efficiency; LE, low efficiency.

interest (*ADE8 Hpa*I/*Sal*I fragment and *ARG4 Sst*I fragment) (see Table 1). Although one of the sequences abuts on the *arg4-16* site and is also represented only 19 bases away from the *ade8-18* breakpoint, another sequence is equally close to *ade8-18* and the low post-meiotic segregation *arg4-17* site. No new homology is generated by any of the mutations studied in these regions. Therefore, our data neither support nor rule out the presence of a pause site near the two high post-meiotic segregation alleles.

Table 2 lists the *Saccharomyces cerevisiae* hDNA mismatches generated by the alleles whose sequences were determined in the present study. No other data on mismatch repair efficiencies for specific mismatches in *S. cerevisiae* exist. However, post-meiotic segregation is observed for specific G to C transversions creating C/C or G/G mismatches during meiotic conversion of transfer RNA genes in *Schizosaccharomyces pombe*[11]. Analysis of two bacteriophage T4 frameshift mutations which could have arisen through hDNA repair on a quasipalindromic sequence containing a two-base bulge (that is, an insertion relative to the other 'strand') and three sets of base-pair mismatches, G/G, T/G and C/C, yielded one mutant in which all three base pair mismatches had been corrected along with the bulge, while in the other mutant only the C/C mismatch survived the correction process[12].

There is a striking correlation between the *S. cerevisiae* data shown in Table 2 and the relative transformation efficiencies of various markers in *Streptococcus pneumoniae*. Exogenous DNA is converted to single-stranded DNA upon or concomitant with entry into the *S. pneumoniae* cell[13]. The DNA single strands are then taken up by host DNA[13], presumably resulting in hDNA and D-loops in homologous regions. Marker transformation efficiency is interpreted as being a function of the probability of hDNA mismatch recognition[14]. Once recognition occurs, incoming information is excised. Thus, transformation efficiency is inversely related to hDNA mismatch recognition[14]. The right half of Table 2 presents the four identified transformation efficiency classes[15] and the potential hDNA mismatches arising from sequenced examples[16]. Comparisons within Table 2 reveal that the frequency of post-meiotic segregation in yeast and transformation efficiency in *Streptococcus* seem to be based on similarly specific hDNA mismatch correction. Correction of individual base pair mismatches by the methylation-directed system in *Escherichia coli* is also similar. For example, C/C, A/G and C/T are inefficiently corrected, A/A is fairly efficiently corrected and A/C and G/T are well corrected[17].

Based on the above correlations, we are constructing diploid strains harbouring all six possible pairs of mismatches at a single site. These will provide critical information concerning the nature of the meiotic recombination intermediate. If the intermediate is primarily hDNA, the frequency of post-meiotic segregation should vary with the mismatch generated. However, if the intermediate is primarily a double-stranded gap, post-meiotic segregation frequency will depend only on the sequence present on the gapped or recipient chromatid. In this instance, similar post-meiotic segregation frequencies would be expected for all six diploids unless a particular mutant allele creates a pause site not present in the wild-type strain.

In conclusion, we have presented data which comprise a framework for a molecular analysis of the meiotic recombination intermediate. If the intermediate is a double-stranded gap, 54% of the gaps formed near the *ade8-18* site must have a hDNA segment of at least 38 bp, perhaps due to a pause site. On the other hand, we find that the frequency of post-meiotic segregation is correlated with the nature of specific hDNA mismatches analysed and our data therefore suggest a hDNA intermediate. In fact, data for two point crosses at *ARG4* suggest that the A/A or T/T mismatch generated by *arg4-17°* can promote correction of the *arg4-16* C/C or G/G mismatch[9]. Thus, sites separated by 213 bp can be involved in the same hDNA region. If further experiments confirm that segregation frequency is controlled by the structure of the mismatch itself, rather than the sequence environment, it will be possible to estimate more accurately the minimum contribution of hDNA to the meiotic recombination intermediate.

We thank T. Orr-Weaver and J. Szostak for supplying plasmids and J. Carbon for communicating the *ARG4* sequence before its publication. D. Maloney, M. Williamson and A. Blechl provided stimulating discussions and helpful suggestions on the manuscript. This work was supported by NIH grant GM 17317 awarded to S.F.

Why Swissair thinks it important to offer First Class on even the shortest flights.

1. Because many of our passengers will not put up with second best on the ground and we will not ask them to do so in the air.

2. Because we have built up our reputation by putting our passengers' interest first and they do not expect us to lower our standards.

3. Because, for the businessman, flying offers an all too rare opportunity to rest and recuperate, read and reflect and, of course, to eat and drink at leisure. Even on a short flight the tranquillity and ambiance of the Swissair First Class cabin is a welcome antidote to the telephone and meeting room.

4. Because we think first class long-haul passengers are entitled to travel in the same class on European flights.

5. Because more and more passengers enjoy the comfort of our First Class lounges.

6. Because we take pride in providing our passengers with the finest airline service aloft. Swissair First Class Where our specialist staff will welcome you and give that individual attention which is a hallmark of our service. Where you have superb meals and delicacies with a large variety of beverages, all served with the luxurious trimmings of a fine restaurant.

7. Because our spacious Slumberettes on all long distance B-747s and DC-10s ensure absolute comfort whether you are working, or eating, or sleeping peacefully.

8. Because our short-haul flights make an excellent first class appetiser to our long-haul flights covering the Middle and Far East, Africa and North and South America.

9. Because our Business Class and Economy Class are rated so highly we have to have a First Class which is quite outstanding.

10. Because the very best aspects of Swiss hospitality are embodied in Swissair First Class.

Reader Service No.12

"The GLC has taken an essentially negative attitude on most of the major planning issues in London... On several such issues its contribution has been incompetent, irrelevant, or irresponsible."

Kenneth Baker, in Committee debate on Local Government Bill, 15 January, 1985.

In the alterations it has submitted, to the Greater London Development Plan (GLDP) the GLC sets policies and programmes for co-ordinated action to improve London's environment. Among the GLC's own initiatives are:-

Protecting 88,000 acres of Green Belt from major building.
Funding for new country parks, such as Colne Valley and Lee Valley.
Maintaining 20,000 acres of urban parks and open spaces.
Creating large urban parks at Mile End (Tower Hamlets) and Burgess Park (Southwark).
A specialist ecology team to advise on and grant aid work to protect wild life and natural environments.
Redevelopment of obsolete urban environments for community use — Coin Street and Courages.

- Reclaiming polluted lands at Woolwich Arsenal, Battlebridge Basin, and Wandsworth Gas works for housing, recreational and industrial use.
- Reclaiming land spoilt by minerals working for recreational uses.
- Protecting London from flooding and encouraging access to and greater use of the Thames.
- Tackling London's high levels of noise, vibration, air, land and water pollution.
- Protection of and repairs to London's historic buildings and areas, such as Covent Garden.
- The Secretary of State refused to consider alterations to the GLDP; how will their initiatives be continued without a co-ordinated plan and the resources of an elected London-wide planning authority?

Heresy of immanence

John Maddox

The Probability of God. By Hugh Montefiore.
SCM Press, 26-30 Tottenham Road, London: 1985. Pbk £6.95.

ON MATTERS of dogma the Anglican Church has an almost Unitarian god-of-your-choice flexibility, typified by the vicar in the 1960s revue "Beyond the Fringe" who was indistinguishable from a social worker and whose slogan was "Call me Bill; that's the kind of vicar I am". Hugh Montefiore, Anglican Bishop of Birmingham since 1978, is that kind of bishop.

The Probability of God is only marginally a theological work which, in that respect, has much in common with the opinions of the turbulent northern bishops such as the new incumbent at Durham, who is forever shocking the popular newspapers by saying that he doubts the doctrine of trans-substantiation. The real purpose of the book is to demonstrate the immanence of God (or, more ecumenically, I suppose, some God) from the explanatory incompleteness of scientific theories, from cosmology to evolution.

To be frank (and fair), the book is a good and even entertaining read. Over the past few years, Montefiore has taken a serious and continuing public interest in matters such as the environment and arms control. He is both reasonable and earnest, willing to acknowledge that he does not know science at first hand, insistent nevertheless that it must be possible for an honest enquirer to get to the bottom of it (in which he is right) and, then, willing to take up the cudgels in the defence of what seems sanity. If there have to be bishops, nobody could ask for better.

The book is as reasonable as the man. On cosmology, for example, Montefiore does not seize on the big bang as proof that there is (or at least was) a Creator; that, he says, would be "to confuse secondary with primary causes". Instead, he follows the recent writings of Professor Paul C. Davies in emphasizing the numerical coincidences without which life as we know it would not have been possible — the small but not-too-small degree of anisotropy at the beginning that made it possible for galaxies to form; the particular ratio of gravitational and electromagnetic forces which ensures that all stars are not red dwarfs; the particular value of the coupling constant of the strong nuclear force which means that heavy elements (which we need in our enzymes) are stable but which is not so great that the post-big-bang ratio of hydrogen to helium would have been negligible.

Montefiore's refrain is typified by the declaration that "It seems remarkable that the possibility of a planet where life as we know it could evolve should depend upon the precise value of this, the weak nuclear coupling constant". The anthropic principle, which has it that people can observe only a universe conducive to their own existence, is dismissed, but unconvincingly. Lovelock's Gaia hypothesis is a natural next: if the temperature on the surface of the Earth has been that which has been suitable for the survival of living things since the Precambrian, the ups and downs of the solar constant, or the variations of the chemical composition of the atmosphere notwithstanding, does it not follow that there must have been some intervention on behalf of us and our kind?

The texture of the two evolutionary chapters is different, even though Montefiore again begins by not taking the easy way out by letting everything hang on the belief that there has been too little time since the beginning of the Solar System for such a complicated set of living species as are now extant to have evolved. Montefiore argues instead from particular examples, but first asserts that science has made a dogma of natural selection. The rest is a collection of gee-whizz stories, "puzzle after puzzle". Why are our viscera the way they are? Why should *Drosophila* larvae be interposed between egg and adult? Why several independent and apparently successful attempts to evolve an eye? Popper's description of Darwinism as metaphysical (because it cannot be falsified) is mentioned, Popper's recantation is not.

In passing, Montefiore roundly castigates the Creationists, condemns Lysenko, concludes regretfully that there is no hope for Christians in Lamarck but plainly has a soft spot for Dr Ted Steele, the immunologist who caused a minor sensation a few years ago by claiming that immunological genetic changes may be inherited in the germ line. Mystifyingly, he also pats Rupert Sheldrake on the back, noting that the tendency for living cells to assemble in ordered ways can be explained if, indeed, there are "morphogenetic fields" which, for example, guide neurones to the connections with others that make them function properly.

Montefiore's God, therefore, is not a once and for all God, one who drew up the laws of physics and then left us to it, nor a "God of the gaps", one who may have intervened from time to time, but is instead an immanent God, embedded in the Universe and helping to make it tick from one instant to the next. By means of an argument reminiscent of Arthur Koestler's *Roots of Coincidence*, a tract in favour of the paranormal, Montefiore concludes that the nature of the Universe makes the hypothesis of God probable, whereupon more familiar religious arguments lead to Christianity and all that. In passing (and at the outset), he rejects the notion that religion is a code by which people may distinguish ethical and moral behaviour from other kinds of behaviour, and which is therefore orthogonal to rational consideration of the Universe.

Although the cosmological part of Montefiore's argument would fall apart if the ambitions of particle physicists to unify the four forces of nature were to succeed, and demonstrate that the cosmic coincidences can be derived from the laws of physics, the flaw in the whole argument is not in the detail but in the grand design. Montefiore writes as if present scientific understanding of the Universe were complete, as if we shall always be stuck, for example, with the model of the big bang (in its contemporary form, no older than the discovery of the microwave background radiation). It would be an interesting exercise if somebody were to rewrite Montefiore's book at intervals of, say, five years; his natural theology (*pace* David Hume) would repeatedly be found to derive from different sets of circumstances.

Indeed, Montefiore's whole enterprise is more hazardous, and dangerous, than his reasonable tone implies. His immanent God, working in everything, qualifies him as a pantheist. One does not have to go quite as far as Hermann Bondi, whom Montefiore quotes as having described religion as a "dangerous and habit-forming evil", to be deeply suspicious of how pantheism could corrupt the process of scientific enquiry. At what point in the investigation of the evolution of the human eye, for example, will investigators feel free to chicken out, ascribing some parts of the process to natural selection and others to God? Montefiore says his is not the "God of the gaps", but it sounds a bit like the God of the unsolved problems.

Religious belief is common, even among scientists, and, in moderation, is at worst harmless. Many believers are content with what seems to them the sensible position that religious belief is neither dependent on nor even connected with the character of the Universe in which they live and carry out experiments. Others take the view that physical divine intervention ended with the big bang. Explanations of the real world that suppose there is an invisible hand somewhere, making sure that hidden purposes are fulfilled even in the face of the laws of physics are less common but, in their nature, more challenging. Montefiore's book, although honest to the point of saying that "the possibility that there is no God remains open" (but is "wildly improbable"), asks of its readers a concession to irrationality that most will find impossible to make. □

Ringing the changes in chemistry

Robert Ramage

Comprehensive Heterocyclic Chemistry: The Structure, Reactions, Synthesis and Uses of Heterocyclic Compounds.
Chairmen of the editorial board Alan R. Katritzky and Charles W. Rees.
Pergamon: 1984. Eight volumes. £1375, $2200.

HETEROCYCLIC chemistry is a crucially important area of organic chemistry; it embraces a wide range of structural types and applications; and the pharmaceutical industry is, to a large extent, sustained by developments in the structure, reactivity and synthesis of heterocyclic systems. Pergamon's eight-volume series has these three themes as the unifying factor, which has enabled the principal editors and the volume editors to achieve an internally consistent presentation embodying coverage of a remarkable range of topics. The necessary editorial control exercised in the compilation of 154 chapters has not stifled the independent scholarship of the many contributing authors — their collective efforts have resulted in a work which can truly be considered to be "comprehensive".

The series is subdivided into six parts, and the approach adopted by the editors can best be illustrated by the general individual chapters on structure, reactivity and synthesis in Vols 2, 4, 5 and 7. These contributions are not only interesting in themselves but are excellent introductions to the subsequent, more specialized material in each section.

The editors have used Vol. 1 (which constitutes Part 1) to deal with general matters such as nomenclature, review literature, biosynthesis and applications of heterocyclic compounds, thus allowing the following sections to deal more with fundamental principles. In addition, the first volume treats an assortment of lesser known heterocyclic systems which could not easily be assimilated into the accounts of the main heterocyclic systems. Chapter 1.03 on the review literature of heterocycles includes an impressive yet accessible collection of a wide range of references, subdivided into synthesis, reactions and properties, while biological applications are succinctly discussed in chapters dealing with biosynthesis, toxicity, and pharmaceutical, agrochemical and veterinary products. Chapter 1.17 by K. Dimroth, on heterocyclic rings containing phosphorus, is especially impressive in content and organization and will allow chemists to appreciate more fully this less-traditional area of the subject.

Part 2 covers six-membered ring systems incorporating one nitrogen atom (Vol. 2) and then oxygen, sulphur, or two or more nitrogen atoms (Vol. 3). The treatment of these topics is consistent with the general editorial policy of logical development from structure through reactivity to synthesis. Highlights here are Chapter 2.03, a strategic discussion of synthesis of six-membered rings with varying degrees of unsaturation, and Chapters 2.05 and 2.06 which illustrate many facets of pyridine reactivity in monocyclic and bicyclic systems. Volume 2 will certainly provide good background reading in this general area, while the more specialized topics of Vol. 3 are treated in a clear, interesting manner. Together, these two volumes contain the fundamental chemistry required for understanding of many of the biologically important heterocyclic systems.

In Vol. 4 (Part 3 of the series), the approach to five-membered rings containing one hetero-atom is in accord with the pattern set out in the previous volumes. The introductory section (Chapters 3.01, 3.02 and 3.03) has been authoritatively written by C.W. Bird and G.W.H. Cheeseman, and there are useful accounts of the application of spectroscopic methods to structural problems of five-membered heterocycles, resonance and tautomerism. Pyrroles and their benzo derivatives are dealt with in some detail, and are followed by an excellent chapter by K.M. Smith on porphyrins and related compounds which examines in depth the synthesis of simple corrinoids and vitamin B_{12}. The treatment of furan and thiophene chemistry is both a critical and an extensive contribution.

Both Vols 5 and 6 (Part 4) include accounts of a remarkable range of heterocycles containing two or more hetero-atoms. Each class of ring system is treated consistently, and here are to be found heterocyclic types ranging from the biologically important imidazoles and purines to the more specifically chemically interesting systems of importance in organic synthesis.

Volume 7 (Part 5) is used to collate the less voluminous chemistry of heterocyclic systems having small and large rings. The treatment of small-ring chemistry is instructive and well written, although the coverage of β-lactam antibiotics is of necessity rather too brief to be of more than general interest. The chemistry of seven-membered and larger rings is dealt with clearly and concisely, and crown ethers and cryptands are thoroughly reviewed by A.D. Hamilton who takes the subject from consideration of crystal structures to biological and synthetic applications of coordination of these macrocycles containing several hetero-atoms.

The final volume (and part) contains the index, helpfully divided into physical data, author, subject and ring. In addition, the work as a whole benefits from an ingenious reference code system which gives the reader easy access to original papers and source material such as books and reviews.

Comprehensive Heterocyclic Chemistry makes a unique contribution to the literature of organic chemistry. The references quoted are mainly post-1965, and together the eight volumes provide chemists, and biologists working at the chemical interface, with an impressive body of collected knowledge which is not available from any other source. Expensive though it is, chemistry libraries cannot afford to be without this series. □

Robert Ramage is Forbes Professor of Organic Chemistry at the University of Edinburgh.

Bacterial diplomacy

Howard C. Berg

Motility and Taxis in Prokaryotes.
By A.N. Glagolev.
Harwood: 1984. Pp.279. $126.

MODERN work on bacterial motility and taxis dates from the demonstration by Julius Adler (*Science* **166**, 1588–1597; 1969) that the bacterium *Escherichia coli* has specific chemoreceptors: proteins near its outer surface that bind particular amino acids or sugars, causing the cell to respond favourably to changes in its environment, even in the absence of transport or metabolism. This meant that one could study behaviour without having to worry much about energetics, using genetic tricks to unravel steps in the sensory-transductive pathway.

In the Soviet Union, interest in this field was sparked by Vladimir Skulachev, well known for his work on chemiosmotic proton circuits, following the discovery by Larsen, Adler, Gargus and Hogg (*Proc. natn. Acad. Sci. U.S.A.* **71**, 1239–1243; 1974) that bacterial flagella are powered, not by ATP, but rather by the high-energy intermediate of oxidative phosphorylation. Work in the Soviet Union, the United States and Japan has since shown that the immediate source of energy for flagellar rotation is, indeed, the protonmotive force. Alexei Glagolev, a protégé of Skulachev, now raises the Mitchellian banner and argues that $\Delta\tilde{\mu}H^+$ plays an important role in tactic sensing and signalling.

This is a research monograph, not a book for the casual reader. It begins with a compact survey of bioenergetics, summarizes work on the motile mechanics of flagellated cells and gliders, and then presents an extensive discussion of various forms of directed movement, including chemo-, photo-, thermo-, visco- and magneto-taxis. The book brings together the results of a number of experiments described previously by the author and his colleagues in a series of short papers appearing primarily in *FEBS Letters* and *FEMS Microbiology Letters*.

While many of the phenomena described in these papers and reviewed here are striking and warrant serious attention — experiments on the behaviour of long trichomes

of the gliding cyanobacterium *Phormidium uncinatum* are particularly elegant — I find myself sceptical of the work as a whole. A modern-day bioenergeticist comes armed with a number of chemical weapons (ionophores, uncouplers and inhibitors) with which I have had limited experience. How secure are the conclusions drawn from experiments in which such weaponry is applied? These reagents are not all highly specific. For example, the calcium ionophore A23187 has poor selectivity for Ca^{2+} over Mg^{2+} and can even exchange Na^+ for H^+. The ATPase inhibitor DCCD reacts with alcohols and amines, not only with carboxyl groups in hydrophobic pockets. Furthermore, not all such reagents readily penetrate the outer membrane of gram-negative bacteria. The permeability properties of the outer membrane of *E. coli* are reasonably well understood, but what about *Ph. uncinatum, Rhodospirillum rubrum* or *Vibrio harveyi*, to name but a few of the organisms discussed here, or the archaebacterium *Halobacterium halobium*? These systems are complex. More than one function can be perturbed by chemical modification. How is the novice to judge the reliability of this approach when discussions are so brief?

My concern is reinforced by recent results obtained by the genetic approach. For example, by comparing the effects of the inhibitors DCCD and KCN on both phototaxis and motility in *H. halobium*, Glagolev argues that phototaxis in this organism is mediated by changes in $\Delta\bar{\mu}H^+$. This bolsters his argument that sensory systems in bacteria might have evolved from a primitive protometer. However, as he readily acknowledges in his addendum (August 1983), the discovery that phototaxis in *H. halobium* is mediated by a slow-cycling rhodopsin distinct from either bacteriorhodopsin or halorhodopsin — see Spudich and Bogomolni *Nature* **312**, 509-513 (1984) — makes this interpretation highly unlikely. Or take the molecular model for chemotaxis (Fig.38), which includes (i) activation of cGMP by an attractant-receptor-MCP (methyl-accepting chemotaxis protein) complex, (ii) blockage by cGMP of the chemotaxis signal, comprised of a repellent-receptor-CheB (methylesterase) complex, which (iii) affects the flagella by binding to CheZ (a cytoplasmic protein), thus liberating CheC (the flagellar switch) and allowing Ca^{2+}-dependent (possibly membrane potential-dependent) flagellar reversals. As far as I am aware, evidence for the involvement of either cGMP or Ca^{2+} in this process is equivocal, while mutants deleted for *che*B and/or *che*R (the methyltransferase) have normal excitation kinetics. So I find this model speculative in the extreme.

I therefore do not agree with the writer of the book's promotional blurb, who claims that this is "the first rigorous survey of the major new discoveries pertaining to bacterial behaviour". But I do find the book a lively, honest, even exuberant work, full of interesting facts and figures, that carries the discussion of bacterial behaviour well beyond the narrow confines of the *E. coli/S. typhimurium* school.

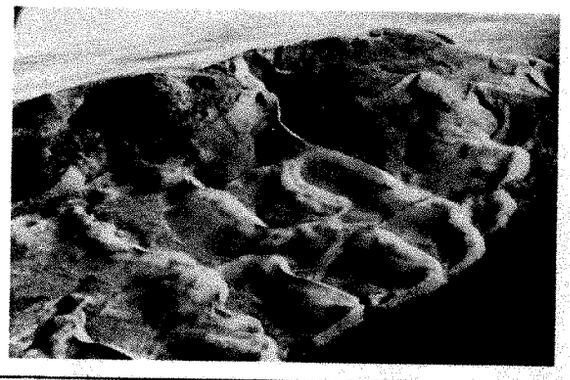
One of the problems, regrettably, is that our Soviet colleagues have not had the benefit of much feedback from the West — one learns a great deal from peer review and the grapevine. Nor have we absorbed as much as we should of their bioenergetic expertise. The channels of communication should be strengthened. We need more bacterial diplomacy. □

Howard C. Berg is Professor of Biology at the California Institute of Technology, Pasadena.

Only natural

L. Crombie

The Chemistry of Natural Products.
Edited by R.H. Thomson.
Blackie/Methuen: 1985. Pp.467.
£46, $75.



ONE of the great barriers to a general appreciation of organic chemistry is the system of structural formulae employed by organic chemists. This is a pity, but understandable. The structural formula, with its dense information content, has evolved to its present form over a century and the practised organic chemist can take in at a glance an enormous amount of precise and detailed scientific information. Like any other language this pictogram system has to be learnt and practised, but once fluency is attained it is easy to use and, mathematical notation apart, is more universally accepted in science that any other language.

The Chemistry of Natural Products is full of such formulae, beautifully drawn and presented, and very helpful they are too. However, despite their plentiful use, the field of natural products is so large that a writer or editor must be very selective in the choice of topics to be covered in a single book. Professor Thomson has assembled a group of ten excellent authors to write about some of the principal sectors of the subject — carbohydrates, aliphatic and aromatic compounds, terpenes, steroids, alkaloids, nucleosides, nucleotides and nucleic acids, amino acids, peptides and proteins, and porphyrins and related compounds. Even so, limitations have had to be imposed. Authors were asked to emphasize stucture, chemistry and synthesis, and make only passing reference to biosynthesis. Additionally, their brief was to describe what has been happening in each of these areas during the past ten years. This of course places some restrictions on the readership which has to have an appreciable basic knowledge of the subject: for such people, however, the book is stimulating and valuable for keeping abreast of developments.

Undergraduates will probably find the chapters too terse and lacking in detailed explanation for direct use, but this should prove to be a useful book to their teachers for updating lecture notes. Postgraduates, especially those undertaking research in this area, will find it invaluable for acquiring a broader, up-to-date view of their subject. However, a price has had to be paid for this wide coverage in that, because of constraints on space, some authors have adopted a rather telegraphic style reminiscent of *Annual Reports of the Chemical Society* or certain of the *Specialised Periodical Reports*. For the purposes of this book, I would have preferred to have seen some reduction in the number of subjects covered and rather more relaxed and extended treatments.

Looking over these various topics, I sense that the contributors were necessarily assigned tasks of unequal difficulty. It is distinctly harder for authors of general sections such as "Aliphatic Compounds" or "Aromatic Compounds" to produce an exciting account because of the diversity of their material. On the other hand, more homogeneous topics — "Porphyrins and Related Compounds" or "Amino Acids, Peptides and Proteins" for example — make attractive reading and were doubtless more pleasurable to write. The book itself is a good example of a stout, well-produced product at an acceptable price. □

L. Crombie is the Sir Jesse Boot Professor of Organic Chemistry at the University of Nottingham.

June meetings

5 June 1985, **Seminar on Laboratory Automation**, London, UK (Marketing Director, V.A. Howe & Co., 12-14 St Anne's Crescent, London SW18 2LS, UK)
10–15 June 1985, **Bari International Conference on F.VIII/von Willebrand Factor-Biological and Clinical Advances**, Pizzomunno Vieste del Gargano, Italy (Dr N. Ciavarella, Hemophilia Centre, Policlinico, University, 70124 Bari, Italy)
25–28 June 1985, **International Symposium on Forest Utilization of Municipal and Industrial Wastewater and Sludge**, Seattle, Washington, USA (K. Grier, College of Forest Resources AR-10, University of Washington, Seattle, WA 98195)

August meetings

24–27 August 1985, **International Conference on the Immonogenetics of Type I Diabetics and Autoimmune Thyroid Disease**, St. John's, Newfoundland, Canada (N.R. Farid, Prof. of Medicine, Chief-Division of Endocrinology and Metabolism, Memorial University of Newfoundland, St John's, Newfoundland, Canada)

September meetings

2–6 September 1985, **International Conference on Atmospheric Carbon Dioxide; Its Sources, Sinks and Global Transport**, Kandersteg, Switzerland (Ulrich Siegenthaler, Physics Institute, Sidlerstrasse 5, CH-3012 Bern, Switzerland)
16–19 September 1985, **European Congress for Artificial Organs**, Athens, Greece (Prof. S. Raptis, M.D. P.O. Box 14127, 11510 Athens, Greece)
16–20 September 1985, **International Meeting on Quantum Chemistry**, Strasbourg, France (Dr A. Veillard, Université Louis Pasteur, Institut Le Bel, 4 Rue Blaise Pascal, 67000 Strasbourg, France).
17–19 September 1985, **International Symposium on Lyme Disease and Related Disorders**, Vienna, Austria (Dr G. Stanek, M.D. Hygiene Institute of the University, A-1095 Vienna, Austria).
30 September–3 October 1985, **European Symposium on Hormones and Cell Regulation**, Strasbourg, France (Dr R.J.B. King, Imperial Cancer Research Fund Laboratories, Hormone Biochemistry Department, PO Box 123, Lincoln's Inn Fields, London WC2A 3PX, UK).

October meetings

3–4 October 1985, **International Meeting on Haemodynamics and Atherosclerosis**, Wellington, New Zealand (Dr W.E. Stehbens, Department of Pathology, Wellington Clinical School of Medicine, Wellington, 2, New Zealand).
3–5 October 1985, **2nd Congress of the European Society of Magnetic Resonance in Medicine and Biology** (with Exhibition), Montreux, Switzerland (Dr M.A. Hopf, 1 route de Florissant CH-1206 Geneva, Switzerland)
8–10 October 1985, **International Congress and Exhibition for Biotechnology**, "Biotechnica", Hannover, West Germany (Deutsche Messe — und Ausstellungs — AG, Messegelande, D-3000, Hannover 82, FRG).
20–25 October 1985, **International Conference on Leukotrienes and Prostanoids in Health and Disease**, Jerusalem, Israel (Prof. U. Zor, Dept. of Hormone Research, Weizmann Institute of Science, Rehovot, Israel 76100)
21–24 October 1985, **International Conference on Pesticides Toxicity, Safety and Risk Assessment**, Lucknow, India (Dr T.S.S. Dikshith, General Secretary of the Industrial Toxicology Research Centre, Mahatma Gandhi Marg, Post Box No. 80, Lucknow - 226001, India).
23–25 October 1985, **Congress of the International Society for Research on Civilization Diseases and Environment**, Budapest, Hungary (Congress Bureau MOTESZ, Budapest PO Box 32, H-i1361, Hungary).
28 October–1 November 1985, **International Symposium on Source Term Evaluation for Accident Conditions**, Columbus Ohio, USA (M. Jankowski, Div. of Nuclear Safety, c/o Int. Atomic Energy Agency, Vienna International Centre, PO Box 100, A-1400 Vienna, Austria).

November meetings

18–21 November 1985, **Scientific Consensus Conference on methods for assessment of the cariogenic potential of foods**, Texas, USA (Dr Dominick P. DePaola, Chairman Consensus Conference Planning Committee, Dean, U.T.H.S.C.S.A., DS 7703 Floyd Curl Drive Antonio, Texas 78284, USA)
25 November–6 December 1985, **International Symposium on Optical and Electro-Optical Applied Science and Engineering**, Cannes, France (J. Prado, Cannes Conference Coordinator, ANRT–Association Nationale de la recherche Technique 101, Avenue Raymond Poincaré, 75116 Paris, France)

Appointments

President Reagan has announced his intention to nominate **Dr John H. Moore** as Deputy Director of the National Science Foundation (NSF). Dr. Moore has been Associate Director and Senior Fellow of the National Science Board, the policy making body of NSF since 1982. Dr Moore would succeed Donald Newton Langenberg.

The Minister of Agriculture, Fisheries and Food has appointed **Dr Robert N. Crossett**, Chief Scientist (Fisheries and Food) of the Ministry, to be a member of the Agricultural and Food Research Council.

Please send 'Announcements' entries to: The Editor, Nature, 4, Little Essex Street, London WC2R 3LF, UK

The KROC Foundation has endowed a $1 million chair at UC-San Francisco to support biomedical research on rheumatic and other immunological diseases. The first holder of the Robert L. Kroc Chair in Rheumatic and Connective Tissue Diseases is **Edward J. Goetzl**, professor of medicine and director of the Division of Allergy and Immunology at UCSF.

Weizmann Institute chemist **Professor Zippora Shakked** has been named first incumbent of the Helena Rubinstein Chair in Structural Biology. Prof Shakked is a member of the Institute's Department of Structural Chemistry, applying X-ray crystallography methods to investigate compounds responsible for the expression of inherited traits.

Professor J. MacMillan, Professor of Organic Chemistry in the University of Bristol, has been appointed as Alfred Capper Pass Professor of Organic Chemistry in succession to Professor Whiting, who is retiring. Professor Whiting will be re-engaged part-time, as Professor of Organic Chemistry.

Dr J.D. Baum has been appointed to Bristol University's Chair in Child Health upon the retirement of Professor N.R. Butler at the end of July 1985.

Dr J.P. McGeehan, Senior Lecturer in Communications Engineering at the University of Bath, has been appointed to Bristol University's Chair in Communications Engineering.

Dr J.W.B. Bradfield, Consultant Senior Lecturer in Pathology at the University of Bristol, has been appointed to Bristol University's Chair in Histopathology.

Awards

The National Science Foundation is offering awards to women scientists and engineers wishing to become visiting professors at US academic institutions. Awards may range from one academic term to 24 months, full or part time, with the usual period being one year. For terms of eligibility and further information write to Visiting Professorships for Women Program, National Science Foundation, Washington, DC 20550.

Miscellaneous

The University of Essex is to offer the UK's first MSc Course in Aerosol Science and Technology from October this year. The one-year course will teach the theoretical and practical aspects of aerosol science and technology with specialist options in atmospheric chemistry and aerosols, and the physics of aerosols. For further information contact Irene Lally, Information Officer, University of Essex, Wivenhoe Park, Colchester, Essex.

Recent Publications for Chemists and Biochemists

from the Royal Society of Chemistry

Natural Product Reports

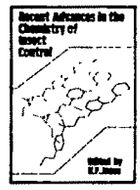
Approx 100 pages per issue.
6 issues per annum
Author and Subject Index (cumulated annually)

Subscription 1985
£125.00 ($242.00)
Rest of World £126.00

Natural Product Reports is a new bi-monthly review journal which commenced publication in February 1984 Natural Product Reports deals exclusively with reviews of natural product chemistry previously covered by a number of books published by the Royal Society of Chemistry – "The Alkaloids", "Biosynthesis", "Terpenoids and Steroids", and "Aliphatic and Related Natural Product Chemistry".
Publication in journal form helps to overcome the problem of overlap and enables reports to be published in a much faster time. Coverage has also been extended to include such areas as chemotaxonomy, enzymology and biosynthetic aspects of biotechnology and advances in physical techniques used for structure determination.
Each issue consists of critical reviews written by leading authorities of worldwide recognition.

Recent Advances in the Chemistry of ß-lactam Antibiotics

3rd International Symposium 1984

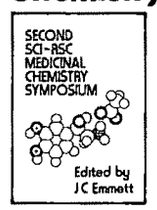


Edited by A G Brown and S M Roberts

Softcover 399pp
ISBN 0 85186 955 6
Price £26.50 ($48.00)

Worldwide sales of anti-bacterial substances amount to ca £6,000M per annum. About 60% of this figure can be allocated to the ß-lactam antibiotics and it can be estimated that ß-lactams account for about 10% of the total drug sales.
Not surprisingly, therefore, many laboratories in academia and the pharmaceutical industry are continuing the search for new and improved anti-bacterial substances based on the ß-lactam template.
This book contains a series of articles which describe the results of research accomplished in recent years.
Contents include:
Recent studies on the Biosynthesis of Penicillins; Do ß-Lactam Antibiotics require a ß-Lactam Ring? The Chemistry of Clavulanic Acid and its Derivatives; The Synthesis of Biological Properties of Recent Cephalosporins, Structure-Activity Relationship Among Some Totally Synthetic Carbapenems
Special Publication No. 52 (1985).

Recent Advances in the Chemistry of Insect Control

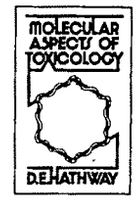


Edited by N F Janes

Softcover 336pp
ISBN 0 85186 965 3
Price £26.00 ($34.00)

This publication covers recent advances in the synthesis and evaluation of highly active compounds in pesticide chemistry such as the avermectins and milbemycins and a range of insect pheromones and antifeedants, aspects of structure activity relationships in insecticides, including pyrethroids (where stereochemistry is highlighted), carbamate propesticides, and juvenile hormone mimics
Contents:
The Biochemical Mode of Action of Insecticides; Stereochemical Aspects of Pyrethroid Chemistry; The Avermectins; Lipophilic Insect Control Agents; Oxime Ethers; New Potent Insect Growth Regulators; Multidisciplinary Studies in the Design of New Insecticides; Some Aspects of Structure Activity Relationships in Pyrethroids; Synthesis and Biological Activity of 2-Indanyl Pyrethroid Esters; New Intermediates for the Synthesis of Pyrethroids; A New Type of Synthetic Pyrethroid Insecticide; Structure Activity Relationships of Methylcarbamoyloximes and Their Sulfenylated Derivatives. Discovery of Thiodicarb; Synthetic Approaches to the Avermectin Toxophore; Synthetic Studies towards the Avermectins and Milbemycins; The Application of Novel Carbanion Chemistry in Milbemycin Avermectin Synthesis; Phytochemical Resources for Pant Protection; Chiral Synthesis: Examples in the Pheromone Field; Synthesis of Some Insect Antifeedants.
Special Publication No 53 (1985)

Second SCI-RSC Medicinal Chemistry Symposium



Edited by J C Emmett

Softcover 342pp
ISBN 0 85186 395 1
Price £24.00 ($43.00)

There are many new and developing areas in the subject of medicinal chemistry. This book attempts to cater for some of the wider interests of medicinal chemists and will provide not only interesting reading, but also food for thought for those involved in active research.
Brief Contents:
Mediator Regulation in Cardiovascular Drug Therapy; The use of Computer Graphics in Drug Design; Biological Challenges to Organic Synthesis; Control of Arachidonic Acid Cascade.
Special Publication No. 50 (1984).

Molecular Aspects of Toxicology

by D E. Hathway

Hardcover 319pp
ISBN 0 85186 068 0
Price £27.50 ($50.00)

Toxicology covers a wide field, which comprises chemical toxicology, cosmetics toxicology, environmental toxicology, food and drugs toxicology, industrial toxicology, pesticide toxicology, and the toxicology of atmospheric pollution, and which involves acute and long-term testing as well as special tests for carcinogenicity, irritation, mutagenicity and teratogenicity. In the testing phases, diagnoses are reached through the disciplines of chemical pathology, clinical medicine and pathology, and in the experimental one, explanation is sought through chemical/biochemical and pharmacological methods.
In such a fragmented field as toxicology with so many diverse practices and specialisms, it is hard to gain an idea of continuity.
This book attempts to unify the subject of toxicology and should be useful to chemists engaged in molecular biology and workers concerned with toxicology and cancer research in particular, as well as to pharmacologists and specialists in drug development and occupational hygiene and medicine in general
Brief Contents:
Part I Toxicity of Foreign Compounds; Part II Relation between Dose and Effect and Time; Part III Metabolism; Part IV Pharmacogenetics, Part V Biochemical Lesions; Part VI Chemical Carcinogenesis, Part VII Toxicant Allergy;

Food: The Chemistry of its Components

by T.P. Coultate

Softcover 202pp
ISBN 0 85186 483 X
Price £5.95 ($11.00)

This book gives a detailed account of the chemistry of the principle substances of which our food is composed. Both the macro-components, and the micro-components, are considered. Throughout the book, Dr Coultate's theme is the relationship between the chemical structure of a substance and its contribution to the properties and behaviour of foodstuffs—whether observed in the laboratory, the factory, the kitchen or the dining room.
Contents:
Introduction, carbohydrates, lipids, proteins, colours, flavours, vitamins, preservatives, EEC numbers of food additives. Subject Index. This book will be of particular benefit to students and teachers of food science and related courses in universities, colleges of further education and schools.
RSC Paperback (1984)

Opportunities with the Ministry of Agriculture, Fisheries and Food

ADAS - Agricultural Science Service
Harpenden Laboratory

Zoologist

...to identify insects and other invertebrates associated with imported plant material, diagnose the presence of pests from damage symptoms, and give guidance to Regional Advisory Entomologists in identification of native invertebrate crop pests. Frequent contact with the British Museum (Natural History) will be necessary.

You should have a good Honours Degree specialising in invertebrate zoology, agricultural zoology, applied entomology or other appropriate subject, with post graduate experience in insect/invertebrate identification or taxonomy. A special interest in a particular insect group or experience in crop pest diagnosis would be an advantage.

Appointment as Scientific Officer. Ref: SB/42/AL

Food Science Laboratory - Norwich

Chemist

...to join a small team investigating the occurrence of mycotoxins in processed foods, contamination of foods from plastic packaging and environmental contaminants in the food chain.

You should have an honours degree in chemistry or related discipline. Experience in trace analysis would be advantageous.

Appointment as Scientific Officer. Ref: SB/65/AE

Food Science Division - London

Chemist

...to be responsible for supervising and training a small team engaged in the determination of pesticide residues in food. You will be expected to develop and/or modify multi-residue methods and to research the degradation of residues after food processing.

You should have an honours degree or equivalent in a relevant subject. Experience in both capillary and packed column gas-chromotography would be advantageous.

Appointment as Scientific Officer. Ref: SB/66/AE

Food Chemist/ Technologist

...to provide advice on all aspects of the manufacture and composition of foods and beverages. You will assist in revising existing legislation, prepare papers on topics of national and international concern and identify information research requirements. The work involves close liaison with industry, Government Departments and advisory committees. No laboratory work is involved.

You must have a good honours degree or equivalent in Chemistry and at least 2 years' post graduate experience. Relevant experience in food technology would be an advantage but a sound scientific training plus the ability to communicate at all levels are of paramount importance.

Appointment as Higher Scientific Officer. Ref: SB/67/AE

Fisheries Research Directorate - Lowestoft

Physical Oceanographer

...to work on all aspects of physical oceanography affecting the movement and dispersion of biological organisms and pollutants in the continental shelf seas around the British Isles. You will provide advice to the appropriate Divisions on oceanographic problems relating to currents and dispersion in coastal waters.

You should have a good honours degree or equivalent in physical sciences or mathematics and at least 2 years' relevant post-graduate experience with proven research ability in dynamical oceanography. A knowledge of computer data analysis, mathematical modelling or dispersion measurement techniques would be an advantage.

RELOCATION ASSISTANCE MAY BE AVAILABLE FOR THIS POST.

Appointment as Higher Scientific Officer. Ref: SB/93/AD

Senior Programmers

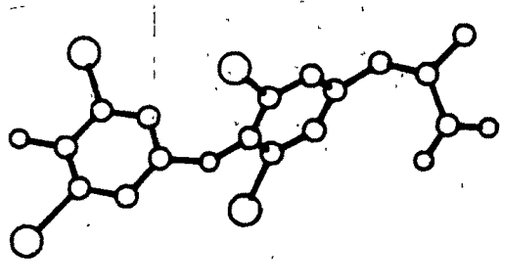
...to be responsible for supporting and developing existing and future computing systems in the Directorate; the design, development and support of large computer applications; management of programmers and liaison with user research sections. The laboratory uses HP1000, HP9000 and Prime minicomputers, Apricot and Torch personal computers, and has RJE links to an ICL2966 mainframe. The main programming language is FORTRAN 77, but increasing use is being made of database packages, including SIR.

HP1000 computers are currently operated on two research vessels and you will be expected to take part in the laboratory's cruise programme, spending up to 4 weeks per year at sea.

You should have a good honours degree in an appropriate subject and at least 2 years' relevant post-graduate experience with knowledge of maintaining and operating a range of computer systems.

Appointment as Higher Scientific Officer. Ref: SB/94/AD

Salaries: Scientific Officer £5905 - £8150; Higher Scientific Officer £7435 - £10,050. Up to £1300 higher in London. Starting salary according to qualifications and experience. SALARIES UNDER REVIEW.



For further details and an application form (to be returned by 14 June 1985) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 468551 (answering service operates outside office hours).

Please quote appropriate reference.

MODEL CHEMISTS

Chemical Design Limited is a British company which specialises in the development of molecular modelling software. With over **100** installations of the ChemGraf system, we consider ourselves to be the leading software company in the field.

We are currently recruiting **FORTRAN PROGRAMMERS** and **SUPPORT STAFF** with experience of:-

- Numerical techniques
- Graphics techniques
- Molecular mechanics
- Quantum mechanics
- Protein structures
- Customer training
- Chemical applications

We offer the best salaries and conditions for the best people.

If you are interested in the possibility of joining us, please write to our Personnel Manager at the address below.

Chemical Design Limited

(6566)A

Biochemical Microbiologist or Parasitologist for Section Leadership

£17,000-£21,500 Beckenham, Kent

The Wellcome Research Laboratories is the main centre for the research activities of The Wellcome Foundation Ltd., a major group of pharmaceutical and chemical companies with headquarters in the UK and a turnover close to £800m.

The major objective of the Department of Biochemical Parasitology (Head: Dr. W.E. Gutteridge) is the discovery and development of novel drugs for the microbial and parasitic diseases of Man, including tropical diseases.

We now require an experienced Biochemist to lead the Department's Biochemistry Section which presently consists of 12 post-doctoral scientists and graduate level technicians. In addition to the line management of the Section, you will take responsibility for the co-ordination of its activities with those of the Department's Biology Section and with research chemists involved in programme work. You will deputise for the Head of Department when necessary and undertake personal research work pertinent to anti-infective chemotherapy, across a broad spectrum of human microbial and parasitic diseases.

The successful candidate will possess a Ph.D. in Biochemistry and at least 10 years' post-doctoral research experience, from an academic or industrial environment, in the biochemistry of bacteria, fungi, protozoa or helminths, preferably in relation to chemotherapy. A demonstrated flair for man-management and for organising and leading scientific research teams, and a sound publication record are essential for this key position. The salary will be dependent upon experience, and excellent benefits include five weeks' holiday, pension fund, sick pay scheme, subsidised restaurant and assistance with relocation expenses where appropriate.

Please write with full personal and career details, quoting reference number WRL/337, to: Dr. H. D. Avshu, Personnel Officer, The Wellcome Research Laboratories, Langley Court, Beckenham, Kent BR3 3BS. (6582)A

Wellcome

PROFESSOR & HEAD Biological Sciences Carnegie-Mellon University

The Department of Biological Sciences invites applications from qualified individuals to serve as Professor and Chairperson. We seek an individual with an established reputation in any field of biological research and an ability to provide leadership in the continuing growth of this department. We expect to appoint the successful candidate by 30 June 1986 or before.

Applications or inquiries should be sent to: Professor W.R. McClure, Chairman, Search Committee, Carnegie-Mellon University, 4400 Fifth Ave., Pittsburgh, PA 15213. ***Carnegie-Mellon University is an Equal Opportunity/Affirmative Action Employer.*** (NW1765)A

ENDOCRINOLOGY BIOCHEMISTRY/ PHYSIOLOGY

Postdoctoral Opportunities

Broad range of Endocrine research projects: (i) isolation and identification of pituitary and lung peptides; (ii) physiologic and pharmacologic action, (iii) growth and control of function of fetal adrenals; (iv) role of growth factors in fetal development.

Send curriculum vitae, bibliography, three letters of recommendation, and short statement regarding career goals, interests and experience to: Dr Samuel Solomon, Endocrine Laboratory, Royal Victoria Hospital, 687 Pine Ave. West, Montreal, Quebec H3A 1A1. (NW1772)A

AFRC Animal Breeding Research Organisation

CELL BIOLOGIST

ABRO is seeking staff to join its expanding Molecular Biology Group in Edinburgh. Research objectives are to investigate the potential of new techniques for genome manipulation of higher animals. A key component of this research will involve gene transfer into tissue culture cells and the examination of signals determining tissue-specific expression.

Applications are invited from scientists with experience of cell culture techniques Persons familiar with procedures for establishing primary cell lines are especially invited to apply.

Candidates should possess a good honours degree in cell biology or a related subject. For appointment at the Higher Scientific Officer level a minimum of two years post-graduate experience is expected. Candidates for recruitment at the Senior Scientific Officer level will normally be expected to possess a PhD or equivalent qualification. Salary will be according to qualifications and experience on the scale £7,435 – £10,039 (HSO).

Applicants should submit a full curriculum vitae together with the names of three referees to: The Secretary, Animal Breeding Research Organisation, King's Buildings, West Mains Road, Edinburgh EH9 3JQ.

The AFRS and the Grant-Aided Institutes of the AFRS are Equal Opportunities Employers. (6565)A

COMMONWEALTH AGRICULTURAL BUREAUX

The leading world agricultural information service for scientists and technologists

SCIENTIFIC INFORMATION OFFICER

at the

Commonwealth Forestry Bureau

Duties include scanning the world literature on forest products, and to some extent foresty in general, and preparing abstracts for the CAB database, mainly for publication in *Forest Products Abstracts.*

A degree in forestry, wood science or a related subject is essential. Some preference will be given to applicants with a reading knowledge of French, German or Russian.

Salary in the scales £5909 to £8153, £7435 to £10039. Starting salary according to qualifications and experience.

Application form and further details can be obtained from:
Commonwealth Forestry Bureau
South Parks Road,
Oxford OX1 3RD
Tel: No. (0865) 57185

Closing date for applications. 15th June 1985.

(6540)A

WORLD SERVICES TO AGRICULTURE CAB

OVERSEAS DEVELOPMENT ADMINISTRATION
THE TROPICAL DEVELOPMENT AND RESEARCH INSTITUTE, LONDON

DIRECTOR

This post falls vacant in November 1985 on the retirement of the present Director, Dr Malcolm Thain.

The Tropical Development and Research Institute is part of the Overseas Development Administration and has a staff of some 400 which includes about 260 scientific and professional grades. It is financed through the British Overseas Aid Programme and has an important role in helping to increase food production in developing countries and in improving food security through post-harvest technology and pest and vector management. It is concerned with the post-harvest and pest control aspects of a range of other tropical products, and also carries out work for other development agencies such as the European Community and FAO.

The Institute, created in 1983 by the amalgamation of the former Tropical Products Institute and the Centre for Overseas Pest Research, is in a period of transition and one of the new Director's main tasks will be to give it firm leadership during this period. Most of the Institute's component parts will be brought together on a new location within reach of London and ODA Headquarters in 1988 and the Director will be required to supervise this move whilst maintaining the impetus of the Institute's scientific programme.
Candidates for the post should be of proven scientific standing, with experience in scientific administration and a knowledge and understanding of overseas development.

The post is Grade 4 in the Home Civil Service, with a present salary of £26,909, currently plus a London Allowance of £1300 a year. The appointment will be for a period of 3-5 years. There may be the possibility of subsequent conversion to a permanent basis. Assistance with relocation expenses may be available.

Applications, including a full CV and details of referees, should be sent to Miss L J Evans, Overseas Development Administration, Room 634, Eland House, Stag Place, London, SW1E 5DH. The closing date for applications will be 5 July; late applications from overseas will be considered if there is time.

ODA OVERSEAS DEVELOPMENT

An equal opportunity employer
(6581)A

Graduate Molecular Biologist

An energetic graduate is required to join a team of molecular biologists at I.C.I. Pharmaceuticals Division engaged in the cloning of both natural and synthetic genes for pharmacologically active proteins. A good first degree in biochemistry, microbiology or a related discipline is required along with some further research experience. Expertise in cloning DNA fragments into plasmid vectors in colony and blot hybridisation analysis and in nucleotide sequencing is required. Additional expertise in isolation of nucleic acids from mammalian cells and in cloning into phage vectors will be advantageous. The jobholder will use a range of techniques with considerable scope for their development and refinement towards the establishment of rapid and robust methods for application to a variety of target genes.

In return we can offer excellent technical and recreational facilities situated in pleasant parkland surroundings, about 15 miles south of Manchester. Our salaries are highly competitive and generous assistance with relocation is available if appropriate.

Applications quoting reference number ICP 932 and including a detailed c.v. should be addressed to:

ICI **Kim Griffiths, Assistant Personnel Officer, Imperial Chemical Industries PLC, Pharmaceuticals Division, Mereside, Alderley Park, Macclesfield, Cheshire.** (6595)A

INSTITUTE OF CANCER RESEARCH

Applications are invited for the following positions based at Sutton, Surrey:—

(1) A THREE-YEAR POSTDOCTORAL FELLOWSHIP

in the areas of computerised molecular modelling and drug design, with special reference to drug-DNA and drug-protein interactions. There is an active and integrated programme of experimental (X-ray, Chemical and Biophysical) and theoretical studies currently under way in several of these areas. Salary in range £7,520 — £8,920 p.a. plus London Allowance of £1,233 p.a. Post available from 1st October, 1985. **Ref. 300/G/13.**

(2) A COMPUTER SPECIALIST

is required for three years to provide programming and systems support for a number of projects involving crystallography, molecular graphics and molecular mechanics of DNA-drug and DNA-protein interactions. The successful candidate will be required to assume day-to-day responsibility for the Unit's computing facilities, comprising VAX, PDP11 and graphics. A strong scientific and computational background in at least some of these areas is required, with **a PhD in crystallography**, molecular modelling or closely related areas. Salary in range £7,520 — £8,920 p.a., plus London Allowance of £1,233 p.a. Post available from 1st July, 1985. **Ref. 300/G/14.**

Applicants are advised that in the majority of the Institute's premises smoking is prohibited

Enquiries to Dr. S. Neidle (01-643 8901, ext. 268).

Applications in duplicate with the names of two referees to the Personnel Officer, Institute of Cancer Research, 17A Onslow Gardens, London SW7 3AL, quoting the relevant reference. (6590)A

TRANSGENE

As a consequence of continued expansion, TRANSGENE, a leading genetic engineering company based in Strasbourg, FRANCE, has immediate openings for scientists in the following positions:

— MOLECULAR BIOLOGISTS

with research experience in the physiology and genetic manipulation of gram negative bacteria, gram positive bacteria or yeast; with a strong background in the latest cDNA and genomic cloning techniques, to work with a group involved in the expression of genes in heterologous systems.

— IMMUNOCHEMIST

interested in the assay, purification and final characterization of natural and cloned porteins using immunochemical techniques.

— PROTEIN BIOCHEMIST

with practical experience of conventional LC, electrophoretic and HPLC techniques for purification and characterization of natural and cloned products. Experience with carbohydrate analysis an asset.

— MICROBIOLOGIST (Gene Expression)

with an interest in practical problem solving at the molecular biology, fermentation interface.

— FERMENTATION SCIENTIST

to work on the laboratory scale fermentation development of recombinant microorganisms. Experience in computing and computer control of fermentation processes would be an advantage.

TRANSGENE is an independent recombinant DNA research and development company, backed by a group of major French industrial and financial organizations.

Interested candidates are invited to submit, in confidence, a full curriculum vitae, a list of publications and the names and addresses of three referees to:

Dr. J.P. LECOCQ
Scientific Director
11, rue de Molsheim

Genetics International (UK) Inc.

We are a rapidly expanding high Technology Health Care Company involved in the development and manufacture of innovative diagnostic systems. We are currently establishing our Quality Control function and we wish to fill the following positions.

Senior Quality Control Technician

Responsible for the control of high volume product and process together with the introduction of Q.C. techniques and methodologies. This person will also assist in the daily running of the Q.C. facility and should be educated to BSc or PhD level in Chemistry/Biochemistry or a related discipline. Previous experience of similar Q.C. work with chemical and/or immunodiagnostic systems (RIA, EIA/ELISA) in the Health Care industry advantageous.

Quality Control Technician — Materials

Responsible for the control of raw materials and components and required to organise and run the Manufacturing stock control/inventory systems for received, in-process and finished goods Qualified to HNC level and ideally with experience of similar areas of responsibility in a manufacturing environment

Quality Control Technicians — Process

Responsible for the analysis of critical materials and for the control of high volume in-process and finished goods using instrument techniques (HPhC, u.v., i.r.).

Educated to BSc level or equivalent in Chemistry/Biochemistry or a related discipline, previous experience of Chemical and/or immunodiagnostic systems (RIA, EIA/ELISA) in a Q.C./Manufacturing environment advantageous.

We are an equal opportunities employer and seek to recruit people for these posts who demonstrate a high degree of initiative, enthusiasm and flexibility with attention to detail. We offer a highly competitive salary and benefits package with real opportunity for career development. Opportunity also exists for participation in the Company Executive Stock Option Scheme.

If you wish to apply for any of these positions please send a letter of application with a full CV and 2 Referees, specifying which position you are interested in to:

Ms F. Minal,
Company Secretary,
G.I. (UK) Inc.,
11 Nuffield Way,
Ashville Trading Estate,
Abingdon,
Oxon. OX14 1RL.

THE ZOOLOGICAL SOCIETY OF LONDON

Institute of Zoology

POSTDOCTORAL RESEARCH ASSISTANT required to join collaborative project on the control of follicular development and ovulation in primates, based at the Institute of Zoology and the Institute of Obstetrics & Gynaecology, Hammersmith. Knowledge of reproductive endocrinology or biochemistry and experience in RIA and cell culture techniques essential

The appointment, MRC-funded and within the MRC/AFRC Comparative Physiology Research Group, is for three years and salary will be at appropriate point of the Society's salary scales (similar to University of London) according to age and experience

Please apply in writing with c.v. and addresses of two referees (enclosing s.a.e.) to the Establishment Officer, Zoological Society of London, Regent's Park, London, NW1 4RY, to arrive before June 15th 1985.

(6541)A

ICI JOINT LABORATORY UNIVERSITY OF LEICESTER RESEARCH TECHNICIAN

Applications are invited for a post of Research Technician (Grade 3) available in the Leicester/ICI Joint Laboratory.

The Joint Laboratory provides an excellent environment for fundamental research in molecular genetics and its staff interact fully with other groups in Biological and Medical Sciences at Leicester and within the sponsoring company. The funding of the laboratory is guaranteed until September 1988 and its extension is subject to periodic review.

The appointee will assist in project involving the application c molecular biological techniques t the study of breast cancer. Previou experience of recombinant DN and/or cell techniques is desirab but not essential.

The post will be for three years, at salary of £5m399 to £6,325 p annum.

Applications, including a cu riculum vitae and the name of tw referees, should be sent to Hele George, ICI Joint Laboratory, Un versity of Leicester, University Roa Leicester LE1 7RH. (6577)A

UNIVERSITY OF OXFORD
NEW BLOOD UNIVERSITY LECTURESHIP IN HIGH ENERGY ASTROPHYSICS

Applications are invited for a new blood University Lectureship in High Energy Astrophysics and related areas tenable from 1 October 1985. This lectureship may be held in conjuction with a fellowship only. It is hoped that a fellowship at another college may be available in due course if a man is appointed.

Further particulars may be obtained from Professor D.E. Blackwell, Department of Astrophysics, South Parks Road, Oxford OX1 3RQ (Tel: 0865-511336/7) to whom applications (eight typed copies or one from overseas applicants) should be sent by 15 June 1985. (6523)A

POSTDOCTROAL POSITION

available to study transmembrane signaling in *Dictyostelium*. Current work is focused on the role of cAMP-induced phosphorylation of surface cAMP receptors in sensory adapation Applicants should have experience in biochemistry, cell biology, or genetics.

Send curriculum vitae and names of three references to: Dr. Peter Devreotes, Department of Biological Chemistry, John Hopkins University, School of Medicine, Baltimore, Maryland 21205. (NW1766)A

A POSTDOCTORAL POSITION

is available immediately to study functional role of insulin in the brain at the cellular level with Drs. DW Clarke and MK Raizada. Experience in cell culture and biochemical techniques is desirable. Experience with immunocytochemistry would be helpful.

Contact: Dr. Mohan K. Raizada, Dept. of Physiology, Box J-274, Univ. of Florida, Gainesville, FL 32610 or telephone (904) 392-3791. (NW1782)A

Senior Pathologist

Internationally respected as a leading name in the field of ethical pharmaceuticals, Smith Kline & French operates intensive and innovative research programmes. This is an opportunity for a man or woman with ambition, initiative, flair and drive to make a significant contribution to our programmes.

We are looking for a person whose experience of the pathology of laboratory animals is coupled with academic ability and an interest in investigative pathology. A veterinary or medical graduate and/or an appropriate research background is desirable. The person should be eligible for MRC Path.

There is considerable scope, the position will be styled to match individual abilities and experience, and research in applied areas will be encouraged. It is a challenge which could interest both experienced pathologists wishing to expand their fields of involvement and also those with a background in experimental pathology and want to enhance their career potential by participating in an expanding department.

There is an attractive salary and benefits include a company car, free BUPA, bonus plan, contributory pension scheme, free life insurance and flexible working arrangements.

Please write for an application form or send a detailed c.v. outlining qualifications and experience, quoting Ref N/122/JW to Tom Forster, Personnel Manager, Smith Kline & French Research Limited, The Frythe, Welwyn, Herts.

TISSUE CULTURE ASSISTANT

Formal applications, accompanied by a curriculum vitae, should be addressed to Dr. S. J. Starkie, Axon Healthcare, Denny End, Waterbeach, Cambs. Further information and job descriptions may be obtained from Mrs S. Imms or Mrs B. Sennitt on (0223) 861224 or +44 223 861224. Previous applicants are encouraged to apply again. (6465)A

DIRECTOR
LABORATORY OF NEUROBIOLOGY
MEDICAL SCIENCES CAMPUS
UNIVERSITY OF PUERTO RICO

Dr José del Castillo is retiring from administrative responsibilities as Director of the Laboratory of Neurobiology of the Medical Sciences Campus of the University of Puerto Rico. Candidates for this position are therefore being solicited. The Laboratory was established in 1967 as an interdisciplinary, interdepartmental research facility with access to the rich and varied local fauna, both terrestial and marine. It has a distinguished history of productivity and of attracting visiting scientists from throughout the world. There are excellent opportunities for further growth. The Director reports directly to the Chancellor of the Medical Sciences Campus and will be offered a tenure track appointment in an appropriate academic department of the School of Medicine. **Candidates should send their Curriculum Vitae and the names of at least three references to: Search Committee, Laboratory of Neurobiology, 201 Boulevard del Valle, San Juan, Puerto Rico 00901.**

The Search Committee will begin evaluating applications on August 1, 1985. The University of Puerto Rico is an Equal Opportunity/ Affirmative Action Employer. (NW1776)A

ROCHE

The *Clinical Pharmacology* group of the **Department of Clinical Research** is responsible for investigation of the *pharmacodynamics* and *pharmacokinetics* of new drugs in humans.

To expand our team, we are looking for a

SENIOR CLINICAL PHARCOLOGIST

with expert training in clinical pharmacology (internal medicine, pharmacology), and an interest in working in research.

This interesting field of work includes the planning, conducting, and evaluation of clinical pharmacology studies of research compounds in phases I — IV.

Pre-requisites are a knowledge of the methods of assessing drug effects in man, and/or pharmacokinetics, as well as a good command of English and possibly German.

Interested applicants are requested to send complete application documentation to our Personnel Department, quoting reference Nature 74/85.

DEPARTMENT OF BOTANY

TWO RESEARCH ASSISTANTS (IA)

Applications are invited for the ab posts in connection with an EEC gr to study (i) regulation of interno elongation and development, and submergence-tolerance of the pho synthetic apparatus, in deepwater ri This crop is particularly important such areas as Thailand a Bangladesh where flooding can ra th water level by 2-5m.

Post 1. (To work with Professor E Cutter and Dr W A Charlton)

Developmental botanist to work the mode of rapid elongation of internodes, its regulation, and the sponses of nodal regions to gravi Experience of light and electi microscopy, and/or hormonal tre ments and extractions, would be advantage.

Post 2. (To work with Dr M J Em

Plant physiologist to look at stability of the photosynthetic ap ratus, following leaf submergen Candidates should preferably h some experience in measuring l fluorenscence induction kinet and/or infra red gas analysis.

Both appointments will be on IA scale (range £7,520 — £8,920) will be for a period of 2 ye beginning July 1st, 1985 or as soor possible thereafter. Candida currently completing a PhD are couraged to apply.

Applications to include full CV the names and addresses of t referees should be sent to eit Professor E G Cutter or Dr. M Emes, Department of Botany, T University, Manchester M13 9PL, later than June 7th. (6572)A

THE DEPARTMENT OF LAND, AIR AND WATER RESOURCES, UNIVERSITY OF CALIFORNIA, DAVIS

announces a position in the area of Soil Science/Plant Nutrition. Tenure track (11 mos. plus 1 mo. paid vacation) position will be divided 30% teaching and 70% research. Appointment will be at the Assistant Professor level.

QUALIFICATIONS: A Ph.D. in a field related to soil or plant science with specialization in mineral nutrition, and strength in mathematics, physics and chemistry. The appointee will develop research on the root-soil interface, involving experimental study and quantitative modeling of chemical and biological processes associated with ion uptake and solute transport. Depending on the appointee's interests, the basic research might be slanted toward a particular application such as nutrient efficiency, stress tolerance, pollutant behavior, soil acidification, symbioses, or control of rhizosphere microbes. The appointee will take part with other faculty in teaching courses in soil science and plant nutrition, advising responsibilities and will develop a graduate course in rhizosphere chemistry and biology.

APPLICATIONS: Applicants should submit curriculum vitae, statements of interests and background in research and in teaching, official undergraduate and graduate transcripts, copies of publications and current manuscripts, and names and addresses of at least three references. Send materials to Dr. D. N. Munns, Chair, Plant Nutritionist Search Committee, Department of Land, Air and Water Resources, Hoagland Hall, University of California, Davis, California 95616, no later than June 13, 1985. Position becomes available July 1, 1985.

THE UNIVERSITY OF CALIFORNIA IS AN AFFIRMATIVE ACTION/EQUAL OPPORTUNITY EMPLOYER. (NW1771)A

DEVELOPMENTAL BIOLOGIST

CORNELL UNIVERSITY MEDICAL COLLEGE

Applications are invited for a senior or junior tenure-track faculty position. Applicants should have at least two years of postdoctoral experience and maintain a research program in early development or morphogenesis, using genetic, recombinant DNA, biochemical, immunological, and/or cell biological tools to explore mechanisms of pattern specification and determination in a vertebrate or invertebrate system. The position includes supervision of graduate students and teaching in a related area.

Send curriculum vitae, research summary, and three letters of reference to: Dr. Rosemary Bachvarova, Developmental Search Committee, Department of Cell Biology and Anatomy, Cornell University Medical College, 1300 York Avenue, New York, NY10021. An Equal Opportunity/Affirmative Action Employer.

POSTIONS OPEN MOLECULAR BIOLOGIST

post-doctoral fellow in second or third year of training. With experience in DNA sequencing or transcription to apply toward the elucidation of the structure and function of fragile sites and their relation to specific cancer chromosomal rearrangements. Salary approximately $20,000 per year, commensurate with experience. **Please submit curriculum vitae, three references, and a brief description of present and future research interests to: Dr. Jorge J. Yunis, Dept. of Laboratory Medicine and Pathology, Box 198 Mayo Memorial Building, University of Minnesota Medical School, Minneapolis, Minn. 55455, U.S.A.** (NW1778)A

THE AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited from suitably qualified men and women for appointment to the following positions:

Research School of Earth Sciences

POSTDOCTORAL FELLOW/RESEARCH FELLOW/ SENIOR RESEARCH FELLOW

NOBLE GAS GEOCHEMISTRY

Applications are invited for an appointment in the School's Geochronology and Isotope Geochemistry Group, the field of interest being noble-gas geochemistry The appointee will work with Dr Ian McDougall, Senior Fellow, in developing research in this field, which is new to the School. The School wishes to make the appointment at the Research Fellow level, but will be prepared to consider applications at the level PDF or SRF

Noble gas investigations are being initiated to assist in elucidation of the geochemical evolution of the mantle, the mantle-crust system, and the atmosphere. Research initially will concentrate on mantle-derived rocks, with subsequent development of studies on fluids in the crustal environment Provision of a suitable high-resolution gas-source mass spectrometer is in hand, and construction of appropriate extraction lines is planned

Persons with suitable backgrounds in the physical sciences, and with particular interests in geochemistry, are encouraged to apply. Experience in noble gas studies on geological samples would be a great advantage.

The appointee will assist in developing the laboratory facilities, and will be expected to undertake discrete projects within this broad field of study. Active collaboration with other workers in isotope geochemistry is envisaged. Enquiries may be directed to Dr I McDougall (062 49 4136).

Closing date: **14 June 1985.** Ref. ES/1.5 1

Faculty of Science
DEPARTMENT OF ZOOLOGY
POSTDOCTORAL FELLOW

The successful applicant will work on a NH & MRC funded project involving gene cloning of sheep parasites particularly larval tapeworms and liver fluke Particular interest will be centred on those genes which code for antigens that are involved either in resistance to reinfection or immunopathological phenomina A principal objective will be to obtain expression of these antigens in prokaryotic systems. Experience in gene cloning techniques is essential and some knowledge of immunological procedures would be highly desirable. The successful applicant will work in the Centre for Recombinant DNA Research, Research School of Biological Sciences (Executive Director· Professor J A Pateman FRS). The position is funded for 3 years. Previous applicants need not reapply as all applications will be considered.

Further information is available from Dr M J Howell, (062) 49 3060 or (062) 49 4225

Closing date: **15 July 1985.** Ref: FS/1 5.1

CONDITIONS OF APPOINTMENT. Salary will be in accordance with qualifications and experience within the range: Postdoctoral Fellow $A21,411-$24,528 pa; Research Fellow $A24,840-$32,634 pa; Senior Research Fellow $A34,699-$41,390 pa Current exchange rate is $A1 00 = Stg 0.48.

Grants are provided towards travel and removal, though special conditions may apply to persons appointed to externally funded positions. Assistance towards housing is given to an appointee from outside Canberra. Eligible appointees will be required to join the Superannuation Scheme for Australian Universities. Maternity leave is available. The University reserves the right not to make an appointment or to make an appointment by invitation at any time **Applicants should quote the advertisement reference when requesting further particulars and when submitting applications, which should be sent to the Acting Registrar of the University, GPO Box 4, Canberra, ACT 2601, Australia. General Information also available from the Secretary General, Association of Commonwealth Universities (Appts) 36 Gordon Square, London WC1H 0PF.**

Connective Tissue Development

A 2-year position is available for studying collagen-proteoglycan interactions in the morphogenesis of the avian corneal stroma The research involves connective tissue biochemistry and electron microscopy. **Further details from Dr J Bard, MRC Unit, Western General Hospital, Edinburgh EH4 2XU, UK.** (6550)A

COMMONWEALTH AGRICULTURAL BUREAUX

Applications are invited for the following posts

DIRECTOR

COMMONWEALTH INSTITUTE OF BIOLOGICAL CONTROL

The Commonwealth Institute of Biological Control, backed by the CAB Information and Identification Services, provides a world service in biological control, giving advice, disseminating information and undertaking research and development projects for sponsors. Although best known for the control of insects and weeds by introduced beneficial insects, its work on the use of microbial agents and the control of other pest organisms by biotic agents is expanding.

It is also collaborating in the development of integrated crop protection with emphasis on biological control. Its research programme is carried out, much of it from strategically situated field stations in Europe, tropical America, Africa and tropical Asia, controlled by a headquarters group at Imperial College, Silwood Park, Ascot, Berks

The appointed officer will be stationed at either Silwood Park or at CAB Headquarters and will be responsible to the Director Scientific Services.

Duties

The Director will promote the Institute's activities, actively seeking research contracts and developing a network of callaborators worldwide. He/She will be an authority on biological control of international standing who will provide scientific leadership and develop the Headquarters group as a centre of excellence. They will also have responsibility for developing the training activities and publications of the Institute. The latter include Biocontrol News and Information, books and data banks

Qualifications

Candidates should have a background of research in biological control with a good publication record, extensive knowledge of pest control in developing countries, experience in research administration and an ability communicate with people from diverse backgrounds.

Salary

The salary will be in the scale £20,013 — £22,283

DIRECTOR

COMMONWEALTH INSTITUTE OF ENTOMOLOGY

The Commonwealth Institute of Entomology is a constituent Institute of the Commonwealth Agricultural Bureaux located at the British Museum (Natural History), where a team of specialists are involved in insect indentification and taxonomic research, and at 56 Queen's Gate, South Kensington, London, which houses the publications office and library. After centralisation of the CAB Information Service, currently being planned, the Institute will operate mainly from the British Museum (Natural History)

The main functions of the Institute are.

(1) To provide an authoritative and efficient world service for the identification of insects and mites of economic imporance to agriculture (including forestry and other related disciplines) and make the information available through its publications and otherwise.
(2) To conduct research on applied taxonomy relevant to the identification services.
(3) To undertake training in taxonomy and identification.
(4) To provide information on the nomenclature, biology, distribution, host ranges and status of pest species and of their associated predator/parasitoid complexes

Duties

The Director will be a working taxonomist and will be responsible for day-to-day running of the Institute and for promoting its activities under the general direction of the Director Scientific Services. He/She will keep in close touch with entomological research organisations in the UK and overseas.

Qualifications

Candidates should have a higher degree in Entomology, a wide knowledge of applied entomology, knowledge of current entomological research and entomological taxonomy as well as experience in administration.

Salary

The salary will be in the scale £16,229 — £18,333 plus Inner London Weighting of £1,300 p.a.

Further particulars of these posts are available from:
Director of Administration Services
Commonwealth Agricultural Bureaux
Farnham House
Farnham Royal
SLOUGH SL2 3BN, UK.

to whom applications, enclosing a curriculum vitae and naming three referees, should be submitted *not later than June 10th, 1985.*

ICRISAT

International Crops Research Institute for Semi-Arid Tropics (ICRISAT)
needs

PLANT PATHOLOGIST
at Bulawayo, Zimbabwe (Southern Africa)

To work in a multidisciplinary team for sorghum and pearl millet improvement in nine Southern African Development Coordination Conference (SADCC) countries. The position will require: development of disease resistance; work with national sorghum and millet programs to develop their own effective capability to deal with disease problems on a continuing basis; and keep a constant vigilance, in a collaboration with national programs, for shifts in disease problems, particularly susceptibilities of promising breeding lines. Candidates must be able to furnish leadership for the establishment of productive research and training linkages with all SADCC countries and work closely with the regional, multidisciplinary team.

Qualifications. Ph.D. in Plant Pathology with sound knowledge and experience of disease resistance and field experimentation, and should be willing to travel frequently and conduct research in the sorghum and millet areas of southern Africa. Excellent command of English is required Tropical agricultural experience and a working knowledge of Portuguese would be an advantage

Salary for the position is at the principal staff level, according to qualifications and experience. The position is contractural with initial 2-year appointment and attractive fringe benefits The post is in Bulawayo, Zimbabwe, a modern city with pleasant surroundings, excellent educational facilities, good medical facilities, and frequent transportation service. Position is one of an eight-member team being assembled for sorghum and millet improvement.

Send resume and names and addresses of three referees within 30 days from the date of advertisement to the Director General, ICRISAT Patancheru, P.O. Andhra Pradesh 502 324, India.

Wolfson Unit
MOLECULAR BIOLOGIST

An additional molecular biologist is required to join a growing research team working on the molecular biology of protozoan and viral agents of human disease. There will be an opportunity to develop personal research interests. Salary, on appropriate scales, and conditions of appointment are negotiable according to experience and age.

Candidates should send full curriculum vitae, naming three professional referees and describing research interests, to the Personnel Officer, London School of Hygiene and Tropical Medicine, Keppel Street, London WC1E 7HT. CLOSING DATE 10 June 1985. (6593)A

MEDICAL RESEARCH COUNCIL
BRAIN METABOLISM UNIT, EDINBURGH
CLINICAL SCIENTIST AT CONSULTANT LEVEL

Applications are invited for a CAREER CLINICAL SCIENTIST post with the Medical Research Council. The post is tenable at this Unit in the first instance. The successful applcant will be an appropriately qualified psychiatrist who has an outstanding backgrond in psychiatric research and has demonstrated the capacity od leading a major programme of clinical research with special emphasis on psychoneuroendocrinology and/or psychopharmacology. An honorary consultant contract will be sought on behalf of the successful applicant whose clinical duties will include responsibilities for the in-patient unit and routine outpatients and emergency duties

The clinical staff of the Unit include 3 other clinical scientists and 1 registrar with facilities on a self-contained Metabolic Ward of 9 beds with access to a further 8 beds in a general psychiatric area of the hospital. The Metabolic Ward is directly linked with the clinical offices and the clinical research suite of the Unit which are housed in a new building at the Royal Edinburgh Hospital The unit pursues an integrated programme of research in clinical and experimental neuroendocrinology, psychoneuroendocrinology, psychopharmacology and nuerophармacology, and has close links with the Departments of Pharmacology and Psychiatry in the University of Edinburgh.

The salary will be in the range £20,200 — £26,080 (Medical Research Council Consultant Grade).

Applications (6 copies), including a detailed curriculum vitae, list of publications and the names of 3 professional referees, should be lodged no later than June 7th, 1985 with the Director, Professor G. Fink, MRC Brain Metabolism Unit, University Department of Pharmacology, 1 George Square, Edinburgh EH8 9JZ, from whom further details about the post may also be obtained. Applicants should include a statement, of about 1,000 words in length, explaining the research programme that they would wish to carry out if appointed. (6429)A

The Biomedical Research Centre
University of British Columbia
Vancouver

Scientific Director

This new research institute established jointly by The Wellcome Foundation Limited, one of the world's major pharmaceutical companies and the Terry Fox Medical Research Foundation, a Canadian charity, will be sited on the campus of the University of British Columbia, Vancouver. The primary focus of its work will be the role of biologically active proteins in the control of cell growth, division and differentiation, with special reference to their evaluation as potential medicinal substances.

The Centre will be closely associated with the University Health Sciences Centre Hospital providing the opportunity to extend the results of basic scientific research to practical application. There will also be access to a pilot fermentation plant and interaction with University programmes will be encouraged.

The Scientific Director will be accountable for the effective utilisation of this custom-built, 35,000 sq.ft. facility, in the fields of scientific research. Leading a team of up to 100 people, with start up funds of Canadian $23m over 5 years, he/she will be responsible for establishing the Centre as a unique venture of international standing.

Candidates must have a record of scientific achievement of a quality which will attract scientists of the highest calibre to the Centre. Experience in an area of cell or molecular biology is essential and a medical qualification would be an advantage. A proven ability to direct or manage in an entrepreneurial environment and a commitment to a practical approach to science will be equally important.

Salary and other benefits will be negotiable and commensurate with the key nature of the post.

The appointment will be made in accordance with Canadian immigration requirements and equal opportunities will be given to male and female applicants.

Applications or nominations are invited by 31st July 1985 and should be forwarded to The Terry Fox Medical Research Foundation, Suites No. 1130-1176, West Georgia Street, Vancouver, British Columbia V6E 4A2, Canada, from where further particulars can be obtained. (NW1784)A

RESEARCH CENTER DIRECTOR

Applications and nominations are invited for a Director, Center for Atmospheric and Biospheric Effects of Combustion, located in the Applied Science Division. The scope of the Center is interdisciplinary and includes four major areas: Combustion and Abatement, Atmospheric Pathways and Chemistry, Radiative Balance, and Ecosystem Pathways and Effects. The Director will coordinate the efforts of a number of scientists, including chemists, physicists, engineers, biologists, geologists, meteorologists, and energy analysts to carry out the objectives of the Center; will be responsible for obtaining research support from governmental and non-governmental organizations; will represent the Laboratory at various related national and international meetings; and will also carry out research within the Center. This position requires a Ph.D., and a record of distinguished leadership, outstanding research accomplishments and an international reputation in one or more of the above areas. Experience and background in program planning, development, implementation, administration and evaluation is required. The incumbent should also have experience in obtaining research funds and have a familiarity with organizations that provide these research funds. Salary will be negotiable. The successful candidate will be appointed a Senior Staff Scientist at the Lawrence Berkeley Laboratory.

Applications and/or nominations should be forwarded to: Lawrence Berkeley Laboratory, One Cyclotron Road, Employment Office 90-1042, Berkeley, CA 94720. Please specify Job A/3330. An Equal Opportunity Employer M/F/H. (NW1777)A

Behavioural Pharmacologist

Roussel Laboratories Limited is part of the international Roussel Uclaf group with extensive interests in pharmaceuticals and associated health-care products. The Swindon research centre is an integral part of the international research organisation with a commitment to the development of new drugs in a number of therapeutic areas.

We seek a Behavioural Pharmacologist to join an established team expanding its research into new remedies for the treatment of central nervous system diseases. Candidates should have a PhD, preferably with one to two years' relevant post-doctoral experience.

Conditions of employment are excellent, including a competitive salary, free life, accident and medical insurance cover, contributory pension scheme and generous assistance with the cost of relocation to this attractive part of Wiltshire.

Further details are available on request, and applications should be made by sending a detailed cv to Rosemary Curtis, Assistant Personnel Manager, Roussel Laboratories Limited, Kingfisher Drive, Covingham, Swindon, Wiltshire SN3 5BZ. Telephone: 0793 24411. Closing date: 21 June 1985.

ROUSSEL

(6609)A

VIRGINIA INSTITUTE OF MARINE SCIENCE
FISHERIES CRUSTACEAN BIOLOGIST

Applications are invited for a tenure track faculty position in fisheries crustacean biology. The position is at the assistant or associate professor level in the Department of Fisheries Science, School of Marine Science (VIMS), College of William and Mary at Gloucester Point, Virginia. Candidates must have a Ph D. in marine ecology, oceanography, or fisheries science Experience is required in crustacean biology, statistics and marine field ecology

The incumbent will be expected to develop and supervise a research program on crustacean biology with initial emphasis on blue crab recruitment, abundance and distribution. The incumbent will also supervise an on-going 30-year monitoring program for collection of data on juvenile blue crab abundance and distribution. Additionally, the incumbent will develop an ecological research program on other crustaceans, including their role in Chesapeake Bay finfish food webs.

VIMS serves as the mandated scientific advisory institution to state and regional fisheries management agencies, and as such the incumbent would be called upon periodically to serve on committees or advise such agencies

The position, in the School of Marine Science, includes contributing to the academic program in the conduct of formal course offerings and direction of graduate student programs and research.

Prior to 1 July 1985, applicants should submit a vitae, statement of research interests, and the names and addresses of three references to: Herbert M. Austin, Chairman, Search Committee, VIMS, Gloucester Point, Virginia 23062.

An EEO/AA Employer. Minorities and women are encouraged to apply.

DEPARTMENT OF BIOCHEMIST

POST-DOCTORAL RESEARCH ASSISTANT

Applications are invited for above post to work on a MRC fun project on the microdissection microcloning of the mouse X-chr osome. The project involves the struction of detailed molecular m of individual regions of the m X-chromosome for the isolation characterisation of interes genetic loci, in particular (X-linked muscular dystrophy). applicant should have experienc recombinant DNA technology.

The post is available immedia Salary is on the 1A scale (star point, £7,520 plus £1,233 pa Lon Allowance) for research staff.

Enquiries to Dr S D M Brow (01) 723-1252 ext 333. Applicat including full cv and names addresses of 2 referees to Assis Secretary (Personnel) at ab address by 31 May 1985. (6534)

MONASH UNIVERSITY
Melbourne, Australia

FOUNDATION CHAIR OF FORENSIC MEDICINE

Applications are invited for appointment to the Foundation Chair of Forensic Medicine. By agreement between the Attorney-General of the State of Victoria and Monash University the Professor will also hold the position of Director of the newly-established Victorian Institute of Forensic Pathology. It is expected that the appointee will take up duty as soon as practicable in 1986 so that the appointee can advise the Council of the Institute on the appointment of professional and technical staff and on further planning of the Institute which it is envisaged will be completed for occupancy in 1987.

Applicants should be medical graduates with qualifications registrable in Victoria and should hold specialist qualifications in Pathology. Applicants should also have extensive experience in the area of Forensic Pathology and be able to provide leadership and direction in the service activities of the Institute and in the teaching and research activities of the University.

Salary: $A64,773 per annum which includes a clinical loading of $A9,825 per annum. Superannuation, travel and removal allowance, and temporary housing assistance.

Information on application procedure and further particulars may be obtained from the Registrar, Monash University, Clayton, Victoria 3168, Australia, or the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF

Applications should reach the Registrar not later than 31 July 1985. Council reserves the right to make no appointment or to appoint by invitation at any stage.

An equal opportunity employer.

INSTITUTE OF CANCER RESEARCH
TECHNICIAN

A vacancy exists in the Institute's Radiotherapy Research Unit at Sutton, Surrey for a Technician to take part in a research project on experimental tumour therapy. The work will involve in vivo and in vitro studies on human tumour xenografts and cell lines, using both radiotheraphy and chemotheraphy. The post would be suitable for graduates in biological sciences or biochemistry, experience in tissue culture would be an advantage Starting salary in range £5,738 — £7,417 pa, plus London Allowance of £623 pa, dependant on age and experience.

Applicants are advised that in the majority of the Institute's premises smoking is prohibited.

Applications in duplicate with the names of two referees to the Personnel Officer, Institute of Cancer Research, 17A Onslow Gardens, London SW7 3AL, quoting Ref 01/B/88 (6571)A

Environmental Chemist

Negotiable salary + car

The Burmah Group is a major British industrial enterprise with a turnover of £1.7 billion. Our wide-ranging activities include oil exploration and production, the marketing of lubricants and fuels, speciality chemicals, shipping, and an investment division.

Reporting to the Group Environmental Officer, you will be responsible for obtaining and analysing occupational hygiene samples to ensure employees are not exposed to chemical harm. In addition to operating a monitoring programme and developing new analytical methods, you will set up and run a computerised archiving system.

You should have a good chemistry degree and some years' industrial experience. Self-motivated with the ability to tackle the unknown, you must be an able communicator at all levels. A willingness to travel extensively to Burmah sites spread throughout the UK is essential. An understanding of microcomputers and programming ability would be an advantage.

A competitive salary is accompanied by attractive large-company benefits including a car.

Please send a full cv, or ring or write for an application form to Mr R J Doncaster, Recruitment Officer, Burmah Oil Trading Limited, Burmah House, Pipers Way, Swindon, Wiltshire SN3 1RE.

Burmah

M.R.C. CLINICAL RESEARCH CENTRE
(NORTHWICK PARK HOSPITAL)
WATFORD ROAD, HARROW
MIDDLESEX HA1 3UJ

TECHNICIAN

A vacancy exists within our Divison of Immunochemical Genetics for a Technician.

The work of the division is concerned with the molecular basis and genetic regulation of carbohydrate antigens and exemplified by certain of the human blood group antigens.

The successful applicant will be required to assist in the production of monoclonal antibodies, genetic complementation, and gene clonings experiments. Previous experience in any of these areas would be an advantage, but a good grounding in tissue culture techniques is essential.

Applicants should have a degree, HNC or equivalent in a Biological subject. Salary will be on a scale £6,361 — £8,719 inclusive of London weighting, depending on qualifications and experience.

Applicants should apply to Miss B A Shaw, Personnel Section, quoting reference: 131/2/4290. Closing date: 14th June 1985.
(6606)A

MOLECULAR BIOLOGIST/ BIOCHEMIST:

Applications are invited from post doctoral scientists to join a multidisciplinary team investigating the mechanism of carcinogenesis in mouse and human epithelial cells. Main research interests are oncogene transfection of keratinocytes, alterations in cell genotype/phenotype and regulation of epidermal differentiation by mesenchymal factors at different stages of malignant transformation. The candidate must hold a PhD in Biochemistry, Molecular Biology or Molecular Genetics and have a strong interest in Cell Biology and Molecular Genetics. Experience with recombinant DNA techniques, cellular transfection and in situ hybridisation would be advantageous. Excellent research facilities are provided and the position is available from July 1985 for 1½ years in the first instance with a possibility of further prolongation. The salary will be in the range 30,000 — 50,000 DM per annum depending on age and experience.

Applications including curriculum vitae, research experience and interests, list of publications and the names of two referees should be sent to German Cancer Research Centre (DKFZ), Personalabteilung, Im Neuenheimer Feld 280, D-6900 Heidelberg, FRG.

For further information ring Prof. N.E. Fusenig: country code and 06211-484507. (W1874)A

Assistant Agronomist
Sudan

An Assistant Agronomist is required to supervise all crop research activities in the Yei district of Southern Sudan, together with conducting surveys on the agronomic problems and constraints in agricultural production with a view to establishing an adaptive on-farm research programme.

Responsibilities will also include establishing crop storage experiments, participating in the technical agronomy programme together with the supervision of sub-stations and assisting in the analysis of data.

Applicants should be British Citizens with a post graduate degree or diploma in Tropical Agronomy, with three to seven years experience of handling grain legumes, preferably in a humid tropics environment. Experience in on-farm trials with smallholder farms is desirable.

The appointment is on contract to ODA on loan to the Government of Sudan for a period of two years. Salary (UK taxable) is in the range £13,650 to £17,150 pa, which includes an element in lieu of superannuation. A variable tax-free Foreign Service Allowance, currently in the range £4,520 to £9,085 pa, is also payable.

The post is wholly financed by the British Government under Britain's programme of Aid to the developing countries. Other benefits normally include paid leave, free family passages, children's education allowances, free accommodation and medical attention.

For full details and application form, please apply, quoting ref. AH309/AF/N, giving full details of age, qualifications and experience to: Appointments Officer, Overseas Development Administration, Room 351, Abercrombie House, Eaglesham Road, EAST KILBRIDE, Glasgow G75 8EA. (6556)A

Britain helping nations to help themselves

CROP PHYSIOLOGIST POSITION

The Department of Agronomy and Range Science invites applications for an Assistant or Associate Professor/Assistant or Associate Agronomist position at the University of California Agricultural Experiment Station, Davis, CA. Research interests should focus on whole plant physiology processes that relate to agronomic crop performance in California. The candidate will be expected to develop an active research program which complements existing multidisciplinary efforts. Teaching duties will include a graduate course in crop physiology/ecology and participation in graduate seminars on a rotating basis. Advising duties will be in an appropriate discipline. A Ph.D. in plant physiology or related field is required. The level of appointment will be commensurate with the candidates experience. Recent graduates are especially encouraged to apply. **Send a statement of research interests, curriculum vitae, transcripts and the names and addresses of *three* references by August 15, 1985 to: R.L. Travis, Search Committee Chairman, Department of Agronomy and Range Science, University of California, Davis, CA 95616. Phone: (916) 752-6187 or (916) 752-1703.**

The University of California is an Affirmative Action/Equal Opportunity Employer. (NW1780)A

UNIVERSITY OF BIRMINGHAM
Faculty of Medicine and Dentistry
DEPARTMENT OF PHYSIOLOGY

Applications invited to work on the mechanisms of insecticide resistance by studying nerve insensitivity to pyrethroids and DDT in genetically designed strains of house-fly. The work will be carried out under the supervision of Dr M P Osborne in collaboration with Rothamstead Experimental Field Station.

The post is for three years from 1.10.85, financed by the Agricultural and Food Research Council. Salary Grade IB £6,600 - £7,520 with superannuation.

It is expected that the appointed person will have a Good Honours Degree in some aspects of Biological Sciences with a special interest in Neurophysiology and/or Entomology. Suitably qualified candidates will have the opportunity to register for a PhD.

Enquiries to Dr M P Osborne, Department of Physiology, Medical School, University of Birmingham B15 2TJ. Telephone 021-472 1301, ext 3350.

Applications (three copies) to Assistant Registrar, Medical School, University of Birmingham B15 2TJ, by 10.6.85. Quote reference RA/Phy/MO. (6580)A

UNIVERSITY OF GLASGOW
DEPARTMENT OF PATHOLOGY
WESTERN INFIRMARY

A PhD graduate with 3 years post-doctoral research experience in protein chemistry is required for a three year Arthritis and Rheumatism Council project grant in the University of Glasgow. The aim of the project is to isolate and characterise a plasma protein which interferes with the complement-mediated solubilisation of antigen-antibody complexes. Salary starts at point 4 on the University scale 1A. Applications with CV and names and addresses of two referees to Professor K Whaley, Department of Pathology, Western Infirmary, Glasgow G11 6NT by June 14th 1985. (6597)A

UNIVERSITY OF CAMBRIDGE
COLLEEN MACLEOD PROFESSORSHIP OF ANIMAL WELFARE

Applications are invited for this newly established Chair.

Present pensionable stipend £20,995.

Applications (10 copies) marked 'Confidential' should be sent to the Secretary General of the Faculties, from whom further information may be obtained, at the General Board Office, The Old Schools, Cambridge, CB2 1TT. Names of two referees may be submitted is desired.

Closing date 7th June 1985. (6557)A

UNIVERSITY OF NOTTINGHAM
DEPARTMENT OF METALLURG AND MATERIALS SCIENCE
RESEARCH ON DIFFUSIC IN THIN OXIDE FILMS

A postdoctoral appointment for th years is available for study of dif sion processes in the formation of t oxide films. The technique which volves the use of radon atoms Kirkendall markers, has been appl to anodic oxide films and recent i provements have shown that it is s ficiently sensitive and precise for it be applied to the passive films, tarn films and other low temperature, th mally activated film growth proces

The investigations are relevant i only to oxidation and corrosion p cesses but to the generation of ox films for integrated solid state el tronic devices. The technique is available elsewhere in Europe a funds are available for the impro ment of the present equipment. T programme includes an element collaboration with research work in Paris who are using complement techniques for the study of simi phenomena.

Applications are invited fr suitably qualified people. Please w or telephone Professor J S L Lea Department of Metallurgy a Materials Science, The University Nottingham, University Park, N tingham, NG7 2RD. Tel 0602 506 ext 2116. (657

UNIVERSITY OF SOUTHAMPTON
CHAIR OF OCEANOGRAPHY

Applications are invited for the Ch of Oceanography which will beco vacant on the retirement of Profes H Charnock, FRS, on 30 Septem 1986. Applicants should ha research interests in the physical related marine sciences and ability to foster work in a mu disciplinary field.

Further details may be obtair from the Secretary and Registr The University, Southampton, S 5NH, to whom applications copies from persons in the U should be sent before 12 July 198 (6524)A

IMPERIAL COLLEGE
London SW7 2AY
DEPARTMENT OF CHEMISTRY
POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a po doctoral research assistant for newly created Imperial Coll colloid and interface group to w with Drs M H George and J A Bar on the immobilisation of enzymes catalysis in copolymer micell Previous experience in orga synthesis and/or polymer chemis would be desirable.

Applications should be sent soon as possible to Dr M H Geor Department of Chemistry, Imper College, London SW7 2AY. (6594)A

ASSISTANT PROFESSOR, BIOCHEMISTRY

Applications are invited for one 12-month, tenure-track position which will begin on or before 1 January 1986 Preference will be given to individuals with chemical and biochemcal expertise and research interests in the structure-function relationships of biological macromolecules. Despite these preferences, application from individuals having other research interests and expertise will be considered. Applicants, who should have a Ph.D and postdoctoral experience in biochemistry or a related field, will be expected to develop an active, externally funded research program, and to participate in the undergraduate and graduate teaching programs of the department Normal teaching assignments are a one semester lecture or laboratory course per academic year. Applicants should include curriculum vitae, copies of publications, graduate and undergraduate transcripts and a brief statement of current, and future research interests. Three people, well acquainted with the applicants's research and teaching ability, should be asked to send letters of reference. Review of applications will begin in June 1985; interviews will be scheduled in late summer or early fall 1985. Inquiries and applications should be directed to. **Roger E. Koeppe, Biochemistry Department, 454 PSII, OKLAHOMA STATE UNIVERSITY, Stillwater, Okla. 74078.** *Equal Opportunity/Affirmative Action Employer.* (NW1769)A

Scientists for Research into Arthritis

The Boots Company PLC has, at its Nottingham Headquarters, a well-established research group concentrating on the identification and development of more effective drugs to treat arthritic diseases.

Continuing growth in this major research field has created the need for two more Research Scientists to join our team. There is considerable challenge — playing a key role in the development and implementation of novel experimental models which simulate chronic inflammation in humans.

You should have a Degree in biochemistry, cell biology or pharmacology with a relevant PhD or three years research experience. You will find wide scope for your initiative in these rewarding posts, with excellent opportunities for career growth.

We are offering a range of benefits expected of a large Company, including profit sharing, contributory pension and staff purchase schemes. Generous relocation assistance will be available where applicable. (6601)A

Please write, with full career details, to: T. W. Flower, Employment Manager (Technical), The Boots Company PLC, Station Street, Nottingham NG2 3AA. Telephone (0602) 506255. Ext. 243.

The Boots Company PLC

THE DEPARTMENT OF PEDIATRICS, University of California, San Diego, Division of Pediatric Immunology and Allergy, has an opening for a **FACULTY MEMBER** with a special interest in clinical immunology/allergy, with research experience in neonatal immunology and cellular aspects of allergic disease. Preferred experience in Pediatric Intensive Care Unit. This position will be at the level of Assistant Professor. Position includes clinical supervision and teaching of housestaff and medical students. Applicants should be board certificate or board eligible in pediatrics, experience in teaching and clinical service; with research background. Salary commensurate with skills, knowledge, and University of California policy. Candidates apply by June 1, 1985 with C.V. to Robert N. Hamburger, M.D., Professor of Pediatrics, Department of Pediatrics, UCSD, M-009-D, La Jolla, CA 92093. EEO/AA. (NW1783)A

DEPARTMENT OF BIOLOGY YORK UNIVERSITY

Applictions are invited for a tenure track position as Assistant Professor in Population Biology (Animals or Plants) or Behavioural Ecology. Applicants must have demonstrated a strong potential in some area of ecological research. In accordance with Canadian Immigration Requirements, this advertisement is directed to Canadian citizens or permanent residents. **Applications, including a curriculum vitae, recent reprints and names of at least three referees should be sent to Professor A.S.M. Saleuddin, Chairman, Department of Biology, York University, 4700 Keele Street, 246 Farquharson Building, North York, Ontario M3J 1P3. Closing date is December 31, 1985 or when the position is filled.** (NW1773)A

UNIVERSITY OF WISCONSIN-MADISON AQUATIC BOTANIST

RESEARCH ASSOCIATE (postdoctoral) position available by 1 June, 1985, for laboratory and lake studies on integrated control of Eurasian watermilfoil and impact of control strategies on water quality. Additional experience in water chemistry, limnology, or mycology desirable. Funding for two years. Salary competitive and commensurate with qualifications

Send résumé, including the names of three referees, to: Dr. John H. Andrews, Department of Plant Pathology, 1630 Linden Drive, Madison, Wisconsin 53706.

An affirmative action-equal opportunity employer (NW1781)A

RESEARCH POSITION IN MOLECULAR/CELL BIOLOGY

Post-doctoral, Assistant or Associate Research Professor level position are available starting immediately in the Department of Cell Biology. The person/s appointed will be member of a research group investigating the role of oncogenes, their possible interactions with carcinogens in normal and HBV-infected hepatocyte transformation in culture or *in vivo*

Applicants should have experience or knowledge in the following areas: general cell culture techniques; recombinant DNA techniques; virology

Salary is negotiable and will be based upon the candidate's previous training and experience (BAT IIA — BAT IA). Permanent positions will be made available to persons with the appropriate background.

Send CV and names of 2 referees before 13 June 1985 to: Prof. Dr. Dieter Paul, Institut of Toxicology, University Hamburg Medical School, Grindelallee 117, 2000 Hamburg 13 Federal Republic of Germany. (W1871)A

FhG

DIRECTOR OF FOOD RESEARCH

£26,909 (Under Review)

Applications are invited for the post of Director of Food Research. The person appointed will be directly responsible to the Secretary to the AFRC for the control, development and management of research at the Council's Food Research Institute at Bristol, Norwich and Reading The Director will be required to contribute more widely to the continuing development of a food research strategy for the Agricultural and Food Research Service.

The post will be based initially at one of the Institute sites where the Director will be supported by a small administrative team

Candidates should be highly qualified in food science or the related underpinning sciences, with a distinguished record in research, a knowledge of the food industry and considerable experience, at a senior level, in the management of research. Non-contributory pension scheme. The successful applicant may qualify for assistance with removal expenses

The AFRC is an Equal Opportunity Employer.

Further particulars and application forms can be obtained from John Pettinger on 01-580 6655 (Ext 244). Completed applications should be returned by 21 June 1985 to Mr J M Y Dickens, Chief Personnel Officer, AFRC, 160 Great Portland Street, London W1N 6DT.

(6537)A

MRC IMMUNOCHEMISTRY UNIT
Associated with DEPARTMENT OF BIOCHEMISTRY UNIVERSITY OF OXFORD

MOLECULAR IMMUNOLOGIST

Applications are invited for a short-term non-clinical scientific post at postdoctoral level tenable for 3 or 5 years in this MRC Unit.

The project to be investigated would be subject to discussion with the successful applicant, but would be concerned with the application of protein chemistry and recombinant DNA techniques within the general field of effector mechanisms in immunity and autoimmunity.

The appointment will be from 1 January, 1986, or later by arrangement.

Remuneration will be at an appropriate point on the scale for University non-clinical academic staff. **Further information may be obtained from Professor R. R. Porter, F.R.S., Department of Biochemistry, South Parks Road, Oxford OX1 3QU (Telephone: 0865-56733), to whom applications should be sent by 5 July. Ref: BC/129.** (6576)A

PLANT GENE TECHNOLOGY and DNA RESEARCH

POSTDOCTORAL POSITION

Candidates with a background in plant physiology and/or DNA research are invited to join an industry-funded independent research group at the Institute of Molecular Biology of the Austrian Academy of Sciences in Salzburg.

We offer a salary and benefits commensurate with experience according to Austrian Academy of Sciences scheme. The initial appointment will be for one year with possible extention up to four years. Resume, list of publications and three letters of reference should be submitted to CHEMIE LINZ AG, Personalwirtschaft, POB 296, A 4021 Linz, Austria.

Nous sommes l'un des tout premiers groupes pharmaceutiques mondiaux et nos activités en France sont en forte croissance

Pour renforcer le potentiel technique et de créativité de notre Centre de Recherche situé à RENNES nous créons de nouveaux postes

Pharmacologue Cardiovasculaire

Au sein du département **Biologie** et en synergie avec les autres chercheurs et techniciens du centre :

- vous concevrez et mettrez au point les modèles " Physiopathologiques " et " thérapeutiques ".
- vous réaliserez et suivrez les études et travaux sur le métabolisme myocardique.

Vous possédez une formation universitaire en Pharmacie ou Sciences (Physio) et un doctorat en Sciences Biologiques et une expérience d'au moins 3 ans en pharmacologie dans le domaine cardiovasculaire.

Chimiste Organicien

Au sein du département **Chimie** et en synergie avec les autres chercheurs et techniciens du centre :

- vous concevrez et réaliserez la synthèse de nouvelles molécules thérapeutiques dans le domaine cardiovasculaire
- au vu des résultats pharmacologiques, vous optimiserez les structures explorées.

Vous possédez une formation de type ENSC (option chimie organique) et un doctorat (chimie organique et / ou thérapeutique) et une expérience d'au moins 3 ans en synthèse (chimie thérapeutique) dans l'industrie pharmaceutique ainsi que des connaissances en méthodes de " Drug Design ".

L'environnement international du groupe vous permettra d'évoluer et implique la connaissance de l'anglais.

Merci d'adresser votre candidature sous réf. 770 M en indiquant le poste souhaité à J.M. REMY- C.R.E.S.
4, rue du Chesnay - Beauregard BP 45 35760 SAINT-GREGOIRE (W1888)A

Beecham pharmaceutique

laboratoires SOBIO

UNIVERSITY OF DURHAM
INDUSTRIAL RESEARCH LABORATORIES

Applications are invited for the following one years post available from dates to be arranged.

SENIOR EXPERIMENTAL OFFICER

To work on the synthesis and characterisation of polymers. Applicants should have a strong background in synthetic polymer chemistry and have experience with standard physicochemical techniques used for polymer characterisation.

SENIOR RESEARCH ASSISTANT

Postdoctoral Senior Research Assistant in polymer synthesis and characterisation for work on the synthesis of co-polymers for use in the manufacture of toner particles. Applicants should have experience in synthetic organic chemistry and familiarity with polymer synthesis is desirable but not essential.

The projects will be undertaken in collaboration with a leading international company. Salaries in the range (under review) £7,520 – £12,150 with superannuation.

Applications (three copies) naming three referees should be sent by 15 June 1985 to the Registrar, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars are available. (6568)A

UNIVERSITY OF ABERDEEN
DEPARTMENT OF MICROBIOLOGY

MICROBIOLOGICAL CORROSION

Applications are invited for two posts to carry out a research programme into the mechanisms and importance of microbial corrosion in seabed sediments.

The two posts are:

1 POST DOCTORAL RESEARCH FELLOW

with a PhD or equivalent industrial experience in corrosion science, preferably with experience of cathodic protection and corrosion monitoring.

2 RESEARCH ASSISTANT

with a degree, or equivalent experience, in microbiology or a related subject; experience in microbial corrosion would be an advantage.

Appointment will be made with immediate effect and will be for two years.

Salaries within range £6,600 – £9,860 per annum on the Range IA or IB scales for Research and Analogous Staff with placement according to experience.

Further particulars and application forms from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by 14 June 1985. (6519)A

MOLECULAR NEUROBIOLOGY IN SWITZERLAND

POST DOCTORAL POSITION

The Molecular Biology Department of Hoffmann-La Roche Inc., Basle Switzerland has an opening for a post-doctoral fellow to perform basic research on the genetic basis and regulation of:

NEUROTRANSMITTER RECEPTORS AND ION CHANNELS

The department (Director Dr. H. Bujard) offers an excellent research environment and the opportunity for interaction with many research laboratories in molecular biology, neurobiology, electrophysiology and pharmacology. The position is available from July 1985 for 1-2 years. Costs of moving to and from Basle will be covered. Salary conforms with the Swiss National Science Foundation standards.

Applicants should submit a curriculum vitae and a statement of research activities to Dr. H. Mohler, Prof. of Biochemistry, Research Department, Building 70, Hoffman-La Roche, 4002 Basle, Switzerland. Phone 061/27/6202. (W1879)A

Faculty Position in Neurophysiology

Brain Research Institute, Zürich

The Brain Research Institute, University of Zürich, invites application to a tenured faculty position at the full professor level (Extraordinariat). Preference will be given to candidates with a strong research record in vertebrate system physiology at the single neuron level. The candidate is expected to interact with other neuroscience research groups at the Medical Faculty, particularly those studying neurotransmitters and developmental biology. Some teaching in neurophysiology courses for medical students is required. The candidate should acquire proficiency to teach in German within one year.

Send curriculum vitae, including a synopsis of past research experience, and a statement of research objectives to the Chairman of the Search Committee, Dr. V. Henn, Neurological Clinic, University Hospital, 8091 Zürich, Switzerland. Deadline August 15th. (W1886)A

N.S.W. STATE CANCER COUNCIL
SENIOR RESEARCH SCIENTIST

Applications are invited for the position of Senior Research Scientist within the Carcinogenesis Research Facility, N.S.W. State Cancer Council in the school of pathology, University of N.S.W. the Carcinogenesis Research Facility is a newly founded research laboratory intending to study cellular and molecular aspects of chemical carcinogenesis.

Scientists with strong credentials for, and commitment to, developing and independent research programme in the molecular biology or biochemistry of chemical carcinogenesis are invited to apply. Candidates interested in combining genetic and molecular approaches to the study of neoplastic cells, in gene expression/regulation as it relates to carcinogensis, or in macromolecular changes induced by chemical carcinogens will be given preferential consideration. Applicants must have appropriate qualifications, a record of research publications and experience in establishing an independent research programme.

The post is available immediately and has an annual salary within the range $29,826 to $34,779 p.a. The appointment is for 5 years in the first instance. Consideration will be given to assistance with costs involved in relocation to Sydney.

Interested applicants should submit a full curriculum vitae, list of publications, brief statement of research interests and the names of 3 references to:-

Dr. Gordon C. Hard
Head, Carcinogenesis Research Facility
N.S.W. State Cancer Council
School of Pathology
University of NSW
PO Box 1
Kensington NSW 2033

Applications close on 30th June, 1985. (W1887)A

LUDWIG INSTITUTE FOR CANCER RESEARCH (LONDON BRANCH)

Haddow Laboratories,
Clifton Avenue,
Sutton, Surrey SM2 5PX

THREE YEAR APPOINTMENT
RESEARCH ASSISTANT

is required to work in a group studying the processes of growth, differentiation and neoplastic cell formation in cultured mammary gland epithelial cells. The successful candidate will assist in the first instance in determining the alterations in growth control that allow benign mammary epithelial cells to become malignant. Previous experience with sterile techniques in tissue culture and/or microbiology are essential and prior knowledge of protein purification and/or molecular transfection techniques would be advantageous. Salary will be in the range of £5,738 — £8,492 pa plus £623 pa London Weighting, depending on previous relevant experience.

Applications with details of career and two referees should be sent to the Administrator, at the above address no later than 31st May, 1985. (6533)A

UNIVERSITY OF NEWCASTLE UPON TYNE
CANCER RESEARCH UNIT
RESEARCH ASSOCIATE/ SENIOR RESEARCH ASSOCIATE

Applications are invited from graduate or post-doctoral scientists to work on a research project investigating the activation of oncogenes in cancer progression financed by a grant awarded by the North England Cancer Research Campaign. The Cancer Research Unit has already interest in the relationship of DNA repair to cancer matastasis and in the cloning of DNA repair genes. Collaborative efforts will be encouraged. Candidates should have experience in recombinant DNA techniques. Additional experience in cell biology would be an advantage. The post is available for three years. Commencing salary according to qualifications and experience on Range IA scale £7,520 — £12,150 or up to £13,625 on Range II scale £11,205 — £14,925.

Applications giving a full curriculum vitae and names of three referees should be submitted to Dr G V Sherbet, Cancer Research Unit, Royal Victoria Infirmary, Newcastle upon Tyne NE1 4LP, not later than Friday, 21st June 1985. (6531)A

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY
DEPARTMENT OF AERONAUTICS

RESEARCH ASSISTANT

A Research Assistant is required to conduct a study of the flow in the wake of lowflying aircraft. The work will include experiments which will be performed in the larger wind tunnels in the department. The theoretical aspects of this research will be concerned with modelling the vortex patterns in the wake and predicting the flow produced by the aircraft close to the ground

Applicants should have a good degree in a relevant subject and experience of wind tunnel or related research. The salary will be in the range £7,520 — £12,150 pa (Under review) plus London weighting £1,233.

Further details can be obtained from Dr J K Harvey, Department of Aeronautics, Imperial College, London SW7 2BY, to whom applications should be sent. (6604)A

UNIVERSITY OF LONDON INSTITUTE OF NEUROLOGY

Applications are invited for a post-doctoral position available for up to 4 years in a group investigating transmitter amine metabolism in the freely moving rat by new techniques and studying relationships and finding to milieu, feeding, receptors and behaviour

Applicants should have expertise in relevant aspects of experimental psychology and be interested in neurochemistry and/or pharmacology

Initial salary within range £8,376 — £10,611 (including London Weighting).

Apply with CV and names of two referees to: Professor G Curzon, 33 John's Mews, London WC1N 2NS within a month of the appearance of this advertisement. (6536)A

SYDNEY — AUSTRALIA
THE UNIVERSITY OF NEW SOUTH WALES
SCHOOL OF ANATOMY

RESEARCH OFFICER (REF.220)

The appointee will work under the supervision of Associate Professor J Stone on the development of mammalian retina Applicants should have a PhD or equivalent. A background in Neuroanatomy, Neuroimmunology, Neurophysiology or Neuroembryology would be an advantage. The position is available initially for one year from early January 1986, with prospects of renewal for a further year.

Further information from Associate Professor Stone — (02) 697 2471.

Salary: $A22,614 — $A25,905.

Please submit written application to the General Staff Office, PO Box 1, Kensington, NSW, Australia 2033, by August 2 1985

Equality of employment opportunity is University policy. (W1881)A

UNIVERSITY OF LEEDS
DEPARTMENT OF BIOCHEMISTRY
PROTEIN SEQUENCING FACILITY

Applicants are invited for a post of Post-Doctoral Research Fellow in the above department to assist in the day-to-day operation of the sequencing facility and participate in research work. Knowledge of automated sequencers would be an advantage. Applicants should have a PhD or equivalent experience in a relevant area.

The post is available for a fixed term of up to four years.

Salary on the IA Range for Research and Analogous Staff (£7,520 — £12,150)(under review) according to age, qualifications and experience.

Informal enquiries may be made to Dr J B C Findlay (Tel 0532 431751 ext 7180).

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT quoting reference no 83/61. Closing date for applications 13 June 1985. (6563)A

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF IMMUNOLOGY

Applications are invited for the post of

RESEARCH ASSISTANT

in the Department of Immunology to work with Dr Peter Stern on the molecular genetics of MHC Class-I products expressed by human teratocarcinoma cells. At least a basic knowledge and experience of modern recombinant DNA techniques would be advantageous. The initial salary within the range £6,600 - £7,980 per annum

Applications, together with the names of three referees, should be received not later than 24 June, 1985, by The Registrar, The University, PO Box 147, Liverpool L69 3BX from whom further particulars may be obtained.

Quote Ref: RV/289/N. (6587)A

POSTDOCTORAL/RESEARCH ASSOCIATE Position available immediately for studies of nuclear structures and functions. One (1) project involves primary transcripts, heterogeneous nuclear RNA and small nuclear RNA. The other deals with the identification and characterization of the genes of the blood group antigens. Background in biochemistry, molecular biology and DNA Recombinant Technology is essential. Applicant will join in active research program in Recombinant DNA Technology. Job security with opportunity for advancement, competitive salary, excellent benefits Send Curriculum Vitae and letters of reference to Dr Oscar Pogo, Head, Department of Cell Biology, Kimball Research Institute, New York Blood Centre, 310 E 67 St, New York, NY 10021. Equal Opportunity Employer (NW1753)A

ST MARY'S HOSPITAL MEDICAL SCHOOL
(University of London)
Norfolk Place, London W2 1PG

BIOCHEMISTRY DEPARTMENT

PhD

MRC funded PhD place available to work with Dr John Hardy on neurotransmitter release and uptake by preparations from post mortem human brain. Many neurological and psychiatric disorders are thought to involve specific defects in neurotransmission.

The purpose of this project will be to study various aspects of neurotransmitter release and uptake in post mortem tissue. Specifically, isolated nerve endings (synaptosomes) will be prepared and used to study the distribution of the different transmitter uptake systems in the human brain. Many clinically prescribed drugs are thought to have their actions of modulating neurotransmitter uptake and release by human brain synaptosomes will be examined.

Enquiries to Dr John Hardy. Tel 01-723 1252 ext 117. Applications in the form of a cv with the names and addresses of two referees to the Assistant Secretary (Personnel) at above address by 3 June 1985. (6573)A

DURHAM UNIVERSITY

DEPARTMENT OF GEOLOGICAL SCIENCES

LECTURESHIP IN GEOPHYSICS

Applications are invited for a Lectureship in Geophysics tenable in any area of solid-earth geophysics, but with some preference for candidates in marine geophysics or seismology.

Applicants must have previous research experience in geophysics.

It is hoped to fill the post from not later than 1 October 1985.

Salaries on the scale £7,520 — £14,925 p.a with superannuation.

Application (3 copies) naming three referees should be sent by 31 May 1985 to the Registrar, Science Laboratories, South Road, Durham DH1 3LE. From whom further particulars maybe obtained. (6529)A

MEDICAL RESEARCH COUNCIL LABORATORIES THE GAMBIA

VIROLOGIST

For the MRC Laboratories, Fajara, The Gambia. You will join a team embarking on a study of acute respiratory infections in Gambian children and will be responsible for viral isolations and identifications. Previous experience of respiratory virus isolation is required and more general experience in microbiology would be an advantage. An initial contract of 2 years will be offered which may be renewed. Salary will be determined by qualifications and experience.

Application forms and further details may be obtained from Miss K S Douglas, MRC, 20 Park Crescent, London W1N 4AL. The closing date for applications is 28 June 1985. (6579)A

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
(University of London)

DEPARTMENT OF NEUROLOGICAL SCIENCE

GRADUATE RESEARCH ASSISTANT

(preferably a cellular immunologist) required from 1 September 1985 to help run a fluorescence-activated cell sorter (FACS) in a largely MRC-funded human cellular immunology group. There is some routine analytical and maintenance work, and considerable scope for functional studies on FACS-purified cells in culture. Simple engineering/electronic skill/interest an advantage (but not essential) for this challenging post which is initially available for one year with very good prospects of renewal for a further five.

Salary on scale £6,600 - £12,150 plus £1,233 London Allowance, according to qualifications and experience.

Further details available from School Office, Room G650, RFHSM, Rowland Hill Street, London, NW3 2PF, (01-794-0500 Extn 4262) to which full curriculum vitae and names and addresses of 2 referees should be sent by 7 June 1985. Please quote reference JND/GRA. (6527)A

UNIVERSITY TÜBINGEN FRG

POSTDOCTORAL CO-WORKER

We are looking for a postdoctoral coworker in the field of molecular mechanisms of infection immunity.

Apply to W G Bessler, Arbeitsbereich Immunologie der Universitat, D7400 Tübingen, FRG (W1876)A

AFRC — FOOD RESEARCH INSTITUTE - BRISTOL
Langford, Bristol BS18 7DY

SCIENTIFIC OFFICER

Applications are invited for the post of Scientific Officer (Band II) to join the Hygiene Section and participate in research on the incidence, origin and behaviour of food-spoilage and food-poisoning microorganisms associated with the processing of poultry-meat products.

The work will include both factory surveys and laboratory studies involving the isolation and identification of relevant organisms and investigation of their properties.

Qualifications: Degree in microbiology or HNC with relevant post-qualifying experience.

Salary: £5,909 - £8,153 pa.

Application forms from the Personnel Officer at the above address. Please quote reference no 85/5.

The Agricultural and Food Research Council is an equal opportunities employer. (6592)A

PHILIPPS-UNIVERSITÄT MARBURG

Im fachbereich Humanmedizin in der Humangenetik mit humangenetischer Poliklinik ist zum Herbst 1986 eine

Professur (C4)

für Humangenetik
(Nachfolge von Herrn Prof. Dr. Wendt)

zu besetzen.

Für den Stelleninhaber ist die Leitung der ersten Abteilung in einem neu zu gründenden Zentrum für Humangenetik vorgesehen Nach Berufung soll eine C3 — Professur für die zweite Abteilung ausgeschrieben werden. Außerdem ist ein Funktionsbereich fur klinische Cytogenetik und Pränataldiagnostik als zentrale Einrichtung vorgesehen.

Gem. Erlaß des Hess. Ministers fur Wissenschaft und Kunst ist alternativ offenzuhalten, daß die Humangenetik in das Zentrum fur Frauenheilkunde und Geburtshilfe oder in das Zentrum fur Kinderheilkunde organisatorisch eingebunden wird.

Der Bewerber soll auf einem aktuellen Forschungsgebiet der Humangenetik international anerkannt sein und über eigene Erfahrungen mit molekulargenetischen Techniken verfügen. Es wird erwartet, daß die Fortführung der klinischen Genetik auf dem in marburg erreichten hohen Niveau gewahrleistet bleibt.

Fur die Ernennung zum Professor sind grundsätzlich padagogische Eignung und-als Nachweis der Befähigung zu wissenschaftlicher Arbeit — neben der Promotion die Habilitation oder gleichwertige wissenschaftliche Leistungen erforderlich. Im übrigen gelten die Einstellungsvoraussetzungen des § 39 a HUG.

Berwerbungen mit den üblichen Unterlagen (das Schriftenverzeichnis ist nach Originalarbeiten, Übersichtsartikel und Fallstudien zu gliedern Bei gemeinschaftlichen Veroffentlichungen soll der Bewerber ausführen, worin seine Miturheberschaft besteht) sind bis zum 30.6.1985 zu richten an den Präsidenten der Philipps Universität Marburg, Beigenstraße 10, D 3550 Marburg.

POSTDOCTORAL POSITION
Massachusetts General Hospital/
Harvard Medical School

2-3 year position available immediately to study regulation of transcription of mammalian genes by hormonal and other factors. Particular focus on interaction of glucocorticoid receptor with DNA and transcription factors. preference will be given to applicants with strong background in molecular genetics, including experience with standard techniques of molecular biology. **Send curriculum vitae and three letters of reference to: Dr D D Moore, Dept. Molecular Biology, Wellman Building, Massachusetts General Hospital, Boston, Ma. 02114.**
equal opportunity/affirmative action employer (NW1774)A

ST. GEORGES UNIVERSITY SCHOOL OF MEDICINE

St. George's University School of Medicine, Grenada seeking additional faculty for the following subjects:

BIOCHEMISTRY PHYSIOLOGY
PHARMACOLOGY NEUROANATOMY
HISTOLOGY PATHOLOGY

Applications from both recent graduates and PhD or MD or more mature individuals. Those taking early retirement may find a period in the Caribbean attractive.

For histology and pathology young recent graduates PhDs or MDs who would like Caribbean environment for a year or two Positions are demonstrators. We wish to fill some positions next August, others New Year.

Return tourist air fare paid for appointee and wife

For further info apply to:

The Vice Chancellor,
849 Lullwater Parkway,
Atlanta,
GA 30307.
United States of America.
Tel: 404-378-0104. (W1873)A

AFRC INSTITUTE FOR RESEARCH ON ANIMAL DISEASES

The Institute has a programme of research into infectious diseases of cattle and pigs. Two "New-Initiative" appointments, each of 3 years duration, have become available within the programme.

(1) MOLECULAR BIOLOGIST

Required to join a team carrying out research into the molecular basis of virulence in *Salmonella* pathogens. Research emphasis will be on determining the distribution and precise function in various *Salmonella* serotypes of a plasmid DNA sequence that appears to play a major role in virulence. Ref: 565.

Applicants should have a first or upper second class honours degree and PhD. Experience of immunology would be an added advantage.

(2) IMMUNOLOGIST OR VIROLOGIST

Required to join a project investigating the potential of monoclonal antibodies as prophylactic and therapeutic agents against respiratory syncytial virus infection. Experience in production and characterisation of monoclonal antibodies would be an advantage. Ref: 566.

Students completing PhDs in Autumn 1985 will also be considered.

For further information contact David Baird (ref 565) or Jim Stott (ref 566) on 0635 22 411.

Appointments will be to Higher Scientific Officer grade, salary scale £7,435 — £10,039 (under review) depending on qualifications and experience. Non-contributory pension scheme.

The Institute is set in pleasant rural surroundings with canteen and recreational facilities.

The AFRC is an equal opportunities employer.

Application forms from: Secretary, IRAD, Compton, Newbury. RG16 ONN, quoting appropriate ref. (6562)A

KINGSTON POLYTECHNIC
Faculty of Science
School of Applied Physics
CEGB LECTURESHIP IN APPLIED PHYSICS

Applicants should have worked in an area of physics applications, eg in applied optics, environmental measurement, development of instrumentation, which would be of interest to CEGB research.

The person appointed will be required to contribute to the teaching of the School of Applied Physics up to degree level. He or she will also be a recognized member of the appropriate research team at the CEGB Research Laboratories, Leatherhead, with access to a comprehensive range of equipment and instrumentation, and will be expected to carry out research both at CEGB and at the Polytechnic.

Salary range LII/SL £8,226 — £14,739 including London allowance.

Details and application forms (quoting ref PHB2) from Personnel Officer, Kingston Polytechnic, Penrhyn Road, Kingston Upon Thames KT1 2EE. Tel 01-549 1366 ext 287.

Re-advertisement — previous applicants need not re-apply. Closing date 1/7/85. (6547)A

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
(University of London)
DEPARTMENT OF BIOCHEMISTRY AND CHEMISTRY
LECTURESHIP

Applications are invited for a newly-created Wellcome Trust Lectureship for 5 years (subject to review after three years).

Applicants should have specific interest in research on membrane-bound receptors. The successful applicant will be expected to develop his or her own research programme and also to collaborate in related research in the Department, and to participate in the teaching programme.

Applicants shall not be more then 35 years old, nor holders of a tenured post. Salary on the scale £7,520 — £14,925 plus £1,233 London Allowance.

Further particulars may be obtained from the School Office RFHSM, Rowland Hill Street, London, NW3 2PF (01-794-0500 ext 4262) to which applications, including a curriculum vitae, the names of three referees and a 500 word summary of the research proposed should be submitted by 14 June. Please quote reference JAL/WL/2. (6552)A

The Department of Pediatrics at the University of California, San Diego is seeking a candidate for a 75% to 80% time faculty position at the Assistant Clinical Professor level in the Division of Adolescent Medicine. Position will have the responsibility of attending in community Adolescent Medicine Clinics, and work on inpatient and outpatient, and teaching residents. Candidate must be able to obtain California license and be board eligible or certified in Pediatrics. Experience or fellowship training in Adolescent Medicine is desirable. Salary will be commensurate with experience and U.C.S.D. policy.

Interested persons should forward curriculum vitae and the names of three references by June 1, 1985 to: Marianne Felice, M.D., Director, Adolescent Medicine, Department of Pediatrics, UCSD Medical Center, Box 3548, San Diego, California 92103. *The University of California, San Diego is an Equal Opportunity/Affirmative Action Employer* (NW1770)A

IMPERIAL COLLEGE
(University of London)
Physiological Flow Studies Unit
POST-DOCTORAL RESEARCH ASSISTANT
FLOW IN DEFORMABLE POROUS MATERIALS

Support is available for a post-doctoral research assistant to undertake studies of flow in deformable porous materials. The work, which has wide relevance, will involve experimental studies and numerical analysis. The research is supported by the BP Research Centre, Sunbury (with whom close contact will be maintained) but will be carried out at the Physiological Flow Studies Unit, Imperial College. The appointment is for one year but the possibility exists of extension for a further year.

Applications (including curriculum vitae and names of two referees) should be submitted not later than 27th June, 1985 to Prof. C.G. Caro, Physiological Flow Studies Unit, Imperial College, London SW7 2AZ. For further information, apply to Prof. Caro (589 5111 ext. 4082) or Dr K H Parker (589 5111 ext. 4085). (6521)A

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL
London W1P 6DB
(University of London)
THE COURTAULD INSTITUTE OF BIOCHEMISTRY, AND THE DEPARTMENT OF ANATOMY AND BIOLOGY AS APPLIED TO MEDICINE
RESEARCH ASSISTANT

Applications are invited for the post of Research Assistant to work on the molecular basis of limb development in the chick embryo, for two years from 1 September. The work is supported by the Nuffield Foundation. Previous experience in cDNA cloning technology is not essential but would be an advantage. Applications are welcomed from those with postgraduate experience as well as new graduates.

Applications, together with the names of two referees, should be sent to either Professor R K Craig at The Courtauld Institute, or Professor L Wolpert, Department of Anatomy and Biology as Applied to Medicine. (6535)A

UNIVERSITY OF DUNDEE
DEPARTMENT OF BIOCHEMICAL MEDICINE
Applications are invited for a post as
LECTURER IN APPLIED BIOCHEMISTRY

in the above Department based in Ninewells Hospital and Medical School. Candidates should have a good honours degree in Biochemistry or Chemistry, and a higher degree with postgraduate experience in either immobilisation of enzymes, microbiological degradation of biochemicals or related topics. The Appointee will be expected to undertake research and contribute in particular to an established MSc Course in Analytical Biochemistry.

The appointment will be made on the Lecturer scale (currently £7,520 — £14,925, but due for review) with point of entry dependent on qualifications and experience.

Further Particulars are available from The Personnel Officer, The University, Dundee DD1 4HN, with whom applications (6 copies containing full career details and the names of three referees) shold be lodged by 29th June 1985. Please quote reference EST/16/856(J). (6518)A

UNIVERSITY OF NEWCASTLE UPON TYNE
DEPARTMENT OF OCCUPATIONAL HEALTH & HYGIENE
CHAIR OF OCCUPATIONAL HEALTH AND HYGIENE

Applications are invited for the Chair of Occupational Health & Hygiene which will fall vacant on 1 October 1985, on the retirement of Professor R I McCallum. Candidates should be registered medical practitioners and hold a higher medical qualification. The successful candidate will be accorded Honorary Consultant status by the Newcastle Health Authority and will be appointed to the headship of the University Department of Occupational Health & Hygiene for an initial period of five years.

Applications (15 copies), giving the names of not more than three referees must be lodged with the Senior Assistant Registrar, The Medical School, Framlington Place, Newcastle upon Tyne NE2 4HH, not later than 14 June 1985, from whom further particulars can be obtained. (Applicants from outside the British Isles may submit one copy only) (6553)A

ANIMAL VIRUS RESEARCH INSTITUTE

HIGHER SCIENTIFIC OFFICER BAND 1

Structure and function of the Bluetongue virus genome.

Applications are invited for the above post which will be concerned with genetic analysis, cloning and sequencing of bluetongue virus genomes.

This is a new position within the Division of Molecular Biology, which is one of three Divisions within the Institute and comprises some 20 -25 scientific staff.

The appointee would work closely with Dr P Mertens in the Biochemistry Department, who has already established the coding assignments of bluetongue virus type 1 (See Virology 135, 207-217 1984), which is a highly virulent strain causing disease in sheep. Clones of the virus genome will be obtained both for sequencing studies and also for use as diagnostic probes for the detection of bluetongue virus RNA segments. The position would suit someone with a strong background in molecular biology. Previous experience with viruses is not essential. (6494)A

KINGSTON POLYTECHNIC

School of Applied Physics

RESEARCH ASSISTANT IN FIBRE OPTICS

Required to investigate the Interaction of optical signals with lattice vibrations (Brillouin scattering) in optical fibres. The work is directed towards the development of fibre-optic sensors and is a collaborative project between the School and the CEGB Research Laboratories, Leatherhead.

The Assistant will be based at Kingston but will work in association with a research group at Leatherhead and have access to facilities there.

Candidates should have a good Honours degree or should be expecting to graduate shortly in Physics or a related science and will be expected to register for MPhil/PhD with CNAA

Salary range £5,859 — £6,588 including London allowance.

Details and application forms (quoting ref PHB1) from Personnel Officer, Kingston Polytechnic, Penrhyn Road, Kingston Upon Thames KT1 2EE Tel 01-549 1366 ext 287 (6548)A

ICARDA

International Center for Agricultural Research in the Dry Areas

HEAD COMMUNICATIONS AND DOCUMENTATION

The International Center for Agricultural Research in the Dry Areas (ICARDA) invites applications for the position of Head Communications and Documentation to be based at the Headquarters in Aleppo, Syria.

RESPONSIBILITIES:

Direct the Department of Communications and Documentation which is primarily responsible for gathering, producing, and disseminating information on the Center's research and training activities. Involves writing and editing, production of internal and external newsletters and other publications, graphic arts, audio visual presentations, printing and computerized storage and retrieval of scientific information.

QUALIFICATIONS:

Bachelor of Science or advanced degree in agricultural journalism or closely related field, at least 10 years in responsible position in agricultural information/communication work; some international experience preferred; demonstrated competence in supervision of a staff and management of overall agricultural information operations. Knowledge of French desirable.

CONDITIONS OF APPOINTMENT;

International tax-free salary based on background and experience; use of car; allowance towards housing; annual home leave; non-contributory medical insurance scheme and pension fund.

Candidates should submit two copies of their Curriculum Vitae and samples of work, plus names of two referees quoting REF. COMM/1/85. to:

Dr. Mohammed A. Nour,
Director General,
ICARDA, P.O. Box 5466,
Aleppo, Syria.

(W1877)A

UNIVERSITY OF LEEDS

DEPARTMENT OF CHEMICAL PATHOLOGY
(In collaboration with Department of Genetics)

POSTDOCTORAL RESEARCH FELLOW

Applications are invited for the above post to work on the DNA sequence diversity of the Y-chromosome of the mouse The appointment will be made from 1 October 1985 for a fixed period of up to two years

Candidates with experience of recombinant DNA techniques would be preferred but previous work with mammals is not a requirement.

Salary on the IA Range for Research and Analogous Staff (£7,520 — £12,150)(under review) according to age, qualifications and experience

Informal enquiries to Dr A D Steward (0532 432799 ext 3927) or Professor D J Cove (Genetics — 0532 431751 ext 599) are invited

Application forms and further particulars may be obtained from The Registrar, The University, Leeds LS2 9JT quoting reference number 84/16 Closing date for applications 13 June 1985 (6564)A

THE UNIVERSITY OF LANCASTER

LOW TEMPERATURE PHYSICS

A postdoctoral Research Associate is needed to participate in an SERC-funded research programme on the breakdown of superfluidity in liquid ^{4}He at mK temperatures The post is tenable from 1 July (or as soon as possible thereafter) for up to three years. Salary within the first two points of Research 1A scale (£7,520 — £7,980 under review) Informal enquiries may be made to Dr P V E McClintock, tel no 0524 65201 ext 4178.

For further particulars and application form, please write to the Establishment Office (quoting reference L208/C), University House, Bailrigg, Lancaster LA1 4YW, where applications (six copies) naming three referees should be sent to arrive NOT LATER THAN 21 JUNE 1985. (6602)A

AN ACTIVE FERTILITY AND IN VITRO PROGRAMME IS DUE TO OPEN AT THIS HOSPITAL ON 1st AUGUST 1985

Applications are invited for the following position, for which date of commencement will be by mutual agreement

TECHNICAL ASSISTANT/EMBRYOLOGIST

The successful applicant will be expected to undertake both routine laboratory and research work Research is currently undertaken in collaboration with MRC (Carshalton) and the Institute of Animal Physiology (Cambridge)

Experience in mammalian embryology would be desirable and a PhD or MSc in reproductive physiology or embryology would be an advantage, but is not essential

The Hospital offers a generous salary and excellent benefit package.

Applicants should forward a Curriculum vitae, including the names of three referees to: The Personnel Department, Humana Hospital Wellington, Wellington Place, London NW8

Closing Date 22nd June 1985 (6599)A

Humana Hospital Wellington

Wellington Place London NW8 9LE

ASSISTANTSHIPS

KINGSTON POLYTECHNIC
Faculty of Science
RESEARCH ASSISTANTSHIPS

Applications are invited for the following Research Assistantships:-

Post 1 (Ref GP2)

SYNTHESIS OF NOVEL CROSSLINKED POLYMERS

This post is with an established group developing new kinds of thermosetting polymers and studying the relationship between their structure and properties.

Post 2 (Ref GAS 1)

MECHANISTIC INVESTIGATION OF THE FLAME RETARDANT AND SMOKE SUPRESSANT ACTIVITY OF SPECIFIC POLYMER ADDITIVES

This study involves polymer synthesis and analysis of an assessment of flammability. Techniques include thermogravimetry, IR and NMR spectroscopy, capillary GC/MS.

Posts 1 and 2 are the result of Kingston Polytechnic being identified as a centre to receive special research funding in science and engineering from the National Advisory Body.

Post 3 (Ref RD1)

INORGANIC AND PHYSICAL CHEMISTRY

This post involves the study of paramagnetic vanadium compounds with organic molecules and is directed towards the development of new organic reactions in the presence of transition metal catalysts.

Post 4 (Ref CHJW 1)

PHOTOCHEMISTRY OF PESTICIDES

This post is to work on research into the effect of light on pesticides The research relates to the fate of pesticides and related materials when exposed to sunlight in the environment, and will provide the opportunity to gain experience of a variety of radiochemical techniques and of modern spectroscopic methods of structure determination

Applicants should hold or expect to gain an Honours degree or equivalent qualification.

Research Assistantships are normally made for a period of 3 years Salary scale £5,859 — £6,588 including London Allowance

SERC STUDENTSHIPS

Applications are invited for the following SERC studentships:

Post 5 (Ref QC 1)

CHEMISTRY RESEARCH

The research interests of the department include aspects of organic, organometallic, inorganic and polymer chemistry, as well as photochemistry and analytical chemistry

Post 6 (Ref RD 2)

INORGANIC AND PHYSICAL CHEMISTRY

This post is to study the reactivity of metal co-ordinated carbonyl ligands with anionic nucleophiles in the presence of group 1 metal-crown ether complex cations and is directed towards the catalysed synthesis of oxalate esters

Applicants for these posts should hold or expect to gain at least an upper second class Honours degree or equivalent qualification SERC studentships are normally for a period of 3 years and candidates will be expected to register for a higher degree.

Application forms and further details for all the above posts are available from the Staffing Officer, Kingston Polytechnic, Penrhyn Road, Kingston Upon Thames KT1 2EE. Tel. 01-549 1366 ext 287. Please quote reference no. when requesting details. (6549)P

POSTDOCTORAL RESEARCH ASSISTANTSHIPS

Applications are invited from chemists who have experience in the synthesis of natural products and in the field of enzymology.

The appointment is on the RA1A scale and would be for one year from September 1985, with starting salary up to £8,920 pa according to age and experience plus USS.

Applicants with the names and addresses of two referees should be sent to Professor J E Baldwin, The Dyson Perrins Laboratory, South Parks Road, Oxford OX1 3QY as soon as possible (6542)P

UNIVERSITY OF BRISTOL
DEPARTMENT OF BIOCHEMISTRY AND UNIT OF MOLECULAR GENETICS

POST DOCTORAL/ POST GRADUATE RESEARCH ASSISTANT

Applications are invited for a SERC funded Research Assistantship to join a research group actively working on the molecular genetics on Drosophila melanogaster. The work will involve the characterisation of a gene which controls pigmentation of the cuticle using spontaneous and hybrid dysgenesis induced mutants. DNA cloning, sequencing and in situ hybridisation methods will be employed

The laboratory is well funded and this position is supported for 3 years. Starting salary up to £7,980 p.a (Range 1A) Candidates with a PhD and experience in nucleic acids and/or genetics are preferred; however graduates with a good honours degree and pertinent research experience will be considered at the RA1B level. This position can be taken up immediately

Curriculum vitae along with the names and telephone numbers of three referees should be sent to Dr William Chia, Department of Biochemistry, University of Bristol, Bristol BS8 1TH. Tel 0272 24161 ext 1190 as soon as possible. (6567)P

FELLOWSHIPS

MONASH UNIVERSITY
Melbourne, Australia

POST-DOCTORAL FELLOWSHIPS

Monash University is offering a number of Post-Doctoral Fellowship positions commencing in 1986 and tenable for up to two years in any department of the University. Fellows will be expected to collaborate in their research with a member of the University staff. intending applicants should contact the Chairman of the Department in which they wish to work to discuss possible areas of mutual research interest.

Appointments will be in the Research Fellow I range ($A22,614 — $A25,246), but an appointment at Research Fellow Grade II level ($A26,236 — $A34,467) may be considered in exceptional circumstances. Reference No 90162

Applications will only be accepted on the official Application Form. This and other details available from the Registrar, Mr J D Butchart, Monash University, Clayton, Victoria 3168, Australia Applications close 30 August 1985.

An Equal Opportunity Employer. (W1884)E

THE UNIVERSITY OF SHEFFIELD
FACULTY OF MEDICINE

J G GRAVES MEDICAL RESEARCH FELLOWSHIP

Applications are invited for the above Fellowship tenable for a period of three years from 1 October 1985. The Fellow will be required to undertake full-time medical research in one of the medical or dental departments or hospital. Initial salary according to qualifications and experience within the range £7,520 - £8,920 a year. Additional funds may be available for the Provision of laboratory assistance and materials.

Further particulars from the Personnel Department (Academic Staffing), the University, Sheffield S10 2TN to whom applications (10 copies), including the names and addresses of three referees, (indicating the line of research proposed), should be made by 17 June 1985. Quote ref: R269/G. (6588)E

Melbourne, Australia

LA TROBE RESEARCH FELLOWSHIPS 1985/86

Applications for Research Fellowships are invited from persons who have gained doctoral or equivalent qualifications within the last five years A project must be proposed by an applicant and should ideally be in collaboration with a La Trobe University research worker or team of the applicant's choice, that is, it should complement an existing area of research at La Trobe.

Fellowships will be awarded for an initial period of 12 months with the possibility of renewal for a further maximum period of 12 months.

Salary offered is within the range of $A22,614 — $A26,236

A Fellowship will not be awarded to an applicant who holds a permanent appointment

Prospective applicants should note that application must be made on the University's form which will be sent on request together with a copy of the Conditions of Award.

Enquirers should briefly indicate the research discipline of interest to them The closing date for applications is 30 September 1985 For further information, write to the Staff Officer, La Trobe University, Bundoora, Victoria 3083, Australia (W1883)E

FELLOWSHIPS continued

EMBO
EUROPEAN MOLECULAR BIOLOGY ORGANIZATION
SHORT TERM FELLOWSHIPS
in molecular biology

The European Molecular Biology Organisation awards, to scientists working in Europe and Israel in the field of molecular biology and allied disciplines, short term fellowships of one week up to three months duration. The fellowships are to support collaborative research between laboratories in different countries and provide a travel grant and subsistence allowance. Applications may be made at any time and are decided upon soon after the receipt of application

Applications for exchanges between laboratories within any one country cannot be considered. Fellowships involving transatlantic travel are awarded only in extremely exceptional circumstances.

Application forms and further details may be obtained from Dr J. Tooze, Executive Secretary, European Molecular Biology Organization, 69 Heidelberg 1, Postfach 102240, F.R.G. (W1577)E

UNIVERSITY OF YORK
DEPARTMENT OF CHEMISTRY
POSTDOCTORAL RESEARCH FELLOWSHIP

Applications are invited for a Postdoctoral Fellowship for work, in association with Professor R E Hester, on the spectroscopic determination of secondary structure in proteins. Laser Raman spectroscopy will be the principal techniques used in this work, a part of which will take place at the SERC central laser facility in the Rutherford Laboratory, near Oxford. Applicants should have experience in protein biochemistry and/or vibrational spectroscopy.

The post is available immediately for a period of two years. Salary within the IA range — £7,520 to £12,150 pa, with USS.

Two copies of applications, with full curriculum vitae and naming two referees, should be sent as soon as possible to Professor R E Hester, Department of Chemistry, University of York, Heslington, York YO1 5DD. Please quote reference number 11/6206. (6591)E

LUDWIG INSTITUTE FOR CANCER RESEARCH
(Cambridge Branch)
POST-DOCTORAL FELLOW

Applications are invited for a post-doctoral fellowship in the laboratory of Dr A R MacLeod to work on the molecular biology of human cytoskeletal tropomysins. The Cambridge branch of the Ludwig Institute is situated adjacent to the Laboratory of Molecular Biology and offers the opportunity to join a young group working in a stimulating academic environment. The position is tenable from 1 January 1986 or as soon as possible thereafter for a period of two years with the possibility of a year's renewal. Salary is commensurate with experience on the Grade II (non-clinical) scale (£11,205 max).

Applications including a CV and names and addresses of two referees should be sent to The Administrator, Ludwig Institute for Cancer Research, MRC Centre, Hills Road, Cambridge CB2 2QH, England. (6473)E

STUDENTSHIPS

UNIVERSITY OF GLASGOW
BIOTECHNOLOGY UNIT
SERC CASE STUDENTSHIP — ICI

To clone and study expression of resistance and production genes from Streptomyces for an antibiotic of interest to ICI. The project is supervised jointly by Dr I S Hunter (Glasgow) and Dr P Groves (ICI, Corporate Lab, Runcorn).

Applicants should have, or expect to obtain, a first or upper second class honours degree in a related biological science. Interviews will be conducted towards the end of June.

Applications (CV and names of two referees) should be sent to Dr I S Hunter, Institute of Genetics, Church Street, Glasgow G11 5JS, before June 13th, 1985. (6596)P

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE
Wolfson Unit
PhD STUDENTSHIPS

Available immediately for research on the molecular biology/immunology of the viral agents of hepatitis and dengue.

For further details send full curriculum vitae, naming three professional referees, to the Registrar, London School of Hygiene and Tropical Medicine, Keppel Street, London WC1E 7HT (6539)F

LONDON SCHOOL OF HYGIENE & TROPICAL MEDICINE
(UNIVERSITY OF LONDON)
KEPPEL STREET, LONDON, WC1E 7HT

MRC Studentship

Applications are invited for a three year MRC Research Studentship tenable from October 1985. The project will be concerned with comparative studies on the immunology of *Schistosoma mansoni* and *S. japonicum* with emphasis on the identification of the "protective" antigens and cloning of the corresponding antigen genes.

This work will be carried out in part at Winches Farm Field Station, but mainly in the School's Wolfson Unit for Molecular Medical Microbiology and Parasitology in London.

Applicants, who must hold, or hope to obtain in June 1985, a first or upper second class honours degree in Molecular Biology, Microbiology or Biochemistry, will be registered for a PhD degree.

Applications consisting of full C.V. and naming two referees should be sent to Dr Q.D. Bickle, London School of Hygiene and Tropical Medicine, Winches Farm Field Station, 395 Hatfield Road, St. Albans, Herts AL4 0XQ. (6605)F

Brighton Polytechnic

DEPARTMENT OF PHARMACY
Applications are invited for the following SERC CASE Awards:

1 Difussion of antibiotic molecules through biopolymer gels, in conjunction with Beecham Pharmaceuticals Research Division;
2 Evaluation of the ciliotoxicity of pharmaceuticals, in conjunction with the Wellcome Foundation.

Applicants should possess a good honours degree in Pharmacy, Physiology, Biochemistry or a related discipline. Normal SERC conditions apply and candidates will be expected to register for a higher degree.

Further information and forms of application may be obtained from Personnel Department, Brighton Polytechnic, Mithras House, Telephone: Brighton 693655 Ext. 2536. Closing date 4 June 1985. (6612)F

QUEEN MARY COLLEGE
(University of London)
SCHOOL OF BIOLOGICAL SCIENCES
SERC CASE STUDENTSHIPS

Applications are invited for SERC-CASE Studentships in the following areas.

1. Microbial Ecophysiology/Biochemisty (Dr J P Robinson)

Investigation of the anaerobic decomposition of chlorinated hydrocarbons by bacteria in land-fill will be carried out in collaboration with Dr R Sleat, BioTechnica Ltd, Cardiff. The work will involve characterisation of anaerobic decomposition processes using a wide variety of microbiological and analytical techniques including GLC and HPLC

2. Plant Biochemisty (Dr P Heathcote)

The isolation, purification and characterisation of acetyl-CoA carboxylase from spinach leaf chloroplasts will be undertaken in collaboration with Dr A P Slabas, Unilever Research. The possible regulation of leaf and seed lipid synthesis by different forms of enzyme will be investigated

Applications including a current curriculum vitae and the names of two referees should be sent as soon as possible to Dr J P Robinson or Dr P Heathcote, School of Biological Sciences, Queen Mary College, Mile End Road, London E1 4NS. Applicants should have or expect to have a first or upper second class honours degree in a relevant subject area (6574)F

Continued on page 22

UNIVERSITY OF KENT
AT CANTERBURY

BIOLOGICAL LABORATORY

Applications are invited for the following two SERC CASE studentships under the supervision of Dr R B Cain.

(i) in collaboration with Castrol Research Laboratories, Pangbourne, to investigate the metabolic fate in soil and activated sludge of synthetic two-stroke motor lubricants with particular reference to the enzymes involved in degrading branched chain hydrocarbon residues.

(ii) in collaboration with the Glasshouse Crops Research Institute, Littlehampton, to examine the physiology, biochemistry and enzymology of lignin and lignocellulose degredation by edible fungi, including the common mushroom *Agaricus*

These projects both complement existing research programmes with research grant support. Applicants should either hold, or expect to obtain in 1985, at least an upper second-class Honours degree in an appropriate subject area Applications with the names of two referees, or with references enclosed, should be directed without delay to the Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory. University of Kent, CANTERBURY, CT2 7NH from whom further details are available Please quote ref· PG12/85 (6561)F

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF ORGANIC CHEMISTRY

SERC CASE AWARD

Applications are invited for an SERC CASE studentship (Cambridge Research Biochemicals collaborating company), to work on a project entitled "New Methods for the Conjugation of Peptides".

The successful applicant will carry out studies leading to the degree of PhD under the supervision of Dr I J Galpin. The work will involve solid phase peptide synthesis and conjugation of synthetic peptides to protein carriers in order to facilitate antibody generation.

Although biological aspects of the programme will be carried elsewhere, the applicant will acquire a good knowledge of the synthesis and manipulation of peptides and proteins and will join a group working on various aspects of peptide chemistry

Applicants should possess or expect to receive a First or Upper Second Class Honours Degree in Organic Chemistry, although Honours Graduates from other disciplines, such as biochemistry maybe considered providing they have sufficient background and knowledge of organic chemistry.

Applications, together with the names of two referees should be received as soon as possible by The Registrar, The University, PO Box 147, Liverpool L69 3BX. Quote ref RV/283 (6559)F

UNIVERSITY OF LONDON

Institute of Psychiatry

DEPARTMENT OF PSYCHOLOGY

SERC RESEARCH STUDENTSHIP

Applications are invited for a research studentship, leading to a PhD D,tenable for 3 years from October 1985. Applicants should hold or expect to receive a first or upper second class Honours degree and have a background in psychology or a branch of neurobiology. The successful candidate will join a research group that aims to apply the techniques of contemporary neurobiology to the study of the control of behaviour by the brain. The group collaborates closely with the Departments of Biochemistry and Neuropathology and training is available in a range of appropriate techniques.

Applicants should write to Professor J A Gray, Department of Psychology, Institute of Psychiatry, De Crespingy Park, Denmark Hill, London SE5 8AF, giving details of their curriculum vitae, the names of two referees and an indication of their preferred field(s) of research. Closing date for applications: 7 June 1985 (6520)F

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF BIOCHEMISTRY

SERC CASE STUDENTSHIP

Applications are invited for a studentship leading to the degree of PhD on "Controlled proteolysis of the sweet protein — thaumatin" The collaborating body of Tate and Lyle, plc and the industrial supervisor is Dr P B Rodgers Candidates should possess or expect to receive a 1st or upper 2nd class degree in Biochemistry or a related subject.

Applications, together with the names of two referees should be received as soon as possible by The Registrar, The University, PO Box 147, Liverpool L69 3BX Quote Ref: RV/279 (6538)F

UNIVERSITY OF SOUTHAMPTON

Faculty of Medicine

RESEARCH STUDENTSHIP

Applications are invited for a University Research Studentship for 3 years in the Clinical Pharmacology Group The student should have (or expect to obtain) a First or Upper Second Class Honours Degree in Pharmacology, Biochemistry or related Biological Sciences and will register for a PhD. The project will investigate the processes involved in hormone production (including prostaglandins and leukotrienes) in gastrointestinal disease. Further information can be obtained from Dr K Hillier, 0703 559122 Ext 4264. The grant will be at the appropriate MRC scale rate.

Applications giving full cv and the names and addresses of two referees should be sent as soon as possible to Dr K Hillier, Clinical Pharmacology Group, University of Southampton Bassett Crescent East, Southampton, SO9 3TU. Please quote ref no AJS/85/32. (6525)F

THE UNIVERSITY OF SHEFFIELD

Amorphous and Crystalline Quantum Well Semiconductors

DEPARTMENT OF PHYSICS

SERC PhD STUDENTSHIP

Applications are invited from graduates with a class I or II 1 Honours degree in Physics, Materials Science or Electronic Engineering, for an SERC Information Technology award, to study luminescence in extremely thin layer structures of amorphous silicon which show quantum size effects Comparative studies on GaAs superlattices will be included. The successful candidate will join an established group in the field of amorphous semiconductors especially interested in the study of photo-and electro-luminescence, using lasers and related opto-electronic techniques. We are chiefly interested in recombination mechanisms and photo induced defects This work is being extended to include quantum size effects in both amorphous silicon and crystalline III-V semiconductors. The group collaborates actively with a number of workers in the device field The project will involve a wide range of solid state techniques with emphasis on the physics of these materials. Tenable from 1 October 1985.

Applications with the names of two referees should be sent to Professor I G Austin, Department of Physics, The University, Sheffield S10 2TN by 6 June 1985. Quote ref: R268/G. (6585)F

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF MEDICAL CELL BIOLOGY

PhD STUDENTSHIP ON THE MOLECULAR MECHANISMS OF CELL MOTILITY

A University of Liverpool postgraduate studentship (same conditions as MRC studentship) is available from October 1985 to work in a group studying the molecular mechanisms of non-muscle cell motility. Interests of the group include the cellular regulation of actin filament assembly and the mechanisms by which the spatial organisation, polarity and anchorage of filaments is determined during cell motility.

The project will involve the development of experimental approaches to the study of possible myosin-independent movement resulting from the polymerisation of actin filament bundles and the Donnan-induced shape changes in cross-linked actin filament networks. Studies with purified proteins will be correlated as far as possible with the cellular behaviour of actin filament networks in cells. Informal enquiries may be made to Dr P Sheterline, Tel 051-709 6022 ext 2842.

Applications, together with the names of two referees, should be received as soon as possible by The Registrar, The University, PO Box 147, Liverpool L69 3BX.

Quote Ref: RV/288/N. (6586)F

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF BIOCHEMISTRY

SERC CASE STUDENTSHIP IN PROTEIN MODIFICATION AND DESIGN

Applications are invited for a three-year Postgraduate Case Studentship with G D Searle and Co Ltd, leading to the degree of PhD at the University of Nottingham, from Students who have or expect to obtain a First or Upper Second Class Honours Degree in Molecular Biology, Biochemistry or a related biological subject.

The proposed Project is directed towards an investigation of two animo transferase enzymes and will offer training in a range of biochemical, molecular biological and genetic techniques. In particular it will involve oligonucleotide directed mutagenesis, recombinant and DNA technology protein purification, enzymology and computer modelling.

The research will be supervised by Dr R E Glass in collaboration with Dr M G Hunter of G D Searle and Co Ltd. The student will be expected to spend part of the time in G D Searle's Laboratories at High Wycombe

Applications, including two copies of a curriculum vitae and the names of two referees should be sent by 14th June 1985 to Dr R E Glass, Department of Biochemistry, University of Nottingham, Queens Medical Centre, Nottingham, Notts, NG7 2UH. Tel 0602 700111 ext 3395

Informal enquiries should be directed to Dr M G Hunter. Tel 0494 21124 ext 3401. (6569)F

JOHN INNES INSTITUTE

GRADUATE STUDENTSHIPS IN PLANT VIROLOGY

Three studentships are offered for prospective PhD students in the Department of Virus Research of the John Innes Institute. The research topics are (i) Strain differentiation in Beet Yellow Virus (Dr R Hull), (ii) Molecular biology of a tobravirus (Dr J W Davies in collaboration with Dr K R Wood in Birmingham University), (iii) Changes in host gene expression in virus-infected plant tissue (Dr A S Maule).

The John Innes Institute is affiliated with the nearby University of East Anglia and graduate students working here are entitled to use all the academic and social facilities of the University as well as the excellent facilities of the Institute.

Prospective applicants should write to the project supervisor for further details. The financial arrangements for the studentships will be the same as those of the usual Research Council Studentships Applications, with full cv, should be sent to the Secretary, John Innes Institute, Colney Lane, Norwich NR4 7UH. (6543)F

UNIVERSITY OF DURHAM

DEPARTMENT OF ZOOLOGY

RESEARCH STUDENTSHIP

Applications are invited from candidates, preferably with an interest in Cell Biology, who hold or expect to be awarded at least 2:1 honours in Biology or Biochemistry for a North of England Cancer Research Campaign Studentship to study the relationship between the thermal sensitivity of tumour cells and the biochemistry of the tumour cell membrane. The award is for 3 years from October 1985 and the successful candidate must register for a higher degree.

Applications (curriculum vitae and 2 academic referees) should be sent by 31 May 1985 to Professor K Bowler, Department of Zoology, Science Laboratories, South Road, Durham, DH1 3LE. (6528)F

THE UNIVERSITY OF NEWCASTLE UPON TYNE

DEPARTMENT OF ZOOLOGY

RESEARCH STUDENT IN NEUROBIOLOGY

Applications are invited for a research studentship, which has been awarded by SERC for research in Invertebrate Neurobiology. Research interests are in the physiology of synaptic transmission between visual neurones in insects, and in the roles which identified neurons play in the control of behaviour. The studentship is tenable for three years from October 1985. Candidates are required to obtain a 1st Class or Upper Second Class Honours Degree in Zoology or Physiology.

Applications, with the names of 2 academic referees, or requests for information to be sent as soon as possible to: Dr P J Simmons, Department of Zoology, The University, Newcastle Upon Tyne NE1 7RU. (6532)F

UNIVERSITY OF BRADFORD

SERC/CASE RESEARCH STUDENTSHIP IN CHEMISTRY

Applications are invited for the above studentship in collaboration with UKAEA, Windscale, from 1 October, 1985 leading to a PhD. The project involves the application of Raman microscopy to chemical problems associated with nuclear reactors and the feasibility of using remote control Raman microscopy for the in-situ study of radioactive materials. Applicants must hold or expect to gain a first or upper second class Honours Degree in Chemistry or its equivalent.

Applications, including the names and addresses of two academic referees and a CV should be sent to: Professor D A Long/Dr H G M Edwards, Molecular Spectroscopy Unit, School of Chemistry, University of Bradford, W Yorks BD7 1DP. (6583)F

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF PLANT BIOLOGY

OPPORTUNITIES FOR POSTGRADUATE STUDY COMMENCING OCTOBER 1985

Studentships are available for PhD study in the following research areas or projects.

1) NERC (CASE) with Dr B Leadbeater, on the turnover of organic matter in the sea by heterotrophic chrysomonads (in collaboration with Marine Biological Association).

2) SERC (CASE) with Dr M T Jackson and Prof J A Callow, on the physiology and genetics of the non-blackening character of wild potatoes.

3) SERC (CASE) with Dr B Leadbeater and Dr T R Bott (Dept of Chemical Engineering), on the use of ozone as a biocide in water systems (in collaboraton with Ozotech Ltd).

4) SERC (CASE) with Dr B Leadbeater, on the physiology of movement and structure of the haptonema in coccolithophorid algae (in collaboration with Marine Biological Association).

5) Department Studentship in Plant Genetic Resources, to work on one of the following aspects of plant genetic resources; isoenzymes and genetic diversity of potato, regulation of metabolic activity in recalcitrant seeds, anther culture in breeding of Alliums, promotion of germination in hard seeds in relation to genebank activities. Applications in this case should be addressed to Prof J A Callow.

Applicants should possess a first or upper second class honours degree in an appropriate biological subject. Applications (2 copies including cv) should be addressed directly to the Supervisors indicated and further details may be obtained from them at the following address. Dept of Plant Biology, University of Birmingham, PO Box 363, Birmingham B15 2TT. (6544)F

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF BIOCHEMISTRY

SERC STUDENTSHIP

October 1985

Applications are invited for a studentship expected to lead to a PhD degree for research on inherited biochemical lesions resulting in ketoacidosis in humans. The work will involve cultured skin fibroblasts from affected and unaffected individuals. Applicants will need a first or upper second class honours degree in Biochemistry or a closely related subject.

Applications including curriculum vitae and names of two academic referees to Dr B Middleton, Department of Biochemistry, University of Nottingham Medical School, Queen's Medical Centre, Nottingham NG7 2UH. (6530)F

UNIVERSITY OF KENT AT CANTERBURY

Biological Laboratory

The following research studentships for postgraduate research are available in the Biological Laboratory Applicants must have, or hope to obtain, an upper second or first class honours degree

SERC Quota Studentships*

1 Molecular Biology of Microtubules Differential Expression of a Tubulin Multi-Gene Family DR K GULL
2 The Bioenergetics of Methanogenic Bacteria DR I SALMON
3 Regulation of Bacterial Secondary Metabolite Production DR A W BUNCH.

SERC CASE Studentships*

4. Disulphide Bonds and Conformation of Recombinant Proteins DR R B FREEDMAN with DR J E FITTON, ICI Pharmaceuticals, Alderly Edge
5 Differential Gene Expression in a Eukaryotic Microbe DR K GULL with DR R COX, MRC Laboratory, Mill Hill

SERC Biotechnology Directorate Studentships

6 Physiology of Immobilised Steroid-Transforming Fungi PROFESSOR A T BULL
7 Catalysis by Redox Enzymes in Water/Oil Microemulsions. DR R B FREEDMAN and DR B H ROBINSON

NERC Studentships

8 Use of Monoclonal Antibodies for Distinguishing Hyphae of Root Infecting Fungi DR P JEFFRIES and DR K GULL

Applicants should indicate the projects for which they wish to be considered and should submit a curriculm vitae together with the names of two referees to the Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory, The University, Canterbury, Kent CT2 7NH from whom further details are available on request Please quote ref PG11/85 (6554)A

SOUTH MANCHESTER HEALTH AUTHORITY

Christie Hospital & Holt Radium Institute

PATERSON LABORATORIES

DEPARTMENT OF BIOCHEMICAL GENETICS

SERC/CASE RESEARCH STUDENTSHIP

Applications are invited from candidates with, or expecting to gain, a good honours degree in Biological Sciences for this 3 year project leading to a PhD degree The project is concerned with the study of gene expression in differentiation and will involve the use of viral vectors to introduce cloned genes into recipient cells and is in collaboration with ICI Pharmaceuticals Division, Alderley Edge, Cheshire.

Applicants should have a strong interest in Molecular Biology and submit their cv with the names of two referees as soon as possible to Dr John Brennand, Department of Biochemical Genetics Lab 5, Paterson Laboratories, Christie Hospital, Wilmslow Road, Manchester M20 9BX. (6560)F

UNIVERSITY OF LEICESTER

Leicester Biocentre

POSTGRADUATE STUDENTSHIP

Applications are invited for a studentship in the Leicester Biocentre, tenable from October 1st 1985.

The research would be in the challenging area of Molecular Biology and Genetic Engineering of Micro-organisms. The Biocentre is currently placing emphasis on exploiting this rapidly advancing technology for application to commercial processes.

Applicants should write enclosing curriculum vitae and names of two referees to: Mrs Sylvia Dexter, Secretary, Leicester Biocentre, University of Leicester, University Road, Leicester LE1 7RH. Tel No: Leicester (0533) 551234 Ext 277.

Previous applicants for this year's studentships at the Biocentre need not apply. (6598)F

BIRMINGHAM GENERAL HOSPITAL

University Department of Medicine

SERC — CASE RESEARCH STUDENTSHIP

The project is to investigate factors influencing the response of patients with chronic suppurative chest disease to antibiotic therapy. These include antibiotic penetration and ß-lactamase production and will necessitate the development of suitable immunological assay systems which will be undertaken, in part, at the laboratores of Beecham Pharmaceuticals.

Candidates should possess, or expect to obtain, a first or upper second class honours degree in a suitable subject. Three copies of the application should be sent as soon as possible to Dr D. Burnett, Clinical Teaching Block, General Hospital, Steelhouse Lane, Birmingham, Telephone: (021) 236 9922, who can also supply further information (6545)F

CONFERENCES and COURSES

An International Conference on

Methods in Protein Sequence Analysis

will be held in Seattle, Washington
August 17–21, 1986

This is the sixth in a series of conferences focused on methodological problems and progress in analyses of protein structures. Topics will include:

Fragmentation, purification and degradation techniques
Methods of microsequence analysis
Relationship of DNA and protein sequencing
Posttranslational modifications
Comparison of homologous proteins

Scientific Advisory Board

ATTENTION SCIENTISTS AND RESEARCHERS

Posters are now being accepted for BIO/TECHNOLOGY's premier conference

BIO/TECHNOLOGY

LOOKS TO THE NEXT DECADE

January 20-22, 1986, Clarion Hotel, New Orleans

You are invited to submit abstracts of work with commercial implications to:

Research Editor
BIO/TECHNOLOGY Conference
65 Bleecker Street, New York, NY 10012

Ideas suitable for support from corporate or venture funding are particularly welcome.

Conference Themes:
Day 1: The Molecular Biology of Plants & Animals
Day 2: Commercial Production Processes
Day 3: Innovations in Pharmaceuticals & Immunology

AWARDS

Die Wilhelm und Maria Meyenburg-Stiftung verleiht den

Meyenburg-Preis 1985

für hervorragende Forschungsarbeiten auf dem Gebiet der

Krebstherapie

Die Ausschreibung richtet sich an Wissenschaftler und Arzte, die in der Grund-lagenforschung der Krebstherapie oder in der klinischen Krebs-therapieforschung arbeiten.

Der Meyenburg-Preis ist mit 25 000,-- DM dotiert. Die Mittel sind zur Forderung der Forschungsarbeiten des Preisträgers gedacht

Um den Meyenburg-Preis konnen sich Wissenschaftler, die in Deutschland arbeiten, bewerben oder dafür vorgeschlagen werden. Mit der Bewerbung bzw. mit dem Vorschlag sind die Veroffentlichungen oder im Druck befindlichen Arbeiten der letzten drei Jahre, gegebenenfalls auch fruhere wesentliche Veröffentlichungen im Original sowie ein Veroffentlichungsverzeichnis einzureichen. Eine kurze zusamenfassende Darstellung der eigenen Arbeiten sowie des wissenschaftlichen Werdegangs sind beizufügen.

Uber die Preisvergabe entscheidet der Vorstand der Wilhelm und Maria Meyenburg-Stiftung. Er wird dabei von einem Gutachtergremium beraten

Der Preis wird nicht geteilt
Der Rechtsweg ist ausgeschlossen.

Bewerbungen und Vorschlage sind bis zum.

30. September 1985

zu richten an den Vorstand der Wilhelm und Maria Meyenburg-Stiftung, zu Hd. Herrn Professor Dr. K. Munk, Deutsches Krebsforschungszentrum, Postfach 10 19 49, 6900 Heidelberg.

(W1882)N

SEMINARS and SYMPOSIA

LEUKAEMIA RESEARCH FUND

International Research Symposium on
"GROWTH FACTORS, HAEMOPOIESIS AND MALIGNANCY
at Royal College of Physicians, London NW1
on WEDNESDAY 29TH MAY 1985
Registration Fee (including lunch) £15.
For programme details and registration form apply to:
LEUKAEMIA RESEARCH FUND,43 Great Ormond Street, London WC1N 3JJ, (tel: 01-405 0101)

(6555)M

ASSOCIATESHIPS

IMPERIAL COLLEGE

DEPARTMENT OF GEOLOGY
RESEARCH ASSOCIATESHIP IN MICROPALAEONTOLOGY

Applications are invited for a post-doctoral Research Associateship in Micropalaeontology tenable for three years in the first instance. The successful candidate will be required to teach at undergraduate and postgraduate levels, and to contribute to research. Salary payable will be at the appropriate point on the R & A Scale 1A with London Allowance.

Further information can be obtained from Professor J L Knill, Department of Geology, Imperial College, London SW7 2BP. Tel: 01-589 5111 ext 5501 to whom applications, with names of at least two referees, should be sent by 1 July 1985. (6522)O

CONVENIENT·INFORMATIVE·TIMELY·PROVOCATIVE

FOUR DYNAMITE REASONS WHY YOU SHOULD SUBSCRIBE TO BIO/TECHNOLOGY NOW . . .

1. You'll save time. Because you don't have time to read every journal in the field, BIO/TECHNOLOGY is written and edited to give you all the information you need in ONE convenient source. BIO/TECHNOLOGY is the only journal to give you news. Features. Original research. Product evaluations. Industrial applications. Job openings. Book and product reviews. And more. If it's important to your work, you'll find it between the covers of BIO/TECHNOLOGY.

2. You'll learn new ways to improve your on-the-job skills and run a more successful operation. Each month BIO/TECHNOLOGY gives you the scoop on invaluable start-up information . . . the latest instrumentation . . . marketing breakthroughs . . . funding sources . . . new technologies . . . patents and licences . . . profiles on how others are avoiding the pitfalls and reaping the rewards. In fact, just one practical tip from BIO/TECHNOLOGY can be worth many times the cost of your subscription.

3. You'll be up-to-date on all major industry developments. With correspondents all over the world, BIO/TECHNOLOGY delivers the inside story on who's doing what, where. You'll get the latest word on changing government regulations and tax law, and how they affect your work.

Plus you'll read original research papers by bench scientists, engineers, and biologists that will help keep you in the forefront of every new discovery worth knowing about.

4. You'll get new ideas you can put to use immediately. BIO/TECHNOLOGY lets you rub elbows with eminent scientists, tour new facilities and learn how new processes work in every field from genetic engineering to molecular biology. Each month, BIO/TECHNOLOGY helps spark ideas for your own research, for new industrial applications and for getting along in the increasingly competitive financial arena.

If you're not already subscribing to BIO/TECHNOLOGY, don't delay the moment any longer - return the coupon below and we will send you twelve issues. You risk nothing. If for any reason BIO/TECHNOLOGY doesn't live up to your highest expectations, just let us know and you'll receive a full refund on all unmailed copies. Remember too, that your subscription may be tax deductible.

TO START RECEIVING YOUR SUBSCRIPTION, FILL OUT THE COUPON BELOW AND RETURN WITH PAYMENT TO:

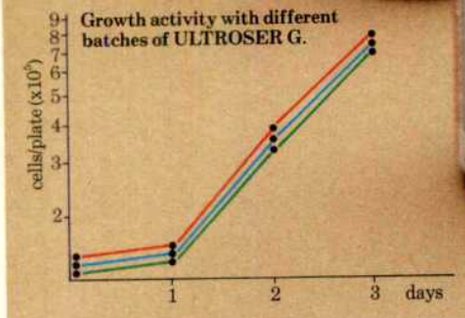
DISTINCTIVE MAMMAL-LIKE REPTILE

TISSUE CULTURE



roduct review

Serum free cell growth with new ULTROSER G

batch, after batch, after batch

ULTROSER G is a serum free synthetic growth support for multi-purpose cell culture—and cuts out the pretesting needed for fetal calf and other alternatives. As a true serum substitute, its well defined composition guarantees you batch uniformity to consistently give you regular cell development and reliable control over tissue culture variability. You'll soon find out how ULTROSER G saves you time, is easy to use, simple to store and gets you results—batch after batch after batch. With 5 times less protein than FCS to simplify purification and bioassays, and the minimal amounts needed (1—3%), you'll know why so many labs like it even more. And when you discover that it comes lyophilized, ready for use and can be kept outside a freezer, you'll want to check it yourself. Get in touch with LKB, and we'll send you the latest on how to grow cells without serum—and without problems.

Trials performed with Vero cells in HAM'S F12 culture medium supplemented with 2% ULTROSER™ G. Tests carried out by Dr. E. Boschetti at Réactifs IBF, France.

Developed and manufactured by IBF

CO_2-Auto-Zero

CO_2 zero absolutely stable

Heraeus Incubator for Cell and Tissue Cultures

B 5061 EK/CO_2, with periodic automatic CO_2 calibration

- Very uniform temperature in the working chamber
- High relative humidity
- Rapid recovery of temperature and humidity
- CO_2 control with automatic zero correction
- Correction of O_2 zero without the cultures being affected
- Not susceptible to contamination
- Simple handling
- Inner casing of stainless steel or copper, at buyer's option

A capital choice

P & S BIOCHEMICALS IN AMERICA

Now you can get the best of British biotechnology,
not only in the UK and Europe, but directly in the USA.
Simply by calling P & S Biochemicals Inc in Maryland, close to the nation's capital.

Next generation products which back your committment
to biotechnology and molecular biology.

POLYMERAiD® RH

Single strand DNA labelling system for high specific activity probes.

TRANSCRIPTAiD™ RT

cDNA synthesis system for the generation of double stranded cDNA for direct use in cloning without S1 nuclease digestion.

LiGAiD®

Fast, efficient, effective DNA ligation reagent.

Competent cells, vectors, enzymes . . . all of the highest quality available.

Make a Capital choice – call NOW and discover more:

Hot on delivery...

...cold on arrival

When you order molecular biologicals from Pharmacia you'll find we're pretty hot on delivery.

We'll dispatch your order as soon as we get it, packing it carefully in wet or dry ice.

Now our enzymes are supplied in screw cap mini vials with new waterproof labels, and will easily fit into your centrifuge tubes and freezer trays.

At Pharmacia Molecular Biology Division that's all part of the service. We realize that the success of an experiment depends on the quality of the products used and the speed at which you get them. With us you'll find that the only thing kept on ice is your product - not your experiment.

Contact us today and we'll send you our free catalog with details of over 800 molecular biologicals.

Pharmacia... your partner in molecular biology.

nature

NATURE VOL. 315 30 MAY 1985

COVER

The skull is that of a new member of the Tritylodontidae — the last of the great mammal reptiles of the Jurassic. Its distinct morphological features have clarified evolutionary relationships between members of the family and these are discussed on p.398.

Consistent Sera quality; Superior cell growth.

A commitment from REHATUIN®. The virus free Fetal Bovine Serum from Armour Pharmaceutical.

VIRUS FREE.

Our process yields a serum with non-detectable virus titers.*

CONTROLLED ANTIBODY TITERS AND ENDOTOXIN LEVELS.

We can supply REHATUIN® with low to non-detectable BVD virus antibody titers and REHATUIN® with endotoxin levels less than 1ng/mL.

*U.S.D.A. Ames, Iowa Procedure.

COMPUTERIZED CELL LINE SCREENING — SAVES TIME AND MONEY.

Our Quality Control Group has cells representing over 100 unique lines available for screening. Doubling time, plating efficiency and confluent density are determined for every lot. Sera are computer allocated by customer cell line specifications.

Computer selections assure that the sera meet your specifications — reducing your need for extensive testing.

Our sera meet or exceed U.S. government requirements. (Title 9, Code of Federal Regulations).

YOU GET QUALITY SERVICE FROM OUR SALES AND TECHNICAL SUPPORT TEAM.

Armour offers quality standards backed by an unsurpassed level of technical service and know-how.

For more REHATUIN® information call 1-800-431-4505 or write: Technical Service Manager, Biochemicals, Armour Pharmaceutical Company, P.O. Box 511, Kankakee, IL 60901.

The Armour Biochemical Division also provides Normal Calf and Horse Sera, and ENZAR®-T (sterile Trypsin solution).

GUIDE TO AUTHORS

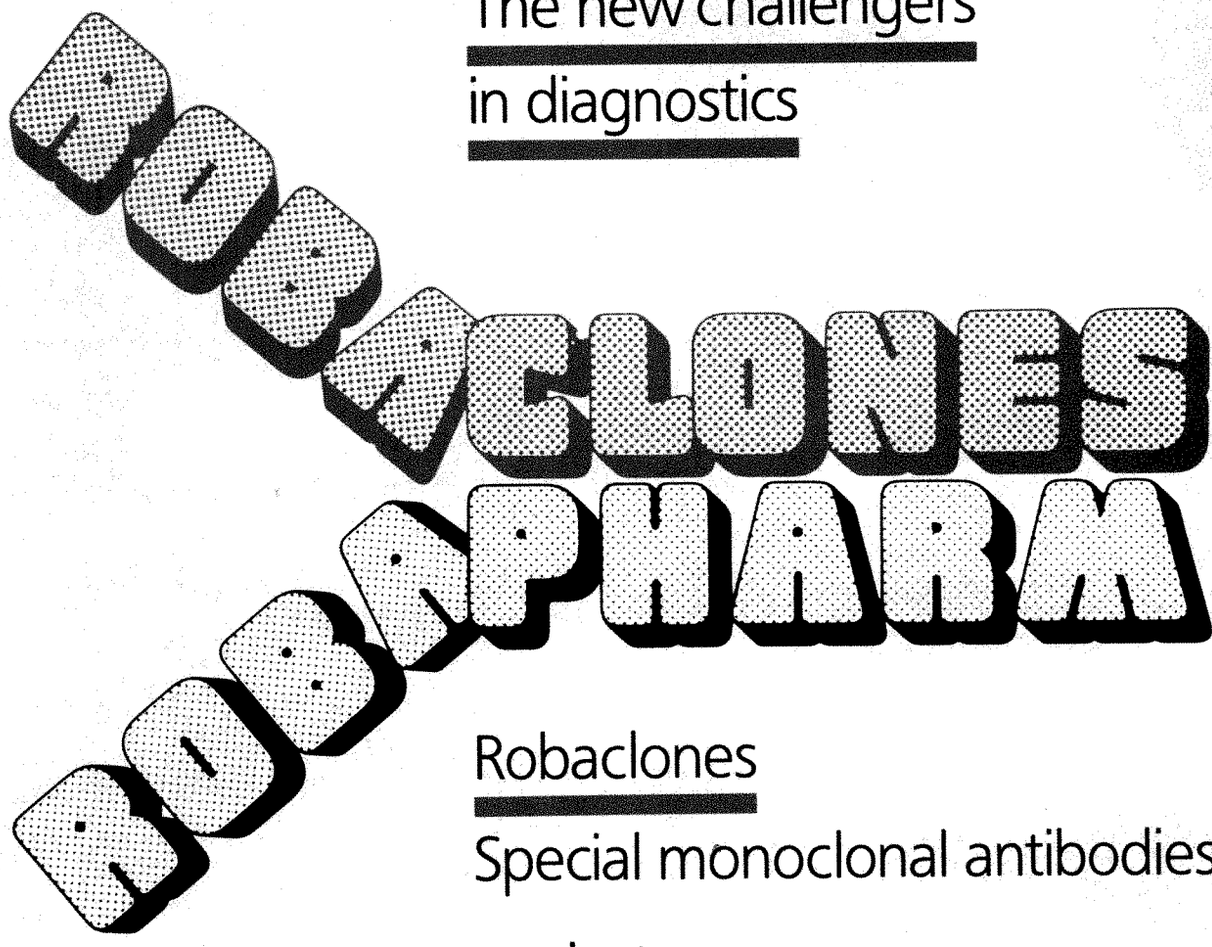
Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.



Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

The new challengers in diagnostics

Robaclones

Special monoclonal antibodies against

Endothelial cells
Smooth muscle cells
Macrophages

Robapharm has a 50 years tradition in biological research. The company today is highly active in biotechnology and provides scientists with rare monoclonal antibodies throughout the world.

These antibodies represent new tools for research on the vascular endothelium and on mononuclear phagocytes and shall be useful in diagnosis of endothelial cell tumors, pathological changes of the vessel wall (atherosclerosis) and various inflammatory cell infiltrates.

Reader Service No.66

You Work With Many Cell Types. So Does Opti-MEM™ I.

Introducing the First Multi-use Reduced Serum Medium.

Only Opti-MEM™ I supports optimal growth with reduced fetal bovine serum for a wide variety of mammalian cells. Most cells routinely cultured in serum-supplemented medium may be directly transferred into Opti-MEM™ I with a minimum of 50% reduction in serum. In addition to its versatility, many other unique features make Opti-MEM™ I the optimal choice for most cell culture needs.

High performance. Opti-MEM™ I actually *outperforms ordinary serum-supplemented media* in many applications.

Stringent testing. Opti-MEM™ I is performance-tested for cloning efficiency and growth promotion using various mammalian cell types, including murine myelomas, hybridomas and adherent cultures. In addition, Opti-MEM™ I is tested for pH, osmolality, endotoxin level and bacterial/fungal sterility.

Stability. Opti-MEM™ I has a shelf life of six months from date of manufacture.

Ease of preparation. Opti-MEM™ I is ready for use in only three steps: add 2-mercaptoethanol (included); mix thoroughly; and add fetal bovine serum.

Economy. Opti-MEM™ I not only decreases the amount of costly serum needed, it also is less expensive than most other reduced serum media.

For more information about Opti-MEM™ I, including performance data for a variety of cells, ask for our free technical brochure.

GIBCO Opti-MEM™ I, the reduced serum medium that works the way you do.

Opti-MEM™ I was developed by Hybridoma Sciences, Inc., Atlanta, Georgia.
For *in vitro* diagnostic use.

Schwarz/Mann Biotech Announces:

ACRYLAMIDE, *Ultra Pure*
Electrophoresis Grade

Our new Ultra Pure Acrylamide for electrophoresis is prepared by a recently developed three-fold recrystallization process. This new Acrylamide produces crystal clear solutions and transparent gels. The Acrylamide's performance has been checked in functional tests such as electrophoresis in Laemmli SDS PAGE gels.

Specifications:

Formula: CH_2:CH.CO.NH_2
Molecular Weight: 71.08
Purity: >99.9%
$E^{1\%}_{1cm}$ (290nm): <0.10
Acrylic Acid: <0.001%
Insoluble matters (in H_2O): <0.001%

Our **NEW** Biotech Catalog is now available. Request your free copy today.

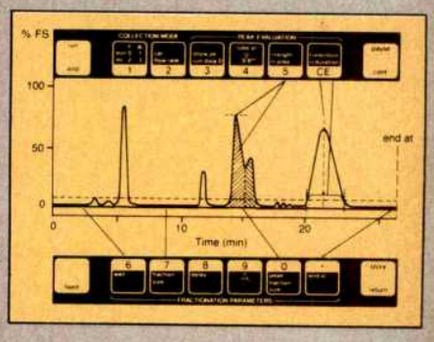
Everything rolled into 1



Pharmacia's FRAC-100 fraction collector

Do you need a simple inexpensive collector or the most advanced programmable fraction collector – get both with the FRAC-100.

Do you need fast tube changes and microliter collection volumes or is it 20 ml fractions from a 2 liter column? The FRAC-100 does both.

Do you need data handling and integration capabilities or do you want to choose from eight different collection modes and six fractionation parameters? The FRAC-100 does both.

Your everything solution in fraction collection is from Pharmacia.

Contact us today.

The Standard:

For over 10 years researchers have recognized HyClone "defined" sera as the standard by which quality sera are judged. HyClone is the only sera with all of the following advantages:

- Low levels of endotoxin
- Low levels of hemoglobin
- Triple 0.1 um filtration
- Over 200 biochemical assays
- Protection against photooxidation

HyClone defined sera are available in: fetal bovine, calf bovine, and equine.

Electro Cellfusion

A universal and highly efficient method to fuse biological cells and to transfer material through the membrane.

Cellfusion system CFA 400, licensed by KFA-Juelich/FRG

We offer superior hardware for all popular fusion techniques (microprocessor controlled) and various proven fusion chambers at an unmatched price.

The fusion process shown with oat protoplasts (Dr J. Vienken, KFA)

Some actual success reports of electro cellfusion:

- Hybridoma fusion and isolation of stable clones*
- DNA transfection**
- Fusion of yeast protoplasts and following cultivation*
- Fusion of plant protoplasts and following regeneration of a complete plant**

*published **ready to publish

Ask our Dr W. Asche for more details and get your free copy of our comprehensive literature list.

We shall be exhibiting and demonstrating electro cellfusion at:

BIOTECH 85, Geneva: 21-23 May, Booth 47-52
ACHEMA 85, Frankfurt: 9—15 June, Booth 6 I/E19

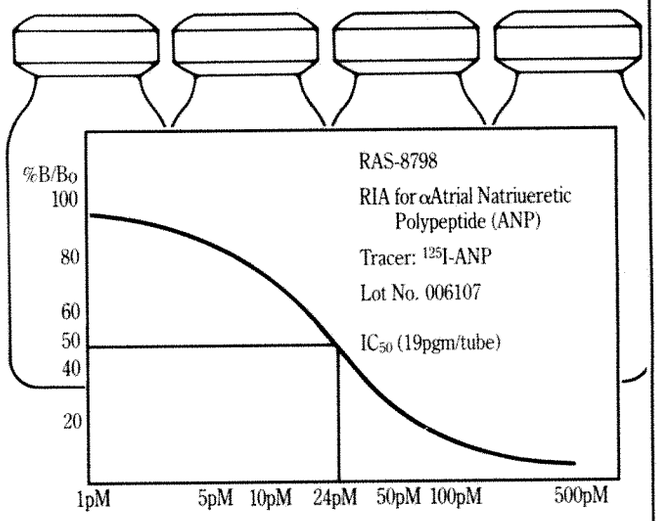
RADIOIMMUNOASSAY KIT FOR ALPHA-HUMAN ATRIAL NATRIURETIC POLYPEPTIDE

This kit is designed to measure specifically alpha-human atrial natriuretic polypeptide (alpha-hANP) and its related peptides by a competitive radioimmunoassay. It is intended for in vitro protocols only. The antiserum used for this assay was raised against synthetic alpha-hANP.



This kit contains sufficient reagents for 125 RIA tubes.

Catalog #RIK 8798

Sensitivity:
IC^{50} 19 pgm/tube

Specificity:

Peptide	% Cross-Reactivity
human αAtrial Natriuretic Polypeptide	100
rat ANP	100
ANP (8-33)	90
rat ANF (13-28)	50
rat Atriopeptin III	100
rat Atriopeptin II	27
ANP (18-28)	57
rat Atriopeptin I	3
Somatostatin	0
Oxytocin	0
Arg^8-Vasopressin	0

Contents:

- Triton X-100/water
- RIA buffer (powder)
- Standard alpha-hANP (lyophilized powder)
- Rabbit antiserum specific for alpha-hANP (lyophilized powder)
- ^{125}I alpha-hANP (lyophilized powder)
- Goat anti-rabbit IgG serum (lyophilized powder)
- Normal rabbit serum (lyophilized powder)
- Instructions/flow sheet for the RIA protocol
- Instructions for calculating the results and graph paper for plotting the results.

Peninsula Laboratories results show plasma levels of ANP-like immunoreactive material from rat plasma to be 444 +/− 160 pgm/ml +/− SD (N = 12)

CAUTION:
Investigational Device. Limited by federal law to investigational use.

Arms control.

λgt 11 Arms

Expression Cloning. The λgt 11 Cloning Vector has been digested with EcoRI and dephosphorylated. It accepts 0 to 7 Kilobase EcoRI inserts.

Kits contains strains Y1088, Y1089, Y1090 and a test insert. Efficiencies are greater than 10^7 recombinants per microgram of λgt 11 Arms using Gigapack™ packaging extract.

λgt 10 Arms

Genetic Selection. The λgt 10 Cloning Vector is suited for the cloning of EcoRI ligatable DNA fragments that range between 0 and 7 kilobases. Kits contain strains C600 and C600 Hfl+ and a test insert. Efficiencies are greater than 10^7 recombinants per microgram of λgt 10 Arms using Gigapack.

EMBL3 Arms

Large Insert, Genetic Selection. The EMBL3 Cloning Vector is one of the most versatile and efficient lambda-based vectors available today. Its advantages include the ability to accept BAM HI ligatable inserts (i.e. Mbo I, Sau 3A, Bgl II or BAM HI inserts up to 22kb in length), strains Q358, Q359 and a test insert are provided. Efficiencies range between $2X10^6$ and $8X10^6$ recombinants per microgram of EMBL3 Arms using Gigapack packaging extract.

λgt 11, λgt 10 and EMBL3 Cloning Vectors save valuable time and have been expressly processed to be extraordinarly effective, reliable and inexpensive. Simplicity in protocol make Vector Cloning Systems products a convenience to work with.

Pharmaceutical Medicine

A New Journal

A new, independent, quarterly journal for the critical assessment of new and old methods employed to test drugs in man. To promote the discipline of pharmaceutical medicine and cover those activities germane to human testing of drugs, papers will appear on human pharmacology, clinical investigation, comparative clinical trials, and epidemiological studies. The latter will inevitably be associated with drug safety and post-marketing surveillance. The problems of quality control and analysis of laboratory tests will be addressed, and the handling of clinical trial data. The design and statistical analysis of clinical studies will also feature.

Pharmaceutical Medicine will provide invited contributions, reviews, news and opinion. A major feature will be abstracts of papers published elsewhere giving new means of assessing drugs.

The Journal will not take an overtly political or commercial position, but any matters affecting ways and means of assessing drug efficacy and safety, including governmental regulations, will be discussed.

Subscription Rates
UK and Eire: £45.00, USA/Canada: Surface US $95.00, Rest of World: Surface £63.00

NEW

IUPHAR 9th International Congress of Pharmacology Proceedings

* Proceedings of the leading international meeting for pharmacologists and toxicologists
* 21 plenary lectures and 180 papers from the 30 symposia, published in three volumes
* An essential compendium of the topics of high interest in drug research today
* **Available November 1984**

3 Volume Set £145
(ISBN 0 333 368908)
Single Volumes
£51 each

Now published by Macmillan Press

Postgraduate Medical Journal

A monthly Journal published by Macmillan Press on behalf of the Fellowship of Postgraduate Medicine. The Fellowship was founded in the early 1900's to assist medical postgraduates by publishing Original Papers on subjects of current clinical importance together with Review Articles containing extensive, up-date bibliographies as guides to further reading. Several single topic symposia, written by specialists within that discipline, are published each year. These features combined with Current Surveys of clinical problems, Case Reports and Book Reviews, provide a unique, regular compendium of clinical medicine invaluable to the graduate in training.

Subscription Prices

Rest of World £72.00 surface, £90.00 airmail,

British Journal of Pharmacology

Published monthly on behalf of the British Pharmacological Society, the British Journal of Pharmacology contains original papers submitted from all parts of the world making it one of the most respected journals for all those professionally involved in the pharmacological sciences. It contains up-to-date papers of the highest quality on all aspects of drug action and is thus a vital source of information for physiologists, clinicians, immunologists, molecular biologists and biochemists as well as pharmacologists.

Subscription Prices
UK £155.00, USA/Canada US $390.00 surface, US $475 airmail, Rest of World £175.00 surface, £225.00 airmail.

The British Journal of Cancer

Published monthly on behalf of the Cancer Research Campaign, The British Journal of Cancer is one of the leading cancer journals in the world, publishing articles in all the major scientific disciplines relevant to the subject. The journal provides papers and short communications submitted by scientists from countries throughout the world. In addition, the Proceedings of the meetings of the British Association for Cancer Research are regularly published in the journal. From time to time other selected national and international meetings are also covered. Up-to-date book reviews appear in each issue.

Subscription Prices

JOIN US

at Nature's fourth international conference, to be held at the Novotel London, June 25th-27th, 1985

NEW TECHNOLOGY in BIOTECHNOLOGY

In the past five years, even the enthusiasts of the new biotechnology industry have often been surprised at the speed with which new opportunities have emerged. The initial focus was on the use of *Escherichia coli* for manufacturing polypeptides and proteins.

NOW...

- other bacteria as well as yeasts are also being used and attention is turning to mammalian and plant cell systems.
- improvements to the polypeptides and proteins produced are being achieved by deliberate mutagenesis of the genes introduced into the cells.
- new strains of plants and animals are being established from engineered embryonic cells.
- the manipulation and production of monoclonal antibodies and enzymes are becoming ever more refined and the goal of representing a large protein by a much simpler peptide is within reach.
- progress is being made in coupling biotechnology to electronics, so producing sophisticated measuring devices.

As in the past, these developments spring from basic research at academic and, increasingly, at industrial laboratories.

THE OBJECTIVE of this *Nature* conference (the second to be held in Britain) is to provide a survey of the recent research that will influence the evolution of biotechnology in the next few years.

THE SPEAKERS have been chosen for the originality of their own contributions to these topics, but they will also provide a survey of recent work related to their own immediate interests.

THE FORMAT of the conference will provide ample opportunity for discussion—each formal presentation will be followed by a question period, and there will also be appropriate round-table discussions.

PARTICIPANTS in the conference will be provided in advance with a selection of reading matter intended to provide background to particular talks.

DON'T MISS THIS OPPORTUNITY

to catch up with
New Technology in Biotechnology

CONFERENCE PROGRAMME

Day 1 Tuesday, June 25th

MORNING

Enzymes, immunogens
Dr. D. Thomas, Université de Technologie de Compiègne.
Dr. G. Winter, MRC Laboratory of Molecular Biology, Cambridge.
Dr. A. Klug, MRC Laboratory of Molecular Biology, Cambridge.

AFTERNOON

Antibodies
Dr. J. Birch, Celltech Ltd., Slough.
Dr. M. Neuberger, MRC Laboratory of Molecular Biology, Cambridge.
ROUND TABLE DISCUSSION

Day 2 Wednesday, June 26th

Biosensors
Dr. M. Flanagan, University College, London
Professor I.J. Higgins/Dr. A. Turner, Cranfield/Leicester.
Micro-organisms
Dr. S. Emtage, Celltech Ltd., Slough.

Micro-organisms continued
Professor D. Hopwood, John Innes Institute, Norwich.
Dr. B. Carter, Searle R&D, High Wycombe.
ROUND TABLE DISCUSSION

Day 3 Thursday, June 27th

Mammalian systems
Professor P. Tiollais, Institut Pasteur, Paris.
Dr. A. Levinson, Genentech, San Francisco.
Dr. R. L. Brinster, University of Pennsylvania

Plants
Professor M. Fowler, Wolfson Institute, Sheffield.
Professor J. Schell, Max Planck Institut, Köln.
ROUND TABLE DISCUSSION or FINAL TALK

POSTER SESSIONS will be held each day. Those wishing to present a brief account of their own work should contact Dr. Peter Newmark, Deputy Editor, Nature, 4 Little Essex Street, London WC2R 3LF, U.K.

SPACE IS LIMITED
REGISTER NOW!

TO REGISTER, return the form below with your cheque or authorised purchase order from your organisation TODAY! Applications are accepted only on completion of a booking form. We ask you to complete *one form per person.* We cannot guarantee to accept applications received after June 3rd, 1985.

THE FEE is just £170 plus VAT for the duration of the conference or £74 plus VAT per day. This includes entrance to all sessions, mid-morning coffee, afternoon tea and advance reading material. Applications without payment will be acknowledged but will not be *confirmed* until payment is received. In cases where a participant is being sponsored by an organisation, the organisation will be invoiced and once payment has reached us the participant will be sent confirmation of his or her place.

THE SETTING is London's NOVOTEL, situated conveniently within easy reach of the City's most famous sights and also the West End which boasts some of the world's best shopping and entertainment. It is also close to the main road into London from Heathrow Airport.

ACCOMMODATION has been reserved in the NOVOTEL and elsewhere for conference participants. A booking form will be sent to you as soon as we receive your registration.

THE CONFERENCE DINNER will be held on Wednesday, June 26th. This is always a popular event and SPACE IS LIMITED so make your reservation on the form below today. The cost will be £15.65 plus VAT.

AN INTERNATIONAL EXHIBITION will be held in conjunction with the conference.

NOTE: Cancellations received before May 27th, 1985 will be refunded less a processing charge. No refunds can be made after this date.

TO REGISTER FOR THE CONFERENCE, please return this form with your payment to: DEBORAH JONES, Conference Administrator, Macmillan Conferences & Exhibitions, 4 Little Essex Street, London WC2R 3LF, U.K.

Second Generation
PATCH/WHOLE CELL CLAMP

Unique new technology enables you to measure single channel and whole cell currents using one headstage—one experimental set-up lets you work with patches and cells up to 50 μm.

Instrument noise is so low that it eliminates the electronics as a source of experimental noise.

The EPC-7 is the second generation clamp design by Prof. E. Neher and Dr. F. J. Sigworth of the Max Planck Institute. It is state-of-the-art technology derived from years of pioneering experience with the practical application of patch clamps.

- Internal Resistance Switching 50GΩ-500 MΩ
- 100 KHz Bandwidth
- Integrated Series-Resistance and Transient-Cancellation Function
- Noise is 0.05pA RMS at 1 KHz
- Built-in Noise measuring meter
- ...And More

There is nothing else that even comes close...

REDUCE BACKGROUND

With Sequencing Grade Triphosphates From Pharmacia

Ultrapure Deoxynucleoside Triphosphate Solutions

While often overlooked, high quality triphosphates can increase gel clarity considerably, allowing reading of up to 30 % further from a single primer site. Pharmacia's solution triphosphates are the most stable, homogeneous and diphosphate free available, and can be used without weighing, neutralization or concentration determination.

2′,3′-Dideoxynucleoside 5′-Triphosphates

Ever since we provided the first commercial dideoxynucleosides in 1977, researchers have relied on our ultra-pure 2′,3′- dideoxynucleoside 5′-triphosphates for the specific chain termination and low background needed in their sequencing.

Keep your results clear of the background.

NATURE VOL 315 30 MAY 1985

More crisis for UK research

Now it seems that Britain will stay in high-energy physics for the time being, high-energy physics has an obligation to mitigate the squeeze on general research.

THE Kendrew committee, which has been looking into British membership of CERN, the European nuclear physics laboratory at Geneva, seems about to create a dilemma for everybody in sight — the British Science and Engineering Research Council, which pays the British subscription, the Advisory Board for the Research Councils, which has just presented the British government with a demand for extra cash, and even the management of CERN, the essence of the committee's conclusion seems to be that Britain should not immediately pull out of the European high-energy physics club, but instead demand that the cost of membership should be reduced from the end of this decade, when CERN will be equipping with superconducting magnets the electron collider now being built. Precisely what the committee thinks should happen if these negotiations come to nothing should be clear when its report is published. It will be particularly valuable to know why the committee has decided against withdrawal. Is high-energy physics after all worthwhile, or is it merely that the British research community will need the best part of five years to win what it can from past investment in CERN?

That the outcome is a compromise will be an embarrassment. Although high-energy physics is a steadily shrinking part of the budget of the Science and Engineering Research Council, it is still uncomfortably large. Last year, the advisory board was saying that the research council might have to withdraw from some whole field of science if the squeeze persisted. The Kendrew committee sprang from the sense that high-energy physics, the most conspicuous target for economizers, is too important to be abandoned just like that. The chief consequence of the Kendrew compromise is that there is no immediate prospect of relief. The reappraisal of all activities that has occupied the research council for the past six months will have to continue. Nor will there be much comfort in the recent guileful letter to Kendrew from Dr Jeremy Bray, the Labour Party spokesman on science and technology, pointing out that a future government might have different views about science budgets.

Speculations prompted by that kind of prospect are neither here nor there. Any British government would find itself in the same plight on public spending as does the present. Extra money for research, such as the advisory board has now asked for (£10 million extra next year and in each of the two succeeding years) would have to come from the British government's present spending programme. It would have been more interesting, but dangerous, if the Kendrew committee had resolved flatly to say that the research community cannot afford high-energy physics out of the present budget, and had thrown the onus of grappling with the consequences onto the government.

The advisory board, whose role is to divide the science budget each year, will now be particularly under stress, if only because some of its members are at best agnostic on high-energy physics. But continued membership of CERN squares badly with economies being made elsewhere. Out of a total budget of £631 million, the research councils will have to spend £9 million this year and £11 million next year on persuading research people to retire early. That is simple waste. The advisory board is also acutely aware, to judge from this year's submission to the government, that its own economies will have to take effect before there can be much change in the pattern of spending within the universities on the support of research, which is estimated (a little optimistically) to be worth £550 million a year. Only in the academic year beginning in 1986 will there be the first signs of how the budgets of individual universities will be changed to take account of the importance attached to the research they do. So the muttering has begun that part of the university budget should be handed over to the research councils, which is a recipe for setting academics at each others' throats.

This is where the physics community, and the management of CERN, can help. Both have in the past been dealt with generously, and may by now have earned an obligation to do something for fields more recently made vigorous. The truth about CERN is that it is every bit as splendid a laboratory as its founders intended. It is a model of international collaboration, and it is successful in the work it does. For the past decade, conscious of its cost, the laboratory has also managed to keep ahead technically by finding the money with which to build a new accelerator by closing down an older machine, or by using it as a component for a larger one. But the laboratory has some defects. It has a larger permanent staff than might otherwise be necessary, perhaps because it is international. Much worse, it happens to be in Switzerland, one of the most prosperous countries in Western Europe and that which determines what people working there are paid. Nobody suggests that the new electron accelerator should be moved somewhere else (which would be impossible) or that people working at CERN should be underpaid, but this privileged laboratory should now help solve the problems that have arisen in Britain, and even elsewhere.

What can CERN do? Economizing is an obvious must, but cheeseparing would not save anything like as much as Kendrew appears to be looking for. Broadening the base of collaboration on the second phase of the electron collider is a much better course to follow. Neither the United States nor the Soviet Union is at present a paying member of the club, even though people from each country work on CERN collaborations by a kind of gentlemen's agreement, on the ground that reciprocity eventually accrues. Why not now formalize these arrangements? If CERN has shown that European collaboration in high-energy physics works, why should it not use its present position on the crest of a wave of success to show that international collaboration can also succeed? With the US Congress in the thick of trying to reduce the US budget deficit, this might be just the time for such a move. One of the curious ironies of this field, over several generations of particle accelerators, is that the practitioners are forever saying that machines will eventually have to be built and operated internationally — but not just yet. □

Biological manuscripts

From the beginning of next week (20 May), Miranda Robertson, Biological Sciences Editor of *Nature*, will be based in the Washington office of *Nature*. Manuscripts offered for publication may be sent, as at present, to either the London or the Washington office; with the benefit of good communications, the speed with which manuscripts are dealt will be independent of the place at which they are received. But authors are asked please in future to send **four copies of manuscripts** intended for publication (one for each office and two for referees). □

US universities

Task force quests for financial wizardry

Washington

THE Congress's Science Policy Task Force was told last week that between $5,000 million and $20,000 million might be needed to bring US university research facilities up to acceptable modern standards, and that the existing partnership between universities, industry and government "may not be adequate" for the task. While the general sentiment has been heard before on Capitol Hill, this particular warning was surprising because it was uttered not by some university president making a cap-in-hand appeal for a new laboratory, but an assistant director of the White House's Office of Science and Technology Policy, Dr Bernadine Healy.

In two days of hearings on "government and the research infrastructure", the task force heard a variety of prescriptions for improving universities' access to state-of-the-art equipment. In Healy's view, both government and universities must take their share of the blame for the accumulated deficit of research hardware. Universities, she said, have often behaved like dependants of the government, "abdicating their responsibility for infrastructure and biding their time until federal facilities and programmes were resumed". The government, for its part, has "attempted not to invest in the research enterprise, but to procure packets of research results at the lowest possible prices".

The Science Policy Task Force, a bipartisan group established within the House of Representatives' Committee on Science and Technology, has been hearing from witnesses in government and academic life since mid-April. The hope is that a preliminary report will be completed by May next year, with a final version available the following October. Witnesses so far have fallen into two clearly defined camps: those who believe that the present system for provision of research facilities is working well, and those who feel that catastrophe is imminent.

The latter group argues that universities grew accustomed to 15 per cent annual increases in their operating research budgets during the heady 1970s, and even during the early years of the first Reagan presidency. As long as the hefty increases continued, universities were cushioned from the effects of the lack of investment in buildings and large items of equipment: most of the federal programmes specifically geared to improving research infrastructure had dried up in the early 1970s. Now that the days of 15 per cent annual increases are seemingly over, the price of years of underinvestment in the infrastructure will have to be paid.

Healy, speaking with the advantage of inside knowledge of the White House's soon-to-be-completed study of the universities chaired by David Packard, said that a multi-billion dollar programme might improve conditions, but that changes in attitudes would also be needed to put things to rights. Specific proposals include the following:

- the proportion of the $20,000 million civilian research and development budget spent in universities should be increased above its present level of 30 per cent;
- unrestricted donations of equipment and contributions to renovations should be encouraged (presumably by favourable tax exemptions);
- amortization periods for both equipment and buildings assumed in federal grants should be reduced from their present unrealistically high levels (50 years and 15 years respectively) to something closer to reality (say, 20 years and 6-8 years);
- and (as a strong hint) the government should stop trying to "micro-manage" equipment purchases and reduce the burden of excessive documentation.

The need for innovative financial approaches was echoed by Dale Corson, chairman of the government/university/industry research round table sponsored by the National Academies of Science and Engineering. Corson asserted that obsolescence of research instruments is limiting productivity, and that in engineering, in particular, this state of affairs is increasingly driving away potential recruits into the field.

Corson argued that the problem has arisen largely because of the increased cost of research instruments; he proposed that more use should be made of shared facilities and that more facilities should be financed jointly with state governments. Besides exploring new ways of providing equity, the traditional form of financing for research facilities, universities should also look at new ways of debt financing. Corson asked for the removal of legal obstacles that, in essence, prevent the promise of federal grants from being used as collateral against loans.

Summing up in a virtuoso exhibition of Washington bureaucratese, Corson asked that these initiatives be brought together in a national programme that will "regularize the facilities appropriation process" and will "leverage federal funds to the maximum degree possible". Corson's proposal will doubtless be aired in July at a conference on academic research facilities sponsored by the government/university/industry research round table and federal agencies.

Tim Beardsley

Growth hormone

FDA ban on pituitary product

Washington

FEARS that growth hormone extracted from human pituitary glands may spread the rare neurological condition known as Creutzfeldt-Jakob disease (CJD) have prompted the US Food and Drug Administration (FDA) to stop the use of all human pituitary products. Those most immediately affected are the 2,500 hypopituitary dwarfs in the United States, who depend on the hormone to maintain normal rates of growth; clinical research on other pituitary products has also been suspended. FDA is now under strong pressure to approve the general use of a recombinant human growth hormone product manufactured by Genentech Inc. that has been under FDA review for the past 18 months.

The two commercial companies that have now withdrawn their human-derived growth hormone products, KabiVitrum and Serano Laboratories, point out that the evidence against them is at best indirect. There have been three recent deaths attributed to CJD; among young men who received crude pituitary extracts as children; suspicions were aroused because the disease is normally found only in those over 40. Only one diagnosis has been confirmed, however, and no autopsy was carried out on one of the suspected cases. In the other two cases, there are other complicating factors that could explain infection by a slow-acting virus such as that believed to cause CJD; one was a diabetic who received frequent insulin injections, for example.

The deaths occurred among patients who had been treated under the National Hormone and Pituitary Program of the National Institutes of Health (NIH). Since the programme started, the purification methods used have improved markedly, and all growth hormone manufactured since 1977 has been through a final stage of column chromatography using Sephadex. The commercial manufacturers, who also use column chromatography, point to a study by Professor A.G. Dickinson of the University of Edinburgh which indicated that virus deliberately introduced into pituitary tissue was not detectable after the column chromatography stage of purification.

One argument against a link between CJD and growth hormone is that the hormone is produced in batches that are used to treat several hundred children. Even if only one batch had been contaminated, therefore, many more than three cases would be expected. There are not known to be any living growth hormone recipients with CJD symptoms, and a recent survey of 300 recipients in Switzerland found no cases of CJD.

Erol Caglarcan of Serano accuses FDA of using "unnecessary pressure" and says the Serano product, which has the trade name Asellacrin, will still be used outside the United States. Serano hopes in time to market a genetically engineered growth hormone being developed by Celltech in England, but that product is not yet at the stage of clinical trials. KabiVitrum's recombinant product, developed under licence from Genentech, is already in clinical trials in Europe: the company is correspondingly less concerned about FDA's action in banning human growth hormone.

The pressure on FDA to approve Genentech's recombinant product as quickly as is seemly arises because testing the pituitary samples for presence of the CJD infective agent has to be done by bioassay, using squirrel monkeys or chimpanzees. Besides being expensive, results of tests now being mounted by NIH will not be available for two years. In any case, negative results from such tests would not provide much reassurance, given that so little is known about the disease. If Genentech's product can be shown to be safe, FDA might be tempted to abandon pituitary-derived growth hormone permanently.

A decision to abandon pituitary products would, however, affect other substances besides growth hormone. Dr A.F. Parlow of the University of California at Los Angeles, who has supplied pituitary products to NIH since 1977, is concerned that research into other pituitary hormones could be set back; clinical trials of prolactin and thyroid-stimulating hormone, for example, have had to be put on ice. Parlow believes that FDA will have to embark on a convincing demonstration that viruses can be effectively excluded by modern purification methods in order to prevent a complete halt in pituitary research.

Genentech first produced a recombinant growth hormone product several years ago, but — perhaps because of the ready availability of the human-derived product — progress towards FDA approval has been slow. The Genentech hormone has an extra methionine residue tagged on that is not found in the natural substance, and in early clinical trials many patients developed antibodies to the product.

Last year, FDA asked Genentech to provide further safety data on a trial population to be monitored for a full year; that study is now under way but the data requested by FDA will not be complete until the start of 1986 at the earliest. Recently, however, FDA officials have been saying publicly that the Genentech product, which has now been improved, is likely to be approved within the next two or three months

Genentech, for its part, is playing it cool, saying the decision is entirely up to FDA; a recombinant growth hormone without the extra methionine is also believed to be in the pipeline. **Tim Beardsley**

French science budget

Fabius goes for growth

M. HUBERT Curien, French minister for research and technology, at last has his figures.For the past few weeks he has been waiting to hear from the Prime Minister, M. Laurent Fabius, how much money there is in the kitty for French research for the next three years, to put some substance in his "three-year plan" for research — an instrument which parliament must vote on and which should give a new impetus to the political emphasis on science in France. The Prime Minister's answer is four per cent real growth per year in civil research and development spending to 1988, excluding defence research spending.

And that is just the government side. There will also be increased incentives to industry to carry out research (a doubling of tax allowances on research and development budgets) which will give industry another FF 600-700 million (£60-70 million) a year to spend, so that overall it is estimated that French national research and development spending will rise over the next three years from 2.25 per cent of gross national product now to 2.6 per cent in 1988. At its nadir in 1979-80, this fraction had touched 1.8 per cent.

Thus the growth in French research spending should continue, provided there are no global budget "corrections" in future, corrections which rather reduced the true impact of the ambitious "law for science" introduced in 1982 by M. Curien's predecessor, M. Jean-Pierre Chevènement. But Chevènement also increased the number of jobs for scientists, and this trend is to continue. While British research councils have lost around a fifth of their posts since 1981, their French counterparts have gained something around 3 per cent a year. Curien's plan offers 1,400 new jobs for scientists over the next three years, less annually than last year's 1,000, but still a substantial figure.

So where are the French after all this attention to science? Doing fairly well, but could do better, particularly in industry, is the informed verdict in Paris.

Briefly, the tally is thought to be this. First, a reversal of the decline of support for French science in the 1970s. The decline was brought about initially by President Pompidou's massive indifference, and continued by successive administrations until Pierre Aigrain, science minister under President Giscard d'Estaing, reversed the trend. Second, M. Chevènement, under President Mitterrand, made science a political touchstone, and changed the whole French political mentality towards science, and of scientists towards industry. Third, the research councils — such as the Centre National de la Recherche Scientifique (CNRS) with its 10,000 scientists — were accorded looser legal ties, which allowed them to make profitable associations with industry, set up affiliates and so on. And fourth, science and technology were given weight, and budgets, in the regional administrations of France, which gave an opportunity for a more flexible response to local industrial and social needs. A fifth bonus, the new impetus given to universities to compete with one another for students and research cash, has come too late to yet have any real impact.

Failures, however, include a poor response from industry, too much centralization of decision-making and too little realistic assessment of the successes and failures of the policy.

There is hope, however, that Curien will be able to correct many of these failings. The new three-year plan, agreed at ministerial level but not yet voted upon, is one of his instruments. A practical man, Curien seems to be taking many of the right steps to put the rebirth of French science back on course. **Robert Walgate**

Australia's NDP in disarray

Canberra

AUSTRALIA's single-issue Nuclear Disarmament Party (NDP), whose 8,000 members include many former Labor Party supporters disaffected by the Hawke Labor government's decision in June last year to mine and export uranium, has lost its only parliamentary representative-elect, Ms Jo Vallentine, who resigned last week, announcing that she would set up a new anti-nuclear political party to be known as Peace and Nuclear Disarmament Action (PANDA).

This move follows NDP's first national conference in Melbourne last month in which Senator-elect Vallentine, former Labor Senator Ms Jean Melzer and narrowly-defeated NDP Senate candidate and rock singer, Mr Peter Garrett, staged a walkout, claiming that NDP was in danger of falling under the domination of entryist members of the Socialist Workers Party, a Marxist grouping of Trotskyite tendency. The conference was to have given some direction to NDP policy, because the party had only six months to organize before last December's half-Senate elections.

One of the chief reasons given by the breakaway group for leaving NDP was the party's "infiltration" by people who were already members of other political parties: their proscription is likely to be a feature of membership of PANDA. The members of Ms Vallentine's West Australian branch of NDP were canvassed by a postal ballot that ended in a vote to cut all ties with the national body and form a separate party. Breakaway groups in most other states are holding similar ballots whose results will be known next month. Jeffrey Sellar

US investment

Universities and South Africa

Washington

THIS spring has brought to many US college campuses demonstrations, reminiscent of the 1960s, against apartheid in South Africa. With the demonstrations has come a reconsideration of an old issue: should universities invest in companies that do business in South Africa?

According to several recent surveys, fewer than a dozen universities have completely divested themselves of holdings in such companies. And even as pressure mounts to divest, a new study by the Investor Responsibility Research Center, an organization founded 13 years ago to provide institutional investors with information on the ethical behaviour of corporations, may stiffen the resolve of those university boards that have resisted so far: according to the report, "divestment will have a detrimental effect over the long term on portfolio performance".

Most of the hundred or so universities that have taken some action on investments in South Africa, mostly in response to protests in the early 1970s, have adopted policies of partial, selective divestment, usually selling off stock in companies that fail to adhere to the so-called Sullivan principles. These rules, developed by Reverend Leon Sullivan of Philadelphia, a member of the General Motors board of directors, prescribe basic fair employment practices for companies operating in South Africa. The universities that have opted for partial divestment argue that a selective policy is the best method of influencing corporate behaviour; with across-the-board divestment, influence is lost.

Those calling for total divestment now say that this selective policy simply has not produced results. According to a recent survey by the American Council on Education (ACE), only about 100 of the 350 US companies operating in South Africa adhere to the Sullivan principles; and in any case there is no evidence that other foreign companies or South African companies have been influenced by the example of these 100. Bishop Desmond Tutu, who won the Nobel peace prize for his stand against apartheid, has called for a more stringent set of principles: companies in South Africa should recognize black labour unions, invest in black education and training, and should freely hire blacks without regard for the country's restrictive laws governing the movement and residence of the 24 million South African blacks.

The most militant protests this spring have taken place at Columbia University and the University of California at Berkeley, both of which already have policies of partial divestment. Students have occupied buildings and there have been a number of arrests.

And while both of those universities have agreed to reconsider their policies, others are being more outspoken in their belief that the chief responsibility of university financial administrators is to make money for the university. Derek Bok, president of Harvard, which has maintained a selective divestment policy since 1981, spoke for many when he said recently: "Despite our revulsion toward apartheid, the fact remains that Harvard's resources were entrusted to us for academic purposes and not as a means for demonstrating our opposition to apartheid or to other manifest injustices and evils around the world." The ACE survey noted that even among those universities choosing total divestment, the justification was that colleges "should not benefit from corporate practices that cause social injury"; they rejected the notion that they were taking a political stand.

US investment in South Africa is estimated at $14,000 million. About one-third of the companies on Standard & Poor's 500-company stock index do business in South Africa.

Besides the efforts on campus, a number of states and municipalities have ordered divestment. A bill now before the US Congress would ban bank loans and computer sales to the South African government.

Stephen Budiansky

Major universities that have divested stock in companies operating in South Africa

	Policy	Value of stock divested	Year action taken
Boston University	Partial	$6 6 million	1979
Brown University	Partial	4.6	1984
City College of New York	Total	7.1	1984
Columbia University	Partial	2 7	1979

Age discrimination alleged

Washington

HOFFMANN-La Roche employees laid off earlier this year in what the company described as an austerity measure have sued, alleging age discrimination. The suit, so far joined by 250 laid-off workers all over age 40, accuses Roche of pursuing a deliberate policy of singling out older employees for dismissal. More than 1,000 employees were dismissed in a move to save $50 million a year for the next five years. Lawyers for the plaintiffs say that as many as 600 of these employees could be eligible to join the suit, which they hope to have certified as a class action.

The suit also alleges that the company's policies governing promotions, transfers and assignments favour younger workers at the expense of those over 40.

Federal law prohibits age discrimination in employment. Companies that violate the act are liable for back pay, compensation for loss of future earning power, attorneys' fees, and, if "wilful" violation of the act can be shown, double damages.

Leonard Flamm, an attorney for the plaintiff, says that most of the layoffs occurred at Nutley and Belvidere, New Jersey.

Hoffmann-La Roche says that it intends to defend all such lawsuits brought against it and maintains that all decisions to terminate employment were "nondiscriminatory". No date has been set for preliminary hearings. Stephen Budiansky

Japanese psychiatry

Abuse for visiting scientists

Tokyo

WESTERN research workers studying such topics as neurotransmitter receptors and the mode of action of antidepressants are not used to being thought of as brutal oppressors of society, nor do they conduct research in fear of assault. But, as two visiting lecturers found recently, for workers in these fields there are real dangers in Japan.

The two lecturers, Tim Crow of the Clinical Research Centre in the United Kingdom, and D. van Kammen of the University of Pittsburgh, were due to give talks on "Genes and viruses in schizophrenia" and "Episode markers in schizophrenia" at the seventh congress of the Japanese Society on Biological Psychiatry at Gifu, in central Japan. Soon after their arrival in mid-April, however, the speakers were told that the meeting had been cancelled because of threats made by "anti-psychiatrists". Instead, a smaller private meeting was arranged at a hotel in nearby Nagoya. But, twenty minutes after Dr Crow's talk began, news came that a group of 70 demonstrators were on the way to the new location; the talk was abandoned and the meeting hall evacuated.

Behind these strange events lies a 16-year feud within Tokyo University's hospital and accusations of serious abuses within Japan's psychiatric hospitals. These accusations resulted in an inspection visit earlier this month from Disabled People's International (DPI), based in Stockholm and, two weeks ago, from the International Commission of Jurists (ICJ) and the International Commission of Health Professionals (ICHP), both based in Geneva.

The Gifu meeting had itself attracted attention from anti-psychiatrists because lurid publicity had just been given to the ethics of research performed at Gifu University. In February 1984, a schizophrenic woman patient admitted to a local hospital had received an abortion; the fetus's brain had then been examined in the university to look at the effects of drugs the patient had been taking. Accusations followed this year, however, that the patient had wanted to have a child and that she had been forced into the abortion in order to provide research material for a "human experiment". Although the matter was taken up by the Diet, investigations have not so far revealed malpractice.

The "anti-psychiatrists", however, see this experiment as just one more example of the "research supremism" they claim permeates the psychiatric community and which regards psychiatrically-ill patients as being without rights, mere fodder to further scientific careers.

This view has been propagated by a radical group of doctors who, in a truly bizarre episode, established themselves within Tokyo University's hospital in the wake of the student revolt in the 1960s. At the end of the troubles, in 1969, some radical doctors, opposed to the current form of psychiatric education and treatment, seized the in-patient psychiatric ward and used violence to prevent those who did not support them from entering the ward. Since then most of the university's neuropsychiatrists have not been able to enter the building or see the remaining patients.

An attempt was made to solve the problem in 1972. Relatives of confined patients were asked to consider moving them elsewhere; some, but not all, did so. Eventually, as doctors and nurses left, and radical doctors from elsewhere began to work in the ward, the point was reached when there were no officially-authorized staff left. The university, however, continued to supply drugs, food and equipment and to avoid confrontation on the grounds that that would not be in the interest of the remaining patients.

This strange situation persisted until 1978, when the Diet appointed an investigatory committee. The committee put pressure on the university to solve the problem without suggesting how it might be done.

The university eventually chose to avoid a fight and to legitimize the occupiers' position. University posts were given to the radical doctors, the professor was in turn allowed to make a once-a-week token visit to the ward, and a single patient was sent there from the out-patient department.

Relations between the "orthodox doctors" in the out-patient department and the "radical" doctors in the in-patient ward have not however, improved. Out-patient doctors complain of frequent abuse and physical assaults from radicals who enter the out-patient ward, often even in front of patients undergoing treatment. No evidence of unethical conduct by members of the out-patient group has been presented to justify these assaults; instead it seems as though they are being made to answer for abuses that have occurred elsewhere — the very abuses that have led to appeals to the United Nations and visits from human rights groups.

The most notorious incident occurred last year at the Utsunomiya hospital where it was alleged that patients were regularly beaten, two of them to death, one for trying to escape and one for complaining about the food, and that unqualified staff and some patients were forced to act as nurses. The director was eventually arrested, although the case has never been completely cleared up.

The official government view, echoed by many psychiatrists, is that the Utsunomiya case is a rare exception. One person who believes otherwise is lawyer Etsuro Totsuka, who for the past few years has been working almost without pay investigating psychiatric abuses. He stresses that there is an abnormally large number of psychiatric patients in Japan (more than 300,000), many of them hospitalized for exceptionally long periods and most of them confined against their will (more than 80 per cent, against only 5 per cent in the United Kingdom). Hospitals, the great majority of them private and generating large profits, are usually built in remote areas where land is cheap but rehabilitation of patients through integration back into the community almost impossible.

Two main factors seem to lie behind these trends. First, Japan's Mental Health Law Article 33 allows a hospital administrator to commit people without their consent so long as parents or guardians agree; expert opinion from doctors is not required. Thus, as an editorial in the *Asahi* newspaper put it, there need be no surprise at the abnormally large number of people in mental hospitals because "decisions on whether or not to put the mentally ill in hospital are made, in many cases, by the hospital managers, who stand to profit from hospitalization".

The second factor is the considerable stigma still attached to the mentally ill. All too often, families with mentally-ill kin seem to want to dump them where they cannot be seen. Complaints of ill-treatment are thus likely to be few as people prefer not to be identified as having a mental patient in the family.

Detailed reports are not yet available from the three groups that made visits to Japan following lawyer Totsuka's appeal to the United Nations through the Fund for Mental Health and Human Rights that he helped set up. But James Donald of DPI has made an interim statement that "there appears to be no requirement that the decision to commit be made by a qualified expert there is no requirement for independent review of the decision no effective independent counsel is provided to the patient; and there appears to be no access to information on care and treatment of patients once they are put inside and consequently no protection from abuse". Lack of appropriate laws and regulations, and the absence of government supervision, lack of financial incentives to medical professionals for treatment in the community, and lack of general recognition of these rights by the larger community are all blamed for the current state of affairs.

In the eyes of foreign experts, legal reform is thus clearly indicated. Within Japan, however, the issue has so far excited little interest, except among those whose views have already become extreme. What is particularly lacking is a broad-based reform group, like MIND in the United Kingdom, even though there is a movement towards community care among psychiatrists. Even if the true scope of psychiatric abuse can be assessed and, if abuse exists, legal reforms made to remedy it, it is hard to see psychiatrists and "anti-psychiatrists" being reconciled.

Alun Anderson

Poland

University advances checked

THE Polish government's plans to reform the 1982 Higher Education Act will go ahead, in spite of strong opposition from the academic community. Last week, Warsaw University held a massive protest meeting and launched a last-minute appeal to the Sejm (Parliament) against the changes. Nevertheless, it now seems obvious that the government and party authorities were determined from the beginning to press ahead with the amendments, and the public discussion, launched at the end of December, was merely a placebo to the university community.

The amendments, which would annul the autonomy won during the Solidarity era and would give the Ministry of Science and Higher Education virtually unlimited disciplinary powers over the universities, have been strongly opposed not only by the academic community, but also by the government-sponsored "Patriotic Movement for National Rebirth" (PRON), launched during the martial law period in order (it was hoped) to attract the support of the masses to the ruling junta (WRON — the similarity of the acronyms was hardly coincidental) PRON in fact has not picked up the expected mass support, although it has consistently tried to woo the academic community, backing, for example, a proposal to convert the Bialystok "filial" of Warsaw University into an independent university by 1991.

Originally, it appears, the state and party authorities had hoped to amend the law without public outcry. Unfortunately, in October 1984, a confidential draft of the proposed changes was leaked to the underground press. Although Dr Benon Miskiewicz, the Minister of Science and Higher Education, denounced the alleged leak as a "provocation", he shortly afterwards laid his own proposals for change before the Main Council for Higher Education (a kind of parliament of the universities, with one elected delegate from every higher educational institution in Poland, except the Catholic University of Lublin which elected to remain aloof when the Main Council was constituted in 1981). Although 60 per cent of the delegates to the council are party members, they strongly opposed the changes, on the grounds that to revise the law so soon after enactment would tend to "destabilize" the universities. Largely as a result of the main council's opposition, a "public debate" on the amendments was launched at the end of the year by the Committee for Social and Political Affairs, which reports directly to the cabinet.

Articles appeared in the press from leading academics condemning the amendments, and virtually the only organization that favoured them was the party-approved Association of Polish Students (ZSP), which under the proposed changes would become the only representative organization of Polish students. (At present, ZSP has very little active support). Referenda organized among university staff and students produced almost embarrassingly high votes against the changes. Nevertheless, the usefulness of such referenda and articles was questioned by a document signed by the underground Solidarity leadership of Warsaw's eight universities and higher colleges, which, by the end of February, could be found lying about in classrooms and libraries. This claimed that the alleged public discussion was merely a means of allaying public concern, while the authorities pressed ahead with the changes.

At about the same time, a ministry spokesman admitted that the issue was simply whether or not the universities "belonged to the state", and that if they did, the changes must, willy-nilly, go through. (My tape-recording of this interview was subsequently confiscated by the Polish customs (see *Nature* 14 March, 1985, p.120).) After the referenda ended in mid-March there were several weeks of seeming impasse. Then, on 13 May, during a special plenary meeting of the Central Committee of the Polish United Workers' Party on the role of the intelligentsia, Politburo member Jozef Czyrek stated explicitly that the universities were indeed "state owned and socialist" and that therefore the changes must go through, to ensure that "anti-socialist groups" did not exploit university autonomy for their own ends.

A week later, on 21 May, the government press spokesman, Mr Jerzy Urban, announced that there would be no further consultations with the public and that although he could give no date, the amendments would soon be laid before the Sejm. Warsaw University's 3,000-strong protest meeting the next day, which included an address by the former leader of the university's Solidarity chapter, Maciej Geller, and from which all outsiders were excluded by student "guards", made it clear that the university community will fight to preserve its hard-won autonomy.

Vera Rich

Synchrotron source

Italy drives a hard bargain

ITALIAN science minister Luigi Granelli is not at all happy with the Franco-German *fait accompli* that led, effectively, to the choice of Grenoble in south-east France as the site for the planned European Synchroton Radiation Facility (ESRF). Mr Granelli may have to accept the Grenoble site — Italy had proposed Trieste — but France and Germany may see little sign of his lira unless, in the accepted diplomatic tradition, Italy receives something in exchange. It now seems that he is not to be bought off with a promise that a European tritium-handling facility — needed for the time when the Joint European Torus, JET, or its successor, the Next European Torus, NET, need to use tritium to reach nuclear ignition — will be built at Ispra, north of Milan. It had been thought that this was the *quid pro quo* that would yield Italian aquiescence to, and money for the Grenoble site, but this is "not quite right", Mr Granelli said in London earlier this month.

At present there is deadlock in the European council of ministers, which meets next on 4 June, over ESRF, Granelli intimated, as "everyone is using their veto" to prevent France and Germany moving forward. Italy has proposed a site in Trieste, a region which the government is keen to develop in order to maintain its historical toehold at the top of the Adriatic, and offered more financial support than any other single country (including France or Germany). And still Italy must have something in Trieste to balance its support for Grenoble, Granelli insisted.

"There could be the large laboratory in Grenoble, and something different in Trieste", he said. "We should look at the wider context and consider making two or three laboratories." He was prepared to be flexible about what those laboratories would be. Denmark for example, which had offered a site at Risø for ESRF, would be happy with a laboratory for oceanography.

"The council should always consider a number of facilities at the same time, then the opposition doesn't become so stiff", said Granelli. The tritium handling facility could not go into the package with ESRF, however, because "from all points of view it is not an Italian request. It's a common interest for the European Community."

Granelli would like to see big machines for Europe discussed in a more flexible way in future "as long as the Commission of the European Communities is involved". There could be arrangements where two or three countries might agree on a facility but the Commission should also be made a partner, to allow other European states to participate in a smaller way through the Commission.

Professor Paolo Fasella, director-general for research at the Commission in Brussels, agrees that this would be a useful formula. "In a slow and practical way we're already investigating it", he said. The Commission had made initial approaches to national laboratories such as the Rutherford Appleton Laboratory and the Daresbury Laboratory in the United Kingdom and Frascati in Italy, for part-participation on behalf of the Commission's "stimulation programme". "We want to develop collaboration in a flexible way", said Fasella.

Robert Walgate

Ganges pollution

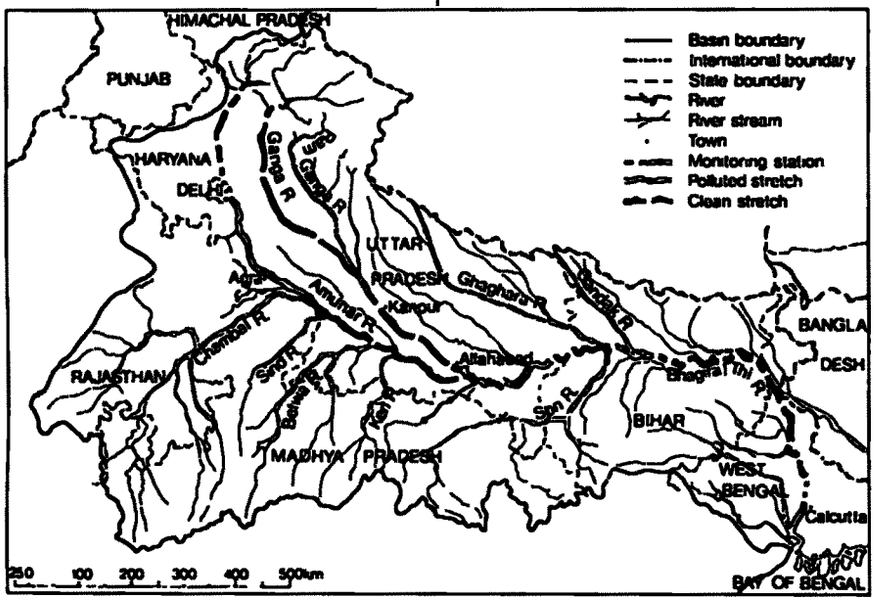
Cleansing river due for cleaning

New Delhi

INDIA'S holy river Ganges, which has been washing away the sins of devout Hindus for centuries, is itself to have a clean-up. The Indian government has set a five-year deadline for the first phase of cleaning the 2,500-km river, at a cost of £180 million. The river carries 468,000 million cubic metres of water a year, a quarter of the country's surface water.

The task has been assigned to the newly formed Ganga Authority, headed by Prime Minister Rajiv Gandhi himself. The eight other members include planning and environment ministers of the central government and chief ministers of three of the eight states through which the Ganges flows. There is also a 17-member steering committee under the chairmanship of environment secretary Dr T.N. Koshoo.

Pollution of the Ganges starts at Hardwar, where it enters the plains of Uttar Pradesh, 350 km from its source in Gangotri in the Himalayas. From Hardwar to Calcutta, the whole of the river has been declared by the Central Pollution Control Board (CPCB) as unfit even for bathing, and unsuitable for drinking without massive treatment. The board says the water has become so saline and so contaminated with toxic heavy metals that some parts of the Ganges basin are now infertile and the groundwater is polluted.



The Ganga Authority aims to restore the water quality under a plan drawn up by CPCB. Dr Nilay Choudhuri, CPCB's chairman, says that 80 per cent of the pollution is caused by raw sewage discharged directly into the river from 100 cities on its banks. The rest is caused by untreated effluent, wallowing and bathing of cattle, pesticide and fertilizer run-off and incompletely cremated dead bodies.

Apart from Hardwar, the most polluted places are Benaras, Kannauj, Allahabad, Patna, Calcutta and Kanpur, where the Ganges water is thick and turbid for 10 km because of effluent from tanneries, textile mills and chemical plants. Monkeys in Benaras have become addicted to opium in wastes discharged from a nearby factory making morphine from opium. On two occasions, the Ganges has caught fire because of oily effluent from a refinery in Barauni and discharges from a foundry forge plant in Hardwar.

Stopping the discharge of sewage into the river will reduce pollution of the Ganges by 75 per cent according to Dr Koshoo. Twenty-seven cities with populations of more than 100,000 dump 900 million litres of municipal waste each day. The plan is to renovate existing sewerage systems and pumping stations and to build new drains to divert the wastes to what are called Resource Recycling Units (RRU), where sewage will be digested to produce methane gas that will generate electricity. The residue will be sold as manure. Liquid remnants will be cleansed by biological aerators and the water produced will be used for irrigation and for growing algae and fish for sale.

According to Choudhuri, each RRU serving a population of 100,000 is expected to make an annual profit of £850,000, a sufficient incentive for private companies to take over the operation of the units after they have been built with government funds. In the second phase, the plan will be extended to the remaining 63 cities, and community cattle-sheds will be set up to collect animal wastes for processing at RRUs.

Unlike the Thames or the Danube, the cleaning up of the river Ganges is complicated by the fact that it is a sacred river to the Hindus. Millions of pilgrims immerse themselves in the river during festivals such as the Kumbha Mela and return home with a vessel filled with Ganges water.

Choudhuri says that a mobile laboratory found 10,500 coliform counts in 100-ml samples taking during a Kumba Mela in Allahabad. In Hardwar, 17.5 million litres of human and industrial waste pour daily from five drains, one of which is just upstream from where 10,000 people bathe every day and a million bathe during the Kumba Mela. At Benaras, 70,000 bathe daily in water that has been turned into an open sewer with the outfall of 120 million litres a day of sewage from 66 drains. Cremation in Benaras is the wish of every Hindu, so 400 half-burnt bodies float in the river on any day, and 9,000 cattle are thrown in each year. It is intended that electric crematoria will be built at several places along the river bank.

Even more alarming is the fact that the alluvial soil in the Ganges basin is showing signs of salinity in the state of Haryana, alkalinity in western Uttar Pradesh, acidity in West Bengal and calcareousness in north Bihar. Irrigation of Ganges water adds 17 million tonnes of salt a year to the soil, according to CPCB. The Ganges basin receives 3,000 tonnes of pesticides a year and one-third of all the fertilizer used in India.

K.S. Jayaraman

Polio eradication

Washington

A PLAN to eradicate poliomyelitis from the Americas by the year 1990 has been announced by the Pan-American Health Organization (PAHO). PAHO believes the goal can be achieved by using its staff and volunteers to coordinate separate national efforts to encourage immunization.

The total cost of eradicating polio from North and South America is estimated at $100 million: much of the infrastructure required is, however, already in place and only about $30 million will be needed in aid from developed countries, much of which is already committed. Since 1977, when the World Health Organization instituted an expanded immunization programme to fight several common infectious diseases, the incidence of polio in the Americas has fallen from around 2,300 cases a year to 489 cases in 1984.

Dr Carlyle Guerra de Macedo, director of PAHO, says that 75 per cent of those under one year old in the Americas are now immunized against polio; before the expanded programme started, the figure was 25 per cent. The new plan will concentrate on surveillance and on training health workers to implement vaccination schemes. While admitting that the goal will not be easily achieved, Guerra de Macedo pointed out that the Americas were the first region of the World Health Organization to succeed in eliminating smallpox. The polio virus, like the smallpox virus, cannot survive for long periods outside a host and there is no animal reservoir. Total world elimination of polio is therefore a realistic goal.

Tim Beardsley

Running down observatories

SIR — As a university astronomer who has had much to do with both the Science and Engineering Council (SERC) observatories at all levels, including serving on committees charged with looking into whether they could best be merged with each other, or elsewhere, I would like to comment on your leading article on "Running telescopes" (*Nature* 9 May, p.86) which is a mine of misinformation.

Before there is any talk of closing or merging anything, with all the personal and professional upset and delay that will certainly entail, the case has to be made, and indisputably made, that there are significant inefficiencies in the present system of two observatories at Herstmonceux and Edinburgh, sharing some of their tasks, computing for example, with the Rutherford Appleton Laboratory. To that extent I agree with *Nature* that the widest terms of reference must be given to the new committee, if there has to be one so shortly after the last, which I doubt, looking into the best way of running our overseas telescopes.

Building and operating a high technology instrument on an exceedingly remote and sometimes physically hostile foreign site, transporting shifts of UK university astronomers there, looking after them, educating them in the intricacies of the local equipment, which has to be maintained at the highest efficiency, providing them with the technical help to get first rate data, and later the sophisticated computer network required to reduce such data, must be a technical and management challenge of the same order as running an aircraft carrier full of Harriers at war in the Falklands. Mistakes are inevitable, and any number of committees can be set up to look into how the task can be better done, and of course the less they know about the practicalities the easier it will be for them to recommend sweeping changes.

The professional and the user, however, will only be convinced by a proper comparison, carried out largely by observationalists, of the existing UK set-up with its competent counterparts abroad such as the Cerro Tololo Inter-American Observatory (US) and the European Southern Observatory based in Munich. My own survey, for what it was worth, showed the UK observatories in a very favourable light. If the new committee fails to make a similar but much more careful comparison, co-opting the advice of astronomers abroad, and taking the time to do it properly, they will certainly have failed astronomers, like myself, out in the UK universities. At present we are lucky enough to have access to shared facilities which are remarkable not for their size, as your leading article implies, but for their sheer quality, something in which both observatories, and the Rutherford Appleton Laboratory, can take a just pride. Such quality arises not from lavish expenditure but from vision, high skill and dedication, as well as the very closest cooperation with the user community.

All this could be easily lost in the sort of reorganization or tidying up so beloved by (and alas in the United Kingdom indulged in by) second-rate administrators on their way up the civil service career ladder. One would have thought the amalgamations that led to British Leyland would have taught somebody up there a lesson.

The predictions are that the United States will be running short of astronomers in 2-3 years time. The demoralization that is now spreading through our UK observatories as a result of continual misinformed sniping by those who do not use them, and a never-ending series of superficial reviews, can in the end have only one result. And when the best SERC people have left on the plane, the rest of us, contemplating the resulting inevitable decline in the competitiveness of our own far from ambitious facilities (our colleagues abroad are going up to 10 or 15 metre class telescopes), will be studying the job columns too. To their credit, our observatories have played a major part recently in catapulting British optical and infrared astronomy from mediocrity into the front rank. In a society increasingly settling for the seedy and the second-rate perhaps that is their crime.

Philistinism?

SIR — If the idea of exploring more unorthodox ways of funding science than using the increasingly tired arguments for an ever-increasing Science Vote is the role of a scientific philistine then I must accept that label. What a pity though that a once great industrial society should display cultural antipathy to modern commerce of the sort revealed in your leading article (25 April, p.657).

My purpose in trying to provoke a debate on these important issues (not incidentally the unwitting act on my part that you seem to think) is to get scientists to consider a little more, in these financially difficult times, their role in society and their justification for that role being supported from the country's tax base. How you can contend that it is valid to challenge the scientific community with such arguments but not ask individual scientists to accept their implications is beyond me.

Of course I realize that not all science is commercially exploitable. Much of my own research on viruses has been in that category. But I still claim that there is a need for scientists to think purposefully about whether commercial opportunity exists and how it can be harnessed. Though there are some of us who need no such urging, this is not an area in which we have demonstrated much skill in the past. We might all benefit if more of us thought it important and generated income for ourselves, our institutions and our country as a result.

A major point in my *Times* letter that you did not choose even to misquote was that such a strategy could well generate funds for basic science both directly and from government. It is surely worth giving our thinking a nudge in this direction, to counterbalance the traditional arguments so frequently put, even at the risk of incurring the wrath of the Editor of *Nature*

Imunovir

SIR — Helen Wright's reply[1] fails to destroy Dimitri Viza's complaint[2] that the drug isoprinosine was hyped by excessive promotion, but rather confirms his implicit contention that the publicity for a product is proportional to the doubts about its activity. This contrasts with the case of an effective treatment for herpes; there has been no excessive publicity in the promotions of acyclovir, a drug whose virtues and limitations are well documented.

All but one of the references cited by Wright to prove the efficacy of Imunovir are to communications at meetings between 1973 and 1981, suggesting that none was followed up by a formal paper. She omits references to work suggesting the absence of effect[3,4].

There is a striking difference between Wright's arguments in defence of Imunovir — a 60 per cent cure of herpes bouts within a week, the praise of Prix Galien's jury for a drug arousing "new hopes for the treatment of infectious diseases, auto-immune diseases, allergy and — why not? — cancer" and the absence as yet of any convincing clinical trial. This is even more baffling if one considers that isoprinosine has been tested for more than 12 years.

I cannot therefore but agree that pharmaceutical companies would be well advised to avoid raising excessive hopes through lay media or otherwise. Since mediaeval times, people have been wary of panaceas. This is only one of the reasons why I am prepared to wager that in another five years isoprinosine will have fallen into oblivion. But Viza's proposal that there should be more scrutiny and responsibility in lay publications deserves to succeed.

Circle No. 69 on Reader Service Card

What are we doing in the centre of Liverpool?

Imagine the ideal environment for high-tech businesses. A place designed for technologies of the future with scientific skills, research facilities and business expertise.

That's what we've been doing in Liverpool. Creating this environment in the new Wavertree Technology Park and moving Liverpool forward into a new era.

Move into your exclusive factory

To maintain a unique working environment Wavertree is reserved exclusively for high technology companies. It covers 64 acres of landscaped park and rents start at £35 per week. Modern offices and factories are ready for occupation and if you want to construct your own premises, sites are available up to 10 acres.

Maximum Aid

Moving to Wavertree enables you to take advantage of maximum grants. Qualifying companies are eligible for the top Regional Development Grants towards staffing and expenditure on fixed assets. This makes Wavertree a healthy financial proposition.

High technology people and resources

To keep ahead, high-tech businesses need a constant flow of new ideas. This means having the right people and the right back up. In Wavertree you have both with the scientific skills and research facilities of Liverpool's University and Polytechnic.

Road, rail, air and sea connections

Wavertree is one mile from the M62 linking you to the national motorway network. Inter-city rail links and national and international air services give fast connections and Liverpool's Freeport trades worldwide.

A total business package

In Wavertree, we've provided powerful back-up facilities. On-site secretarial and office services, a bank, restaurant, health centre and conference suites. We'll advise on planning permission, construction and grants so that your move goes ahead smoothly and swiftly.

If you've wondered what we were doing in the centre of Liverpool ask yourself what you could be doing in Wavertree. Then ring Stanton Fuller on 051-228 2722.

Piecemeal ballistic missile defence

The US programme of research known as the Strategic Defense Initiative will come to fruition only in the next century (if then), but there may be tangible and awkward results much sooner.

EVER since President Reagan's announcement in March 1983 of the plan for a programme of research on ballistic missile defence, there has been a temptation to assume that the whole programme would come to fruition (or not) all at once. Then, we have assumed, it would fall to a Pentagon committee to recommend (or otherwise) the deployment of an integrated system of anti-missile defence. And then it would be for politicians to take up the question which they have promised must be explored before such a defensive system could be put in place, negotiations with the Soviet Union not least among them. Only then, the argument has gone, would it be decided what should be done with the products of many years of research.

A little thought will show that events cannot follow such a simple course. The objective of the system now being talked about in Washington, in its most flamboyant form, is first to detect hostile ballistic missiles early in their trajectory and then to destroy them by means of several layers of defence. If boost-phase missiles escape attack, there would ideally be means of destroying the components into which they separate, first "buses" containing several warheads and, later, individual reentry vehicles. Much of the argument of those working on the programme rests on the calculation that the most effective route to a missile defence will be an efficient way of destroying missiles while their booster motors are still burning, and are thus conspicuous targets for the detector satellites equipped with infrared sensors.

To say the least, each successful strike against a hostile missile in this boost stage would get rid of a great many warheads. But it is also generally agreed that the detection problem is also then much easier than during the intermediate stages (when decoys will be an obvious stratagem for the missile launchers to use). Indeed, detection becomes relatively simple again only towards the end of a trajectory, when warheads declare themselves by the heat they generate.

No secret knowledge is required to make reasonable guesses about the sequence in which the various components of this system will become available to the military. The technology for detecting missiles during the boost phase probably requires nothing radically new. Infrared detectors have indeed been used to spot rocket boosters rising through the atmosphere. There is no reason why detection should not be reasonably efficient at heights above the ground not very different from those at which people operate infrared telescopes, a few kilometres or so.

The practical task will be to incorporate an array of such detectors into a system of satellites and then handle the data that accumulate. Discrimination between real and imagined targets will obviously be a headache. Software designers will be fully stretched. But the first practical by-product of the research programme will be an early warning system of such sophistication that it might have been considered desirable in its own right.

The other almost certain outcome of the research programme is a better system of terminal defence than that planned by the United States in the late 1960s. The idea then was that a fast take-off missile (called "Sprint") would fire nuclear warheads at incoming warheads; now, it seems, people are persuaded that it would be better to send guided mechanical devices at incoming warheads, in the hope that they might be destroyed without killing the people whose defence is the object of the whole exercise.

So the research programme will almost certainly yield two military options for the United States — a much better (in the sense of much earlier) early warning system and a workable system of terminal defence. Whether the research programme will contribute anything else is still an open question.

The important article in last week's *Nature* (23 May, p.286) by Dr Richard Garwin is a generalized expression of the kind of scepticism with which the research programme will have to contend. Any system of satellites intended to be the bases ("battle stations" is the fashionable term) for the means by which targets will be destroyed will have to be much more elaborate than the enthusiasts have been saying. Even quite optimistic assumptions about the efficacy of lasers as means of shooting down hostile missiles imply much larger numbers of battle stations than people have been saying.

The need for a host of satellite battle stations is generally accepted. Because these machines, whatever their armoury (lasers, neutral-beam projectors or rail guns), will have to be in comparatively low orbits to get within striking distance (say 1,000 km) of a booster rising through the atmosphere, the chances are that any single one of them will be the wrong side of the Earth when needed. But the ballistic missile defence community has sought some comfort in the widely shared belief that the number of satellites required will be proportional only to the square root of the number of potential targets. Garwin disproves that cheerful assumption.

This is the technical nightmare of the whole project. Even though the mass-production cost of making, say, 1,000 battle stations will yield economies of scale, the efficient management of such a system would be a task of quite unprecedented character. Only a means of destroying boosters at much greater range than 1,000 km would bring drastic simplification. Because none of the potential guns has yet emerged as a possible leader, let alone been demonstrated, it seems a fair guess that this part of the programme will be much delayed. No Pentagon committee is going to be making a recommendation to deploy the system this side of the end of the decade. Whether that time will come this century is far from certain.

The consequences of this piecemeal fruition of the various components of the programme are themselves important. If, as seems likely, one early outcome is a feasible system of terminal defence, it seems likely that the United States will follow the Soviet Union in deploying such a system somewhere, presumably in the Minuteman missile fields where the MX missile is now to be deployed. (The Anti-Ballistic Missile Treaty originally offered each side the option of two such systems, later reduced to one.) An orbiting early-warning system, the other likely early product of the research programme, will be diplomatically more perplexing. Quite apart from the formidable technical difficulties of launching, operating and maintaining such a system, there seems very little doubt that it would violate the spirit if not the letter of the treaty.

The result is that, while the Strategic Defense Initiative will not yield tangible results for a decade or more ("if then", as the critics would add), there is every likelihood that some essential parts of the system will be ready for use long before that. So the United States may quite soon find itself having to keep to the promise extracted from the administration by Mrs Margaret Thatcher last December that deployment would depend on talks with the Soviet Union. Raising the questions now, at the arms control talks at Geneva, would be prudent.

John Maddox

Plant genetics

A plant joins the pantheon at last?

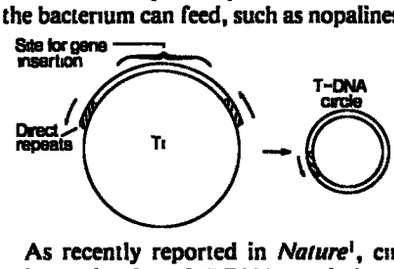
from Geoffrey North

As Keith Roberts has recently remarked in *Nature*[1], plants should be wonderful systems for the study of development. Why, then, has progress in understanding cell differentiation and morphogenesis in plants been so slow? One reason, surely, has been the lack of a plant equivalent of the fruitfly *Drosophila melanogaster*: a rapidly breeding species that is easy to keep in large numbers in the laboratory, and is ideal for intensive study by the combination of molecular and genetic techniques that has proved so successful in dissecting the regulation of development in *Drosophila*[2]. But it seems plant scientists need look no further, for the indications from a recent meeting* are that the small weed *Arabidopsis thaliana* (the common wall cress; see sketch) could prove to be just the right subject. And the hope that molecular biology will transform practical plant breeding must have been boosted by reports at the same meeting of the correctly regulated expression of exogenous genes introduced into plants using the natural vector system provided by the bacterium *Agrobacterium tumefaciens*.

Although the science of genetics began with Mendel's experiments with peas, on the whole plants are far from ideal subjects for molecular geneticists. They usually require a lot of space and special conditions for their upkeep, and, worse, as a rule undergo only one or at most a few breeding cycles in a year. Furthermore, the species on which plant geneticists have concentrated most of their efforts, such as maize, tend to have enormous genomes — in the region of two orders of magnitude larger than those of *Drosophila* or yeast, which is a considerable handicap if your aim is to isolate a specific gene. These considerations led Elliot Meyerowitz (California Institute of Technology) to the temperate weed *Arabidopsis thaliana*, a member of the Cruciferae (mustards) Although the first *Arabidopsis* mutations were reported in the 1940s and it has since been used extensively in the genetic analysis of plant biochemistry (C. Sommerville, Michigan State University; see ref 3 for a recent genetic map of *Arabidopsis*), its potential as a subject for intensive molecular genetic analysis seems hitherto to have largely been unexploited.

The features that attracted Meyerowitz to *Arabidopsis* are the ease with which it can be grown in the laboratory, its small size and extraordinarily short generation time (only 4-5 weeks), and its unusually small genome[4] On the basis of DNA reassociation kinetics Meyerowitz estimates that the *Arabidopsis* genome is only ~70,000 kilobases (kb)[5], the smallest yet for any plant and comparable to the yeast, nematode and *Drosophila* genomes. For comparison, the size of the human genome is ~2,000,000 kb, and that of rye is ~7,900,000 kb Furthermore, the DNA reassociation kinetics show that the *Arabidopsis* genome is remarkably low in repetitive sequences, which should facilitate the application of the 'chromosome-walking' technique for isolating genes that made possible the cloning of the bithorax complex of *Drosophila*. Meyerowitz hopes that the small genome of *Arabidopsis* will rapidly be covered with sites of restriction-fragment length polymorphisms — his group have already detected a few by simply using randomly selected clones from an *Arabidopsis* genome library. These can be used to map new mutations and as starting points of chromosome-walks to clone the sites of the mutations

The economy of the *Arabidopsis* genome is also reflected at the level of specific genes; for example, where most plants have multiple copies of the genes for seed proteins, *Arabidopsis* has, according to Meyerowitz, only one. And using their cloned *Arabidopsis* seed protein gene as a probe, Meyerowitz's group have carried out the first analysis of gene expression in plants by hybridization *in situ*. In sections of seeds, they can detect seed protein messenger RNA only in embryo cells, which are known to be the sites of seed protein synthesis in *Arabidopsis*. The result in itself is to be expected; what is important is that it shows the powerful technique of hybridization *in situ* can be applied in *Arabidopsis*. It is not always easy to make it work and this has, for example, been the principal barrier to progress in research on homoeotic gene expression in vertebrates.

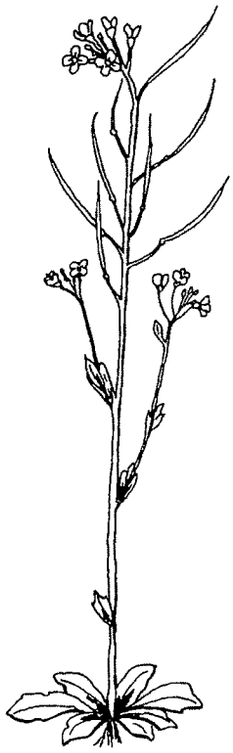


Arabidopsis seems to be as amenable to the techniques of cell culture, plant regeneration and *Agrobacterium tumefaciens*-mediated transformation[6] as plants such as tobacco (see below and box). One of the problems that has frustrated plant scientists in recent years has been the lack of any one species that is both amenable to such techniques and has been well-studied genetically. And although I. Potrykus (Friedrich-Miescher Institute) and E. Howard (CSIRO) both reported that they have been able directly to introduce DNA into protoplasts of monocotyledenous plants, the difficulties in regenerating such plants from cells in culture make it likely that *Arabidopsis* will be the first genetically well-defined plant into which exogenous genes can be introduced readily.

The most exciting prospect offered by *Arabidopsis* is in its potential for the identification, genetic mapping and cloning of those genes which, on the basis of the effects of their mutations, seem likely to be very closely involved in the regulation of

*The 1985 UCLA symposium on plant genetics was held at Keystone, Colorado, USA from April 13 19 1985

Plant transformation



To date, the success of plant geneticists in introducing new genes into plants has depended on the exploitation of a remarkable natural system of interspecific gene transfer. The bacterium *Agrobacterium tumefaciens* can induce the formation of tumours on many plant species. This is known to involve the transfer of a fragment of DNA (the T-DNA), carried on the bacterium's tumour-inducing (Ti) plasmid, to the genome of the infected plant cell. It is the genes carried by the T-DNA that cause the transformed cells to divide to form tumours and that pervert the metabolism of the tumour cells so that they make products on which the bacterium can feed, such as nopalines

As recently reported in *Nature*[1], circular molecules of T-DNA are induced within the bacterial cells in response to some plant-derived signal. It is presumed that these molecules repesent intermediates in the process of gene transfer — though as yet no T-DNA circles have been detected in plant cells. The junction of the T-DNA circles occurs at a precise point within the short (25 base pair) direct repeats that flank the T-DNA on the Ti plasmid, and simply by inserting a piece of DNA between these repeats it can be transferred to the genome of a plant cell. So that whole plants can be regenerated from the transformed cells, 'oncogenic' genes of the T-DNA are usually removed and replaced by a selectable marker, such as an antibiotic-resistance gene.

Unfortunately, it has so far not been possible to use this system to transform monocotyledenous plants, despite the indications that they can be infected by *Agrobacterium tumefaciens*[2,3]. One alternative approach that is being pursued at present is to see whether transposable elements could be used to introduce genes into plants, much as P-elements are used to transform *Drosophila*. As a start in this direction, R.B. Simpson (ARCO, Dublin, California) reported at the plant genetics symposium that his group has begun to explore the potential of the maize *Mu* (Robertson's *mutator*) transposable elements as vehicles for transforming monocots **Geoffrey North**

ARABIDOPSIS THALIANA

Redrawn from *The New Concise British Flora* by W. Keble Martin (Ebury Press and Michael Joseph, London, 1982)

development. Several such mutations were described in Colorado, for example, by D. Meinke (Oklahoma State University), who explained that he and his colleagues have identified a number of embryonic-lethal mutations that cause arrest at different stages of development by exposing *Arabidopsis* plants to the mutagen EMS and then screening the seed pods for aborted seeds. Meyerowitz's group have reanalysed a mutation termed *apetala-1*, classically described as causing a failure of petal development; they find that occasionally petals are replaced by entire new buds.

The *apetala-1* mutation is somewhat reminiscent of the homeotic mutations of *Drosophila*, in which one body part may be transformed into another. Perhaps more closely comparable, at least at the phenotypic level, are the maize mutations *Corngrass* and *Teopod 1* and *2*, described by S. Poethig (University of Pennsylvania). The repetitive structure of a maize shoot, with units (termed phytomers) comprising a leaf, a node and a portion of stem, is at least superficially similar to segmentation in animals, the pattern of which can be affected by homoeotic mutations. In maize, at fairly precise positions up the plant, the character of the phytomers changes: from vegetative at the bottom through female flower (ear)-forming to male flower (tassel)-forming at the top. The effects of *Corngrass* and *Teopod* mutations can be interpreted as transforming upper phytomers into lower phytomers, as shown by leaf-shape and the replacement of flower parts by vegetative structures.

Another maize gene worth mentioning in this context is the *R*-locus, which is not only intriguing in its own right but illustrates another strategy for the cloning of plant genes. The interest in the *R*-locus lies in the observation that mutations in different regions of the locus specifically affect the coloration of different parts of the plant so, as J. Kermicle (University of Wisconsin) explained, it seems likely that the *R*-locus is somehow involved in regulating the tissue-specific pattern of expression of the enzymes of anthocyanin synthesis in maize. S. Dellaporta (Cold Spring Harbor Laboratory) reported that the insertion of a transposable *Ac* (*Activator*) element into the *R*-locus of mutant maize has allowed the cloning of the locus — the *Ac* element had already been cloned, so could be used as a stepping-stone to clone the adjacent *R* DNA.

If the *R*-locus really is a 'master' regulatory gene, then its most likely targets would be DNA sequences that determine the pattern of expression of the genes for the enzymes of anthocyanin synthesis. The technique of introducing defined fragments of exogenous DNA into plants by *Agrobacterium tumefaciens*-mediated transformation, alluded to briefly above, offers a direct route to the identification of such sequences, and the power of the approach was well illustrated at the meeting. R. Goldberg (UCLA) reported that when fragments of DNA including either the trypsin inhibitor or seed lectin genes of soya bean are introduced into tobacco cells and whole plants are regenerated from the transformed cells, the exogenous genes are developmentally regulated just as they are in soya-bean plants. RNA transcripts can be detected in developing embryos at the correct times during embryogenesis, and in other tissues either no transcripts or the same low levels that occur in the equivalent tissues of soya bean are found. And when a large fragment of soya-bean genomic DNA, containing the seed-lectin gene and several neighbouring genes with different development profiles of expression, is incorporated into tobacco plants each gene is differentially regulated in the transformed plants in precisely the same way as in the soya bean. Similarly, Sengupta-Gopalan *et al.*[7] have found that when the gene for the major seed storage glycoprotein (β-phaseolin) of French bean is introduced into tobacco plants, on a fragment of DNA that includes the β-phaseolin coding-region with about a kilobase of 5′ flanking sequence, it retains its normal pattern of expression: β-phaseolin can first be detected in the seeds of the transformed plants at the time it normally would appear in developing French bean seeds, several days after the tobacco plants' own storage proteins have started to accumulate.

The implication of these results is that the fragments of soya-bean and French-bean genomes introduced into the tobacco plants include the information to specify in which tissue the genes should be expressed. The definition of the sequences that comprise this information should be relatively straightforward; but to know how to direct the expression of any gene to seed-tissue should be an exciting prospect for those who wish to use molecular genetic techniques to improve crop plants. □

Planetary science

More news from Mars

from I.P. Wright and M M. Grady

SAMPLES of Mars have been delivered to the Earth as meteorites, but this has been appreciated only in the past few years, following, among other things, the discovery of meteorites from Antartica that have a demonstrable lunar origin. The stimulus this has provided for the discipline of Solar System geochemistry was clearly evident at a recent conference on lunar and planetary science*. Four shergottites (S), three nakhlites (N) and one chassignite (C) together make up the eight so-called SNC meteorites thought to originate from Mars. Detailed studies of these, and in particular the results of a consortium investigation of the Shergotty meteorite (organized by J.C. Laul, Battelle Pacific North West Laboratory, Washington), have thrown new light on martian history as well as the processes by which the SNC meteorites themselves were delivered to Earth. The SNC meteorites provide a bridge between laboratory-based analyses aimed at elucidating the origins and evolution of the Earth, Moon and meteorites, and planetary geology.

Research groups at the Battelle Pacific North West Laboratory, Max-Planck-Institut fur Chemie, Mainz and Purdue Universities (headed by J.C. Laul, H. Wanke and M.E. Lipschutz, respectively) have made detailed chemical analyses of the Shergotty meteorite, which provide constraints on the bulk composition of the parent body. Their deductions of the composition of the parent body comply with that inferred from geophysical data (density, moment-of-inertia factors, etc.) concerning the core/mantle structure of Mars. There are subtle variations in chemical composition that demonstrate that Shergotty is heterogeneous on a centimetre scale; for example, there are large variations in concentrations of volatile elements such as cadmium, tellurium, thallium and bismuth. The separated minerals contain widely differing proportions of rare-earth elements (REE), with phosphates such as apatite and whitlockite containing 500 times the proportions found in chondrites. In addition,

*The 16th lunar and planetary science conference was held in Houston, Texas, 11-15 March, 1985

the light REE seem to be concentrated in the iron-rich rims of clinopyroxene crystals. It is clear from the trace-element data that Shergotty and EETA 79001 (an Antarctic shergottite) are not related to the same parent magma. Further chemical studies show a high abundance of tungsten in Shergotty (which has a molybdenum/tungsten ratio of 1.0, compared with 5.9 for the terrestrial mantle); this seems to accord with various processes thought to operate during core formation and is consistent with the view that Mars was formed by homogeneous accretion.

Previous oxygen isotope measurements of whole-rock samples have demonstrated that SNC meteorites form a distinct group that probably originated on a single parent body distinct from the Earth-Moon system. The oxygen isotope composition of mineral separates of Shergotty has been determined by R.N. Clayton and T.K. Mayeda (University of Chicago). Data from mineral pairs give equilibration temperatures of 1,100 ± 100°C; the degree of isotope fractionation between the mineral pairs is lower than that often seen in equivalent terrestrial materials and demonstrates that little, if any, secondary exchange with water has taken place following crystallization. Not all the minerals analysed conform to this interpretation. Indeed, a maskelynite (shocked plagioclase) separate from Shergotty has an extremely anomalous oxygen isotope composition, although this cannot be due to the shock process itself because maskelynite from other shergottites shows no unusual isotope composition. The 0.4 per cent enrichment of ^{18}O in the maskelynite from Shergotty remains an intriguing and unexplained result, possibly reflecting low-temperature alteration.

Nitrogen in shocked glass from EETA 79001 has previously been shown to have an isotope composition enriched in ^{15}N, consistent with an origin from the martian atmosphere. A portion of the nitrogen in Shergotty also appears to be of atmospheric origin. Two groups, R.H. Becker and R.O. Pepin (University of Minnesota) and R.H. Carr, I.P. Wright and C.T. Pillinger (Open University), have found evidence for a nitrogen component in Shergotty that shows a 6 per cent enrichment of ^{15}N. It is thus considered that the shergottites probably contain microscopic and heterogeneously distributed shock-produced glasses that in turn contain samples of the martian atmosphere. J. Yang and S. Epstein (California Institute of Techology) and Carr *et al.* find that some of the carbon in Shergotty is enriched in ^{13}C, consistent with both isotope measurements of CO_2 in the shock-produced glass in EETA 79001 and by *in situ* measurements of the martian atmosphere by the Viking spacecraft. Thus, some of the CO_2 in Shergotty also seems to be of martian atmospheric origin, although the picture is somewhat confused by the presence of a number of indigenous carbon-bearing components that need to be further resolved before the carbon chemistry of the SNC meteorites is completely understood.

The glass fraction of EETA 79001 has been subjected to detailed optical examination by D.W. Muenow and J.L. Gooding (University of Hawaii; NASA Johnson Space Center, Houston). Using scanning electron microscopy, they have recently identified two distinct components in the glass fraction — a smooth glass and a 'ribbed' glass, which is thought to be quench-textured augite. Vesicles have also been identified in the glasses, as have sulphur-rich aluminosilicate crystals that are finely disseminated throughout the samples. It is possible that these secondary minerals are products of Antarctic weathering, although they may have originated on another volatile-rich planet, such as Mars.

J.H. Jones (University of Arizona) stirred up controversy by proposing that the previously accepted chronology of the shergottites should be called into question. Briefly, the current dogma is that the shergottites have an igneous origin at 1,300 Myr, then underwent impact metamorphism and subsequent ejection from the martian surface at 180 Myr. The new hypothesis, based on a reappraisal of existing trace element and isotope data, suggests that the shergottites were actually formed in an igneous event about 180 Myr ago. Furthermore, the cosmic-ray exposure age of shergottites (2.5 Myr), previously thought by most people to represent the time the meteorite fragmented in space, may actually approximate to the time the samples were ejected from Mars. The shorter exposure age of EETA 79001 would, however, require two separate ejection events for the shergottite meteorites, which poses problems as it demands high cratering rates on Mars over the past few million years.

The results obtained from studies of SNC meteorites have widespread implications for theories of Solar System formation, planetary accretion, thermal histories of planets and petrogenesis on planetary bodies. Chemical and isotope analyses of SNC meteorites have given a clearer appreciation of the composition of the martian surface and atmosphere. There is a strong feeling in the community of lunar and planetary investigators that a Mars sample-return mission should be given high priority in space exploration programmes in the years ahead. □

Developmental neurobiology

What guides growing axons?

from Dennis Summerbell and R. Victoria Stirling

DURING normal development, neurones form processes that grow long distances to connect with their targets. They produce a precise and repeatable pattern that is essential for normal functioning of the nervous system. There are numerous theories about the mechanisms involved in forming this pattern and three papers in this issue illustrate different ways of looking at the development of these connections, in tissue culture, in explants and *in vitro*. None of the papers present new explanations but all are important because they involve observing events as they happen, rather than at a fixed end point.

By removing nerve cells into tissue culture, one can control most carefully for critical single factors. We already know that axons prefer to grow along particular substrates, for example, laminin, but can one demonstrate thay they have specific preferences? On page 409, Bonhoeffer and Huf describe a Y-maze in which embryonic chick retinal axons from one edge of the eye are given the choice of growing along axons from the same position or axons from the opposite edge 180° away. Axons from one particular location (temporal retina) clearly prefer to grow along their neighbours, whereas axons from the opposite (nasal) side show no such preference. Here, in a dish, we can watch axons exhibiting the kind of behaviour suggested from static observations of their trajectories in fixed amphibian brains, in which temporal axons are found in a tight bundle in the optic tract while those from nasal retina, 180° away, are distributed across its entire width. The development of the highly ordered projection from the eye to the brain may depend on such differences, using them, for example, to set up the orientation of the map, and this kind of experiment has the potential for analysing the molecular basis for the differences.

But such fundamental yes/no decisions are only part of the story; a second approach is systematically to remove putative guidance cues and observe the resulting pattern of axon growth. The developing insect wing provides a culture system for the study of nerve growth that is less abstracted from the whole animal. The wing primordium starts life as a hollow flattened disk (the imaginal disk), rather like a pitta bread, in which the guidance of axons from peripheral sensory cells can be followed. Blair, Murray and Palka (on page 406) have adopted this model to look at the role of the substrate in axonal navigation. Axons from the sensory cells in the wing follow stereotyped pathways towards the central nervous system. Among the possible cues they might use are the channels between the dorsal and ventral surfaces of the wing, but when the disk is split into

separate dorsal and ventral halves, the dorsal axons are still able to find their way despite the absence of channels to guide them. Another possible cue is the nearby neurones, which in whole embryos appear to act as 'stepping stones' or 'guideposts'. Laser destruction of these guideposts leads to disoriented growth of specific axons (Raper, J.A., Bastiani, M.J. and Goodman, C.S. *J. Neurosci.* **4**, 2329; 1984). In the present experiments, the removal of the proximal guidepost neurone did not prevent the axons of more distal cells from moving initally in the right direction.

In both these experimental systems, molecular dissection could be contemplated, but one must remember that cells in culture are not in their natural environment. Some of the important cues may not be expressed, whereas others may not be relevant *in vivo*. The finer intricacies of connections depend on the interaction of axons with their continuously changing environment, so that the ultimate level of observation must be the intact, living animal. Recent advances in techniques for intracellular dye injection coupled with video-image enhancement have been harnessed brilliantly by Purves and Hadley on page 404 of this issue. The superior cervical ganglion in the neck of the rat is an accessible cluster of cells nicely suited to this technique; by using image intensification, the cell can be photographed without obviously harming it. They first expose the ganglion, fill a particular cell with fluorescent dye and photograph its branching pattern. Several days or even a month later they are able to find the same cell again and repeat the performance. They observe that the branches of the neurone change their shapes progressively over time: nerve cells are not static but are continually adapting, even in the adult animal.

It is precisely in these types of developmental systems that molecular techniques need to be applied. Increasingly, we will identify the appearance of cell surface and extracellular matrix constituents by the use of monoclonal antibodies and discover unique, regionally-localized transcription by *in situ* hybridization. Such results must be correlated with the kind of developmentally interesting events described in these papers. For example, the appearance of cell-adhesion molecules provides a powerful tool to study development both at the level of cells in the organism and at the level of regulation of gene expression in the cell (Edelman, G.M. *Proc. natn. Acad. Sci. U.S.A.* **81**, 1460; 1984).

It is becoming increasingly apparent that no single factor is responsible for the development of specific neural connections. In the intact animal, there seems to be a redundancy of guidance cues. These papers show that the intact organism must not be forgotten in the quest for molecular answers to developmental questions. □

Vision

Disparities in depth perception

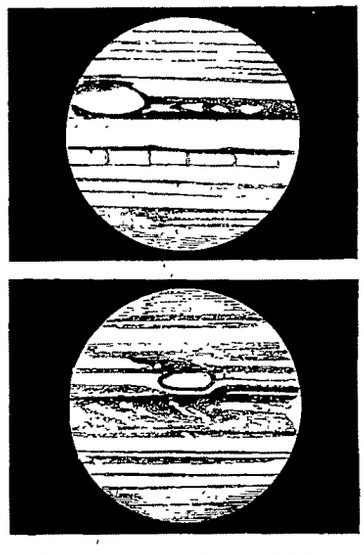
from C. Longuet-Higgins

ONE might be surprised that 150 years after the invention of the stereoscope anything remains to be discovered about stereopsis, but on page 402 of this issue Graeme Mitchison and Suzanne McKee describe a novel effect called 'interpolation', which they observe when looking at a particular kind of stereogram. In the past few years stereopsis has had an injection of new interest from two developments in particular: the demonstration by B. Julesz and J. Chang. (*Biol. Cybernet.* **33**, 107; 1976) that pattern perception is not a prerequisite for stereoscopic fusion; and the so-called 'computational paradigm' — the recognition that vision is the outcome of an elaborate neuronal computation for which our eyes supply only the input.

The foremost exponent of the computational paradigm was the late David Marr, whose book, *Vision* (Freeman, San Francisco, 1982), dealt in some detail with stereopsis. With Tomaso Poggio he produced, in succession, two alternative theories for the mechanism of stereopsis. Though the details of the process are still largely obscure, few visual psychologists would deny Marr's premise that an important preliminary to stereoscopic fusion is the matching of corresponding elements in the two retinal images — the well known 'correspondence problem' of stereopsis. Once the elements have been matched, the visual system can assess the disparities between their retinal positions and draw conclusions about the relative distances of the visible features of the scene.

The observations of Mitchison and McKee bear most directly on the question of how the visual system carries out the matching process. Most of their stereograms, presented for a time too short for the observer to scan the display, were interpreted exactly as predicted by standard stereoscopic theory. The apparent difference in depth between a pair of dots in the stereogram was simply proportional to their horizontal disparity, that is, the difference between their horizontal distances apart in the left and right retinal images. This presupposes that the elements of the two images have been successfully matched; otherwise their disparities are ill-defined.

With the stereograms that gave predictable impressions of depth, the only uncertainty in the outcome arose from alternative ways of matching the images; the choice between such alternatives seems to be broadly consonant with what is known about the 'disparity gradients' associated with matched pairs of visible elements (Burt, P. and Julesz, B. *Science* **208**, 615; 1980). But the stereograms that Mitchison and McKee find most interesting are those containing regular grids of very closely spaced points, the critical spacing being about 6′ of arc — roughly the angle subtended by adjacent grooves of a nail file held in the hand. At this spacing the visual system seems to 'lose count' of the total number of points in each image, and to estimate the position of the grid by the horizontal disparity between its two edges, ignoring any differences in the numbers of intervening points in the two images; the whole grid is seen as roughly coplanar.



Mitchison and McKee point out that their observations cast doubt on Marr and Poggio's concept of a 'coarse-to-fine vergence strategy', in which the correspondence problem is solved by progressively finer adjustments in the directions of gaze of the two eyes. It will be interesting to see whether they can develop a computational theory of the matching process with a predictive power equal to that of the theories they challenge. □

Erratum

Due to an editorial mistake in the article by A.R. Gardner-Medwin 'Potential challenge from glia' (*Nature* 16 May, page 181), it was implied that several long-established properties of glial cells were new findings reported in recent papers. The lines "including . . . . fascination" should be removed from the penultimate sentence of the first paragraph; instead they should complete paragraph 2, which will then read " . . biological cells, high permeability . .".

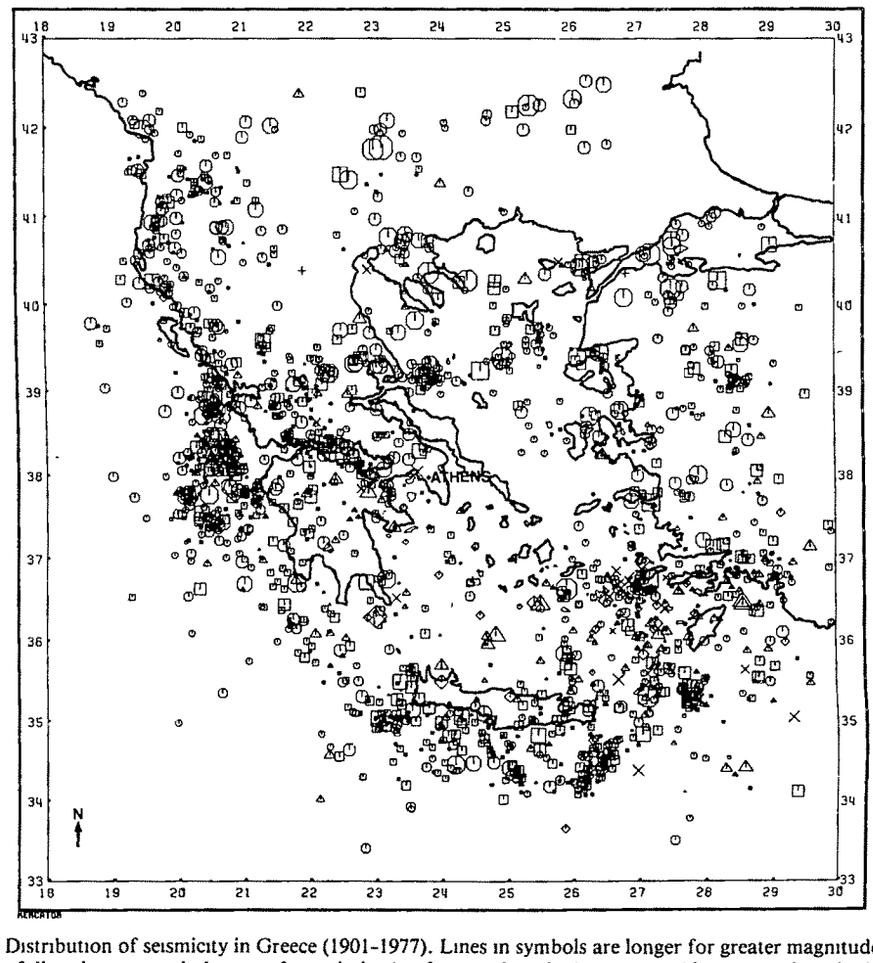
Geophysics

Electrical earthquake prediction

from Paul W. Burton

Two thousand years ago, Aristotle proposed that earthquakes were caused by subterranean winds. The Greeks are still active in the often contentious business of earthquake prediction and the team of P. Varotsos, K. Alexopoulos and K. Nomicos are well aware of controversy surrounding their work. In two papers which appeared recently in *Tectonophysics*[1,2], Varotsos and Alexopoulos have put forward their observations and ideas on variations in the Earth's electric field preceding earthquakes. They now claim to be able to forecast the magnitude and epicentre of earthquakes in Greece; to prove this they have taken the unusual step of issuing and publishing registered telegrams of their predictions, to establish a check on their work.

Phenomenological earthquake prediction is essentially the study of precursory phenomena — those events that precede an earthquake. These range from peculiarities in animal behaviour and lights in the sky to the more geophysically obvious and comprehensible precursors of increased minor seismicity. The work of Varotsos and Alexopoulos is confined to electrotelluric currents in the Earth. These naturally occuring electrical currents, which are not fully understood, are measured by probing the surface at two or more points, approximately 30 metres or more apart. They might be 'channelled' along conductors within rocks, such as fluid-filled cracks; because earthquakes involve changes in the stresses in the ground and ultimately movement along fractures, it is plausible that changes in the electrotelluric regime could indicate imminent earthquakes.



This team has monitored the telluric field at several sites in Greece since March 1981 and searched for precursory seismic electric signals (SES). Their most important conclusion is "that every sizeable earthquake is preceded by an SES and inversely every SES is always followed by an earthquake, the magnitude and the epicentre of which can be reliably predicted". These seismic electric signals are observed 6-115 hours before an earthquake, although there are distinct groupings within this range. Varotsos and Alexopoulos find no correlation between either the SES lead time or duration and the magnitude of the ensuing earthquake. However, SES from several earthquakes at different distances from a station show changes in electrical potential that are inversely proportional to distance; the SES amplitude from one seismic region recorded at one station shows a simple log-linear relationship to magnitude. Comparison of information from several stations enables calibration of earthquake signals and prediction.

Specialists and non-specialists will rake through these papers to judge how far the work is advanced and how justified are the publicized conclusions. The reproduced charts showing the SES variation with time are often confusing at first sight and do not present their information clearly. But they are reminiscent of an era when seismograms themselves looked primitive to the uninitiated.

Calibration of one station in western Greece involved collecting 20 SES measurements over four months from earthquakes exceeding magnitude 4 in the Kefalinia (Cephalonia) region and comparing them with magnitudes determined by the National Observatory of Athens. A few hundred earthquakes above this magnitude were probably recorded within 100 kilometres of Cephalonia during this time and one wonders how Varotsos and Alexopoulos dealt with all these other SESs, which they presumably also recorded. Consequently, it seems odd that there is little comment on the overall seismicity of the region. Greece is the most seismically active area in Europe (see figure), and there are clear dangers in invoking correlations between frequently occurring events. When Varotsos and Alexopoulos put forward their case, backed by registered telegrams, for having forecast 21 out of 23 earthquakes of magnitude 5 or larger that occurred near their network during eight months in 1983, they do not emphasize that one of these was forecast with magnitude 4. Taking this lower threshold, there were probably a few hundred earthquakes within a radial distance of about 1.5 degrees of the station at Pirgos in the western Peloponnese in the same period. With so many earthquakes, many will seek further verification of the correlation between particular earthquake, SES and telegram, and it would also be interesting to know how many telegrams contained information which was found subsequently to be incorrect or fortuitously correlated.

Nevertheless, many people are hopeful that a significant breakthrough has been made. This prompts consideration of the general problems raised by earthquake prediction. There will doubtless be engineering seismologists, earthquake engineers, land-use planners and government decision-makers who would hope that attention and funds are not diverted from other more practical aspects such as continued programmes of house strengthening or better building codes in earthquake-prone zones.

There is also a degree of *a posteriori* demonstration involved, which raises the

Distribution of seismicity in Greece (1901-1977). Lines in symbols are longer for greater magnitude of disturbance; symbols range from circles (surface earthquakes) to crosses (deepest earthquakes).

very real consideration of what to do when a prediction concerns an earthquake that might have substantial consequences. The Seismological Society of America has issued guidelines[3] which state that "a scientist has fulfilled his or her obligations by informing colleagues, employer and the appropriate public agencies of the prediction hypothesis, its basis, and any critiques, concurrencies or nonconcurrencies based on independent reviews". The United States also has a formal mechanism for dealing with earthquake predictions, in which the responsibility for informing both the public and public officials of vetted earthquake predictions is vested in the Director of the US Geological Survey. Community preparedness for earthquakes would also seem to be a prerequisite. In Japan, the Earthquake Assessment Committee is backed up by the Large-Scale Earthquake Countermeasures Act[4]. Greece has recently followed these leads and established, by Act of Parliament, the Organization for Aseismic Protection But when the lead time for an electrotelluric prediction is only 6–115 hours and it may relate to any part of Greece, it is hard to see what might be expected of such an organization.

So, inevitably, what should be done next? There is obviously a case for continued investment in seismological studies and earthquake source physics, but such investigations alone do not allow people to sleep well in their beds at night. In the long term, the less glamorous role of the earthquake engineer and the careful implementation of building codes and environmental hazard maps may perhaps be more substantial, if unsung, life-savers. □

Neurochemistry

New light on synapsin I

from Richard Rodnight

MANY crucial processes in the nervous system, such as synaptic transmission, involve complex interactions between the neuronal plasma membrane and components of the neuronal cytosol In the search for the molecular mechanisms of such processes, the identification and characterization of nerve-specific proteins is an essential step. There have been few successes in this area, but one that stands out is the discovery over a decade ago by P. Greengard and colleagues[1] of a major phosphorylated protein in brain, originally termed protein I, but now called synapsin I. Subsequent work by Greengard's group elegantly demonstrated that synapsin I occurs exclusively in the nerve terminals, where it is bound to the surface membrane of the synaptic vesicles, the storage sites for neurotransmitters[2]. This highly specific location clearly pointed to an important role for the molecule in some aspect of synaptic transmission (for example, the still enigmatic mechanism for transmitter release) but no precise evidence for its function emerged. Now, A.J Baines and V. Bennett, on page 410 of this issue[3], present evidence to show that synapsin I is very similar, if not identical, to an important spectrin-binding cytoskeletal protein termed brain 4.1.

The significance of this exciting discovery may reside in the fact that the analogous protein in erythrocytes, erythroid 4.1, can form stable ternary complexes with spectrin and the contractile protein actin. In the erythrocyte, these complexes constitute a stable supportive lattice at the inner face of the cell membrane and are therefore important in maintaining the shape of the cell; in nerve terminals (where spectrin and actin also occur) they may play a more dynamic role in modulating the interaction between synaptic vesicles and the terminal membrane.

To appreciate the significance of this development, we must take a closer look at both the cytoskeletal proteins and synapsin I. In the neurone a key molecule is brain spectrin[4] (also called fodrin or calspectrin), a tetramer formed from two subunits of approximate relative molecular mass (M_r) 260,000 and 265,000, antigenically related to erythrocyte spectrin (for further comment on spectrins as a family of proteins, see ref. 5). Similar to its red-cell analogue, brain spectrin binds both actin and protein 4 1 (or synapsin) and is in turn anchored through its smaller subunit to the inner surface of the neuronal membrane by yet another cytoskeletal protein, ankyrin[4]. Synapsin I consists of two subunits of approximate M_r 80,000 and 85,000 and, as noted by Baines and Bennett[3], has been mainly studied as a substrate for cyclic AMP-dependent and calcium/calmodulin-dependent protein kinases[6]. Each subunit comprises a globular head and a highly basic tail with phosphorylation sites on both domains. The basic tail of the molecule is bound to the external surface of the synaptic vesicle membrane by ionic forces that are weaker when the tail is phosphorylated by the calcium/calmodulin-dependent protein kinase[1]

It is particularly interesting that changes in the phosphorylation state of synapsin induced by electrical stimulation of nerves or by drugs that stimulate by depolarizing the neuronal membrane seem to involve mainly the calcium/calmodulin-dependent phosphorylation. This makes it possible that a consequence of such stimulation (which may be the prelude to neurotransmitter release) is to break the bond between synapsin I and the vesicle membrane Previously, the significance of this reversible binding of synapsin I to vesicles was obscure, but now that Baines and Bennett have shown that the molecule also binds to the neuronal cytoskeleton through spectrin, intriguing possibilities open up. For example, by analogy with the interaction of protein 4.1 and spectrin in erythrocytes, the binding of vesicle-associated synapsin I to brain spectrin may greatly enhance the capacity of brain spectrin to crosslink actin filaments, thereby inducing a change in the shape of the submembranous cytoskeleton and re-orientating the vesicle in relation to the terminal membrane. Further changes in vesicle orientation might follow disruption of the synapsin I – vesicle bond as a consequence of the calcium/calmodulin-dependent phosphorylation of synapsin I induced by calcium-ion fluxes in the nerve terminal. It may be significant that spectrin has binding sites for calmodulin.

Many questions need to be answered however, before precise roles for the synapsin-spectrin interaction in synaptic transmisison can be formulated. First, it should be pointed out that Bennett's group have so far been unable to demonstrate an effect of synapsin I on the crosslinking of actin by spectrin, although other workers have reported such an effect with erythrocyte protein 4.1 (ref.7). Perhaps the explanation of the discrepancy lies in differences in the function of the spectrin-actin-4.1 complex in the red cell and nerve terminal — in the former the need for a stable supporting structure is evident, whereas in the latter a more dynamic function may be envisaged, possibly involving transient states that would be difficult to detect in the test tube. Second, the precise intraneuronal distribution of brain spectrin is far from clear. As Baines and Bennett point out, spectrin is axonally transported and spectrin-like molecules can associate with intracellular organelles[8]. Moreover, the two subunits of spectrin do not always occur together and the larger subunit has a wider distribution[9], although both are needed to crosslink actin filaments. Nevertheless, there is enough evidence to suggest that spectrin, perhaps together with tubulin, could form part of a much more extensive cytoskeletal network than a purely membrane-associated structure Such a network might serve to regulate the disposition and movement of synaptic vesicles in the nerve terminals by binding vesicle-associated synapsin I

A final conundrum concerns the fact that both spectrin-like molecules and proteins immunologically related to erythrocyte 4 1 have a wide distribution in cells; indeed

Goodman *et al.*[10] present evidence indicating that, at the level of the light microscope, the distribution of spectrin and 4.1 (as detected by an antibody to erythrocyte 4.1) in the cerebellum are identical and extend to neuroglia as well as neurones. The latter contrasts with the virtually exclusive localization of synapsin I in the nerve terminal[1]. These results cannot be explained purely on the basis of the very high concentration of synapsin I in the nerve terminal (where it constitutes about 6 per cent of the vesicle protein), because immunocytochemistry using anti-synapsin immunoglobulin confirms the restricted location. Therefore, it seems likely that synapsin I is a highly specialized form of 4.1 found only in neurones. This conclusion confirms the overwhelming impression that synapsin I must play a unique role in some aspect of synaptic transmission. □

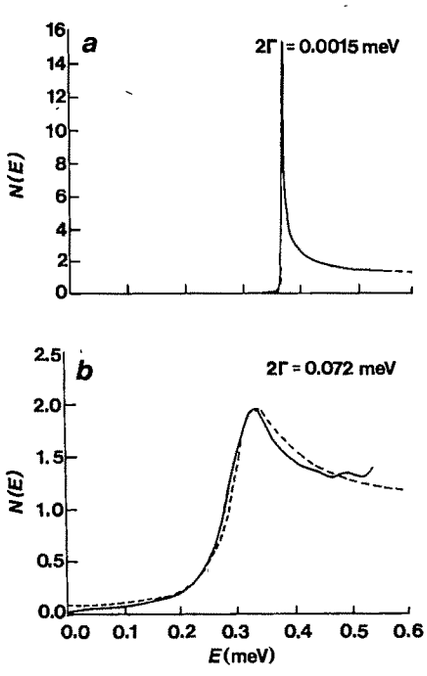
Solid-state physics

How superconductivity fades near metal–insulator transitions



from W.L McLean

ALTHOUGH the importance of quantum mechanics in solid-state physics has been well established for many decades, it came as a rude surprise about five years ago that startling quantum effects in metallic conduction had been overlooked. Unusual behaviour and bizarre predictions near the metal-insulator transition have recently come to be expected. Further challenging questions arise when the system can also be superconducting. One of these that is less innocent than it first seems is whether superconductivity can persist into the insulating side of the transition. If not, does it die out right at the transition or while the system is clearly still on the metallic side? R.C. Dynes, J.P. Garno, G.B. Hertel and T.P. Orlando have recently shed new light on this area by measuring electron tunnelling in the granular aluminium system (*Phys. Rev. Lett.* **53**, 2437; 1984).

Granular aluminium, which is a mixture of grains of metallic aluminium and amorphous aluminium oxide, is one of a number of systems from which a series of specimens, ranging from pure metallic to pure insulating, can be prepared by varying the metal volume fraction. The granularity, which can be seen by transmission electron microscopy, is clearly marked in the middle range of concentrations, where the metal-insulator transition occurs. Many theoretical models that attempt to explain properties of granular metals do explicitly take this granularity into account.

A very different interpretation that has been used by Dynes *et al.*, among others, is that the properties of granular aluminium can be interpreted as if the system were an amorphous metal in which the disorder is on an atomic scale. This outlook is commonly justified by the assumption that all relevant length scales are larger than the grain size, and it is in this framework that the importance of the new tunnelling measurements becomes apparent.

The experiments use the technique of electron tunnelling at low temperatures of approximately 0.06 K, which is much less than the superconducting transition temperature, to measure the density of states of the elementary excitations (quasi-particles) of the superconductor. In low resistivity specimens it is not surprising that

The density of states, $N(E)$ deconvoluted from the experimental data. The dashed line is a BCS density of states broadened by the value of Γ shown in each figure. The 'lifetime' of a quasi-particle is $\hbar / \Gamma$. *a*, Specimen with small broadened effects; *b*, specimen very close to metal-insulator transition (modified from Dynes, R.C. *et al Phys. Rev. Lett.* **53**, 2437; 1984).

granular aluminium behaves exactly as an ordinary superconductor with a sharp asymmetrical peak in the density of states clearly defining the edge of an energy gap, in good agreement with the Bardeen, Cooper, Schrieffer (BCS) theory of superconductivity. At higher resistivities very close to the metal-insulator transition, however, the density of states is no longer zero at low excitation energies and the discontinuity is replaced by a broad smooth maximum.

Dynes *et al.* have successfully fitted their data with a BCS density of states modified to take into account broadening caused by a finite lifetime of the quasi-particles in the granular superconductor. In this case the lifetime is limited by inelastic scattering processes, which have been of great interest recently in connection with the tendency of electron states to become localized as the metal-insulator transition is approached. The values of the inelastic scattering rates deduced from the tunnelling measurements are consistent with those deduced from a different experimental approach, measurement of the magnetoresistance.

Thus, superconductivity seems to die away near the metal-insulator transition by a gradual lifetime broadening of the density of states concomitant with the appearance of quasi-particle states in the region where there is an energy-gap in lower resistivity specimens. A particular oddity of these results is that they imply that moderately strong indications of superconductivity still appear close to the energy at which the sharp peak occurred in the low resistivity specimens. This may be connected with the long tails reported by Dynes *et al.* in the resistive transitions of the highest resistivity specimens.

Further intriguing questions are: first, what happens at much lower temperatures when the lifetimes of the quasi-particles should become longer? Does the full BCS gap reappear? The implication is that the closer one approaches the metal-insulator transition, the lower must the temperature be in order to see the full superconductivity. Second, does some inelastic scattering mechanism peculiar to the granular structure come into play or are the mechanisms found in amorphous metals still operating in the granular system?

Although the new results seem to provide firm support for the quasi-homogeneous medium approach, it still remains to reconcile this point of view with approaches that do assume the granularity to be relevant. These include those workers who seek to explain the properties of granular metals in terms of percolation through an assembly of randomly linked grains, and those focusing on the consequences of electrostatic charging of the grains on the stability of the superconductivity. □

Explanation of the inward displacement of Io's hot plasma torus and consequences for sputtering sources

J. A. Linker,* M. G. Kivelson,* M. A. Moreno* & R. J. Walker

Institute of Geophysics and Planetary Physics and * Department of Earth and Space Sciences, University of California, Los Angeles, California 90024, USA

Radial profiles of the ion density and flux-tube content in the Io torus have peak values inside Io's orbit, even though Io is the effective source of these ions. Formation of an inward peak constrains either the velocity distributions or source regions of sputtered neutrals. A further constraint is that the ionization of neutrals on trapped trajectories that return to Io's surface must be limited. A dominant sulphur source is most easily reconciled with these constraints.

Io, the innermost of the four Galilean satellites, has a dense torus of plasma associated with it. This torus, perhaps the most intriguing feature of Jupiter's magnetosphere, has been the subject of intensive research and debate. Recent ground-based measurements of the torus[1], as well as measurements from the Voyager spacecraft[2,3], have shown that both the ion density (Fig. 1*a*, *b*) and NL^2, the flux-tube content (Fig. 1*c*), attain their maximum values as functions of radial distance from Jupiter well inward of Io's orbit, with NL^2 falling off sharply inside ~5.6 jovian radii (R_J).

Many features of the radial profiles can be understood in terms of radial diffusive transport[4-7]. Because diffusion driven by macroscopic processes in planetary magnetospheres is accomplished by the interchange of magnetic flux tubes, NL^2, proportional to the number of ions per unit magnetic flux, is the diffusing quantity[4]. (The parameter L labels a field line and, in a dipole field, L is the distance in planetary radii from the centre of the planet to the equatorial point on the field line. N is the number of ions per unit L.) The radial profile of NL^2 is consistent with diffusive transport of ions only if their source attains a maximum value near 5.6-5.7 R_J. Centrifugal forces drive rapid outward diffusion, consistent with the relatively slow outward decrease of NL^2 beyond 5.7 R_J. Slow inward diffusion driven by atmospheric winds explains the sharp decline inward from 5.6 R_J, but the heavy ions that form the torus must originate from matter on Io itself. The main purpose of this paper is to explain why, although Io is the actual source of particles, the peak in NL^2 occurs inside its orbit. Specifically, we have calculated the trajectories of neutral particles ejected from Io and have examined the conditions under which they tend to be ionized inside Io's orbit. We find that the requirement of a localized peak constrains either the spectrum of sputtered neutrals or their source locations on Io, or both. A further constraint is placed on the ionization of neutrals on trapped (non-escape) trajectories.

Calculations and modelling

It is generally agreed that the ions in the torus originally are ejected from Io as neutrals forming neutral clouds extending far from Io. These neutrals are ionized eventually to form the torus[8-10]. This sequence suggests a possible explanation for the peak in NL^2 inwards of Io's orbit; perhaps the trajectories of neutrals are such that they tend to be inward of Io's orbit at the time they are ionized[1]. We have investigated this possibility using simple models for the production of ions from the neutrals. We have assumed that neutral particles are ejected from Io's equator with initial positions spaced uniformly in longitude and separated by 5° (see Fig. 2*a*). At each initial position, 100 neutral particles are 'launched' radially, with specified initial velocities, each set of particles having a distribution of lifetimes of the form (Fig. 2*b*)

$$P(t)\,dt = (dt/\tau)\exp(-t/\tau) \quad (1)$$

We ignore the consequences of misalignment of magnetic and rotational poles. Thus, the position of a neutral at the end of its life defines the radial coordinate of a newly created ion. To be physically meaningful, it is important that a distribution of lifetimes be used for the model, because if only the average lifetime were used there would be no way for the particles from a given source position with given velocity to spread in radial-position.

At each initial position, trajectories were calculated for velocities in the range 1.0-4.0 km s^{-1} in increments of 0.1 km s^{-1}. We used an orbit calculation program (OBCAL) that integrates the equations of motion for the particles, taking into account the gravitational forces of Jupiter and Io, the other three Galilean satellites and the J_2 term in Jupiter's gravitational potential. (The Galilean satellite trajectories are modelled as slightly inclined ellipses.) Ephemeris data for the Galilean satellites were provided by the Jet Propulsion Laboratory (JPL). The program was tested by comparing calculations of the positions of both Io and the Galileo spacecraft with calculations performed by JPL; discrepancies were $<5\times10^{-3}$ R_J.

Sputtering, in which charged particles collide with neutral matter and neutral atoms and molecules are emitted, is believed to be the dominant process responsible for ejecting matter from Io[10]. To calculate the number of particles at a given velocity, we have assumed velocity distributions expected for sputtering. The particles are assumed to come from the surface of Io; however, this should not be construed as eliminating the possibility that the particles could originate from the atmosphere or exobase. As any assumed surface source distribution maps to a shifted velocity distribution at the atmosphere or exobase, our solutions also apply to the mapped sources at these altitudes. Note that all our sources are located at Io's equator and Io is assumed to lie in the magnetic equatorial plane; these assumptions serve to make the calculation manageable. High-latitude particles emitted radially would have similar trajectories except that their orbits would be inclined with respect to the spin equator. Because energy is used to incline the trajectory rather than to change the apsides of the trajectory, high-latitude particles in general need higher initial velocities to escape and to achieve the same eccentricity as equatorial particles. Therefore, the trajectories of high-latitude particles should be similar to those of equatorial particles, except that the orbits will be inclined and higher initial velocities will be necessary to achieve the same displacement from Io's orbit. By neglecting the tilt of Jupiter's dipole, we do not take into account that the L shell of

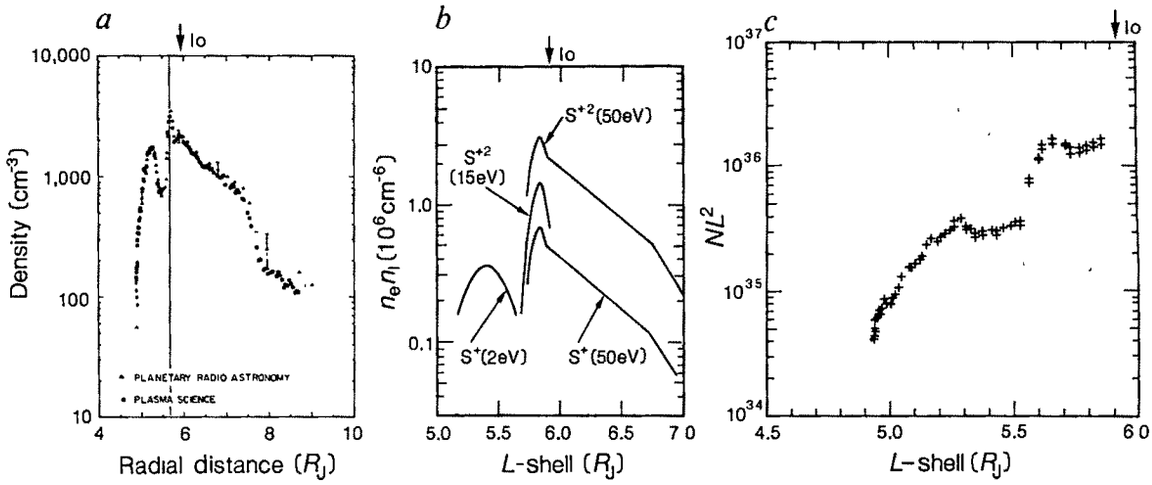

Fig. 1 *a*, Radial profile of *in situ* measurements from the Voyager spacecraft of charge density in the Io torus. The peak occurs well inside Io's orbit, at ~5.7 R_J (adapted from ref. 3). *b*, Radial profiles of ground-based measurements of sulphur-ion densities. Again the peak occurs inside of Io's orbit (adapted from ref. 1) *c*, Radial profile of NL^2, proportional to the total number of ions per unit magnetic flux, based on measurements from the Voyager spacecraft. This function, conserved in adiabatic transport, enters the canonical form of the equation for radial diffusion. The peak in NL^2 occurs at 5.6–5.7 R_J and thus requires a source of ions in this region. There also seems to be a 'plateau' at 5.2–5.3 R_J in the cold torus (this also appears as a small peak in *a* and *b*; adapted from ref. 2).

a newly created ion is necessarily the same or larger than the radial distance at which ionization occurs. However, because the electron density (and hence the ionization rate) is much higher in the centrifugal equator[11], neutrals will tend to be ionized when they are in the centrifugal equator. The change in L shell is then very slight (<0.02 R_J) and should not have any significant effect on the profiles shown here.

Results

Unless otherwise noted, our calculations assume a spatially uniform probability of ionization. First, we consider a mean lifetime of 40 h, appropriate for sulphur atoms being ionized by electron impact near Io. This is the lifetime that results if we use commonly accepted rate coefficients[12–14] and an electron density of ~2,000 cm^{-3}. Figure 3*a* shows the radial distribution of new ions from neutral particle sources distributed from 0 to 90° in longitude. Neutral velocities are assumed to obey what is called a thermal spike velocity distribution[15]

$$f(v)\,dv \propto v^3 \exp(-mv^2/kT)\,dv \qquad (2)$$

and only neutrals above the escape velocity ($v > 2.3$ km s^{-1}) are considered. (Here T, an arbitrary parameter characterizing the steepness of the distribution and not related directly to the actual temperature of the source, was chosen as 4,000 K. The thermal spike velocity distribution is only an approximation to observed sputtering spectra. For example, values of 2,000 3,600 and 5,200 K have been used to represent spectra for sputtering of various materials[16].) Note that a peak in density occurs between 5.6 and 5.7 R_J as required by the data. One should also recognize that the plotted profiles in Figs 3–5 are proportional to the source rate in a diffusion equation for NL^2.

Figure 3*a* shows that sputtered neutrals above the escape velocity with a plausible velocity distribution produce the spatial localization needed for a source of Io torus ions. The neutrals that tend to contribute most to the ionization peak between 5.6 and 5.7 R_J are those with a velocity slightly above the escape velocity (2.3–2.5 km s^{-1}). This can be understood as follows: particles that barely escape from Io, once away from Io, are on nearly circular trajectories around Jupiter and thus tend to be ionized at roughly the same distance independent of the lifetime of the neutral. Those neutrals that are injected inward thus tend to be ionized inwards of Io's orbit in a fairly narrow range of radial position. For higher injection velocities, neutrals tend to be on more elliptical trajectories and are thus ionized with a wider spread in radial position. As the thermal spike velocity distribution heavily favours injection of neutrals at lower velocities, neutrals with injection velocities favourable for formation of the inward peak tend to dominate the escaping particles. The 0–90° region of longitude is also favourable for formation of the desired peak because neutrals ejected from this region proceed on trajectories inwards of Io's orbit. However, as will be shown later, a source of neutral particles spread uniformly in longitude can also form the required inward peak. Our parameters are chosen to describe sulphur; however, because the results are relatively insensitive to lifetime they probably apply to oxygen as well.

Note that when all important gravitational forces are considered, particles with velocities as low as 2.3 km s^{-1} can escape Io even though the escape velocity from Io as an isolated body is almost 2.6 km s^{-1}. The number of neutrals ejected above the escape velocity gives the only constraint on the T parameter in the thermal spike velocity distribution. With $T = 4{,}000$ K, as in this calculation, ~4% of the neutrals escape. As will be shown below, this gives an adequate supply rate of neutrals.

Thus far, we have considered only neutral particles on trajectories that allow them to escape from Io. However, there is nothing in our model to prevent the ionization of neutrals on trapped trajectories (particles that, if not ionized, ultimately fall back to the surface of Io). Because the sputtering velocity distributions favour low velocities, a large fraction of neutrals will be on these non-escape trajectories. If we consider the same velocity distribution as in Fig. 3*a* with the same longitudinal region of sources, but include the ionization of neutral particles below the escape velocity, the radial distribution of newly created ions shown in Fig. 3*b* is formed. A small peak forms between 5.6 and 5.7 R_J, but contrary to the observations, a sharp peak forms at 5.9 R_J. This sharp peak forms because many more neutral particles are on trapped trajectories than on escape trajectories. Because of Jupiter's gravitational force, these low-velocity particles get much farther away from Io and take much longer to fall back to Io's surface than if only Io's gravitational force were considered. We are presently working on calculations of the neutral density near Io and find that the requirement of an adequate source rate of neutrals above the escape velocity implies that a dense neutral cloud (~10^5–10^6 cm^{-3}) forms within 3 Io radii of the surface of Io. For the case shown in Fig. 3*b*, a source rate of 3×10^{28} ions s^{-1} into the torus implies that $>10^2$ ionizations s^{-1} occur near Io, greater by an order of magnitud

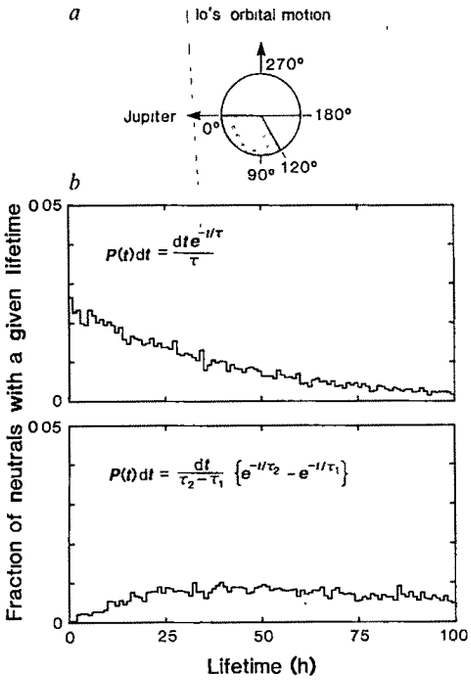

Fig. 2 *a*, Coordinate system for neutrals ejected from Io. The circle represents Io seen from above Io's orbit plane. For the calculations, particles were ejected uniformly in longitude with a separation of 5° between each position. The shaded area of the diagram shows the region where sulphur volcanoes are observed on Io[25]. Note that the coordinate system is right-handed, opposite to the one used by ref. 25. *b*, Histogram of a typical distribution of lifetimes, generated for a mean lifetime against ionization of 40 h for a spatially uniform probability of ionization. The distribution gives the probability that an atom survives a time t and is ionized between t and $t+dt$ The radial position of a neutral at the end of its life defines the radial coordinate of the newly created ion c, As *b* for the case of a molecule that is first dissociated and the products subsequently ionized: τ_1, mean lifetime for dissociation of S_2, was assumed to be 46 h (see text); τ_2, the mean lifetime for ionization of S, is 40 h. A spatially uniform probability of electron impact is assumed. As the probability of ionization in the first few hours is small, the number of ions formed from neutrals on trapped trajectories is relatively insignificant. Because any S_2^+ ions formed are lost quickly by dissociative recombination, only S_2 molecules that are first dissociated contribute significant numbers of ions to the torus.

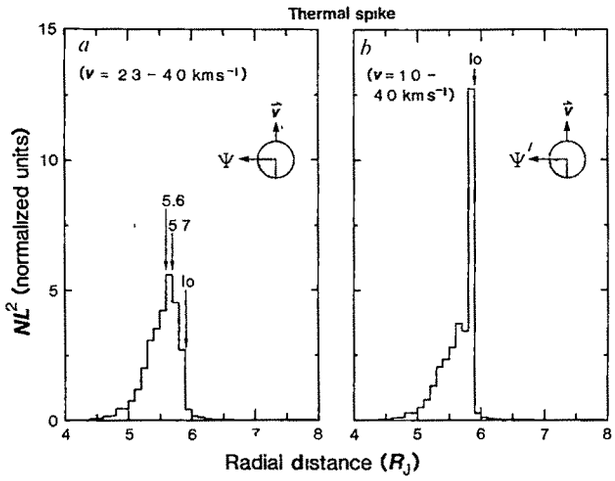

Fig. 3 *a*, Radial profile of NL^2 divided by the total number of particles, calculated for neutrals ejected from longitudes between 0 and 90° on the surface of Io with a thermal spike distribution of velocities, considering only velocities above the escape velocity A distribution of lifetimes as shown in Fig. 2*b* with a mean lifetime of 40 h was used for the neutrals. The peak at 5.6–5.7 R_J is the major feature required of a source of Io torus ions. For neutrals above the escape velocity, any velocity distribution of ejected neutrals that falls off rapidly enough with increasing velocity will cause the inward peak in NL^2 to form. A rapid fall off with increasing velocity is in fact a characteristic of velocity distributions expected for sputtering. This figure and all succeeding figures show possible source profiles of Io torus ions. The profile of the total ion density would be modified by the effects of diffusive transport, but the peak would remain in the same location. *b*, As *a* except that neutrals with velocities below the escape velocity are included A sharp peak forms at 5.9 R_J, in contrast with the observations. If we normalize the number of neutrals above the escape velocity to be 2×10^{28} s^{-1}, an adequate source rate[20] of 3×10^{28} ionizations s^{-1} in the torus is obtained, but the profile shown here would require 10^{28} ionizations s^{-1} within 3 Io radii of Io's surface. Observations place a limit of 10^{27} ionizations s^{-1} of sulphur and oxygen atoms near Io. Thus, for consistency with observations, some process must limit ionization of sulphur and oxygen atoms on trapped trajectories near Io Injection of S_2 neutrals as the dominant source of torus ions is consistent with this requirement. The profiles shown can be regarded as the source rate in a diffusion equation governing NL^2.

than the limit placed on ionization of sulphur and oxygen atoms in the vicinity of Io by observation[17].

As the Io torus requires an injection rate of $2\text{–}7\times10^{28}$ ions s^{-1} (refs 18–20) and the sputtering velocity distributions greatly favour the production of particles on trapped trajectories, some process must limit the ionization of atoms on these non-escape trajectories. The ionization limit is required both to explain the formation of an inward peak and to be consistent with the observations of limited ionization near Io. One way that the ionization of atoms near Io could be limited is if the predominant sputtering products are molecules. If an electron impact is required to first dissociate the molecule, and the products are ionized by subsequent electron impacts, then neutrals on trapped trajectories would fall back to the surface of Io before they could become ionized.

For estimates of the importance of this two-step process we consider the sputtering of sulphur. Sulphur sputtered from the surface of Io has often been ignored as a source of torus particles because some estimates[10,15] indicated that sputtering yields for this element would be small compared with those for SO_2. These sputtering yield estimates were based on the assumption that the binding energy is much higher for sulphur than for SO_2 (ref. 10). However, recent experiments[21] have shown that sulphur gives anomalously high sputtering yields of the order of 10^4–10^6 per incident ion when bombarded with 30–300 keV He^+ ions, a yield as much as five orders of magnitude greater than estimates for the sputtering yield of SO_2 (ref. 10). The experiments indicate that the predominant product of sputtering of sulphur is S_2, with some larger sulphur molecules present as well. S_2 would dissociate and ionize as follows (the mean lifetime, τ, is shown for each process); because lifetimes for S_2 ionization and dissociation were not available, lifetimes for O_2 were substituted[22]

$$S_2 + e^- \rightarrow S + S + e^- \quad (\tau_1 = 46\text{ h}) \tag{3}$$

$$S + e^- \rightarrow S^+ + 2e^- \quad (\tau_2 = 40\text{ h}) \tag{4}$$

On the other hand, the S_2 molecule itself can be ionized

$$S_2 + e^- \rightarrow S_2^+ + 2e^- \quad (\tau_3 = 32\text{ h}) \tag{5}$$

There is no observational limit on the ionization per second of S_2, as the observations near Io constrained only the ionization rates of atomic sulphur and oxygen. However, experiments with O_2^+ and NO^+ show that dissociative recombination occurs rapidly for these molecules for electron temperatures in the range 0.045–4 eV (ref. 23). Extrapolation of the dissociative recombination rates to 5 eV gives a lifetime in the range 4–9 h (for an electron density of 2,000 cm^{-3}), which is small compared with the ion diffusion time (30–100 days). Thus, the reaction

$$S_2^+ + e^- \rightarrow 2S \quad (\tau_4 = 4\text{–}9\text{ h}) \tag{6}$$

proceeds sufficiently rapidly that any S_2^+ ions formed will be converted into neutrals. The neutrals will then have the corotation velocity and will quickly leave the torus. Therefore, S_2^+ ions

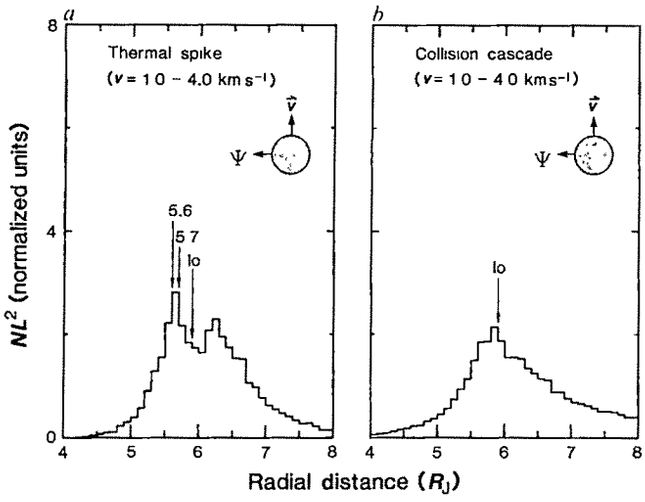

Fig. 4 *a*, Radial profile of NL^2 divided by the total number of particles. For this and all succeeding figures, the distribution of lifetimes described in Fig. 2*c* was used. Neutrals were ejected from all longitudes of Io, with a thermal spike distribution of velocities (see text). The range of velocities was 1.0–4.0 km s^{-1}. The required inward peak forms at 5.6–5.7 R_J. This is true for any velocity distribution that peaks below the escape velocity and falls off rapidly with increasing velocity. *b*, As *a* but for the limiting case of a collision cascade distribution (see text). A peak at Io is formed that is inconsistent with the required source This velocity distribution does not fall off rapidly enough to form the inward peak, but does provide a direct source of neutrals over a broad radial range.

will not add significantly to the NL^2 profiles, and we need consider only those neutrals that are first dissociated and then ionized.

For a spatially uniform probability of electron impact, the probability of a neutral's being ionized between time t and $t+dt$ following an earlier dissociation is of the form:

$$P(t)\,dt = \frac{dt}{\tau_2 - \tau_1}\left(e^{-t/\tau_2} - e^{-t/\tau_1}\right) \qquad (7)$$

If we generate neutral lifetimes using this probability distribution (Fig. 2*c*) and we use the thermal spike velocity distribution that we used in Fig. 3, but with neutral sources at all Io longitudes, we obtain the radial distribution of newly created ions shown in Fig. 4*a*. As the dissociation of the molecules must occur before the individual atoms are ionized, only a fraction of particles on trapped trajectories are ionized and the peak at 5.9 R_J is reduced. A clear peak of ion density forms at 5.6–5.7 R_J, as required by the data.

For the results shown in Fig. 4*a*, we have looked at a specific mechanism that can limit the ionization rate near Io if the source is rich in S_2. However, other processes can limit the ionization rate near Io independently of the neutral species. Because the neutral cloud within 3 Io radii of Io's surface has neutral densities orders of magnitude higher than the electron density, the physics must differ greatly in the neutral cloud from elsewhere in the torus. Other, possibly more important, mechanisms may limit ionization rates for neutrals in the dense cloud, and thus decrease the ionization probability for particles on trapped trajectories. Based on the spectroscopic observations, such a limitation certainly occurs. With a limitation on ionization near Io, any neutral species with a velocity distribution that peaks below the escape velocity and falls off rapidly enough with increasing velocity will form the inward peak.

Some workers[15,16] believe that the thermal spike distribution we have assumed is accurate only for high energy (keV–MeV) sputtering ions. If neutrals are sputtered by corotating ions, a collision cascade velocity distribution of the form

$$f(v)\,dv \propto v^3\,dv/(v^2+v_0^2)^3 \qquad (8)$$

may give a better representation. Here v_0 is the velocity corresponding to the binding energy. A relatively flat velocity distribution for neutrals does not form an inward peak if sources are distributed uniformly around Io's equator. The steepest velocity profile allowed by equation (8) corresponds to $v_0 = 0$; in Fig. 4*b* we have plotted the ion distribution obtained for this limiting case. As can be seen in Fig. 4*b*, a small peak at Io is formed. Even in the limiting case, a collision cascade distribution does not fall off rapidly enough to produce the required inward peak.

The results shown in Fig. 4 were calculated for sources independent of Io longitude, but there are reasons why ejection of particles from Io may be asymmetrical in longitude. For example, the nature of the plasma flow around Io may lead to preferential regions of access for the sputtering ions[24]. This asymmetry would be highly dependent on the character of the interaction between Io and the torus plasma, which at this time is not well understood. An asymmetry in the source locations of sputtered particles could also occur if the dominant source of the neutrals on the surface were localized. SO_2 is found at roughly all longitudes; however, sulphur is confined to the region from 0 to 120° as illustrated in Fig. 2*a* (ref. 25). As mentioned previously, recent experiments[21] have shown that sulphur gives very high sputtering yields, orders of magnitude greater than the sputtering yields estimated for SO_2. Such large sputtering yields suggest that sulphur may be the dominant neutral injected into the torus. Furthermore, some calculations[26] suggest that a 4:1 injection ratio of sulphur to oxygen is consistent with the observed ion partitioning. If we consider sulphur neutrals with the thermal spike velocity distribution coming from the sulphur-rich regions on Io, a very sharp peak is formed (see Fig. 5*a*). Even for a collision cascade velocity distribution, the required peak is still formed if the sources are localized in the sulphur-rich regions (Fig. 5*b*).

Discussion

Our results show that the requirement that neutrals sputtered from Io must ultimately form a distribution of ions with a peak in NL^2 near 5.7 R_J, substantially constrains models of the source. Ionization of neutrals on trapped trajectories must not contribute significantly to the ion population. The velocity distribution of ejected neutrals must fall off sufficiently rapidly with increasing velocity so as to favour heavily those particles near the escape velocity, or the source must be localized in longitude, or both. These requirements are easily reconciled with sulphur being the dominant neutral injected into the torus. S_2 sputtered from the surface of Io must first be dissociated before it is ionized, limiting the ionization of atomic S near Io. S_2^+ ions that are formed will be lost rapidly by dissociative recombination. The sulphur-rich volcanoes are, in fact, confined to longitudes favourable for producing the observed peak[25].

The high sputtering yields for sulphur[21] allow a velocity distribution that falls off rapidly with increasing velocity and yet still gives an adequate source rate for maintaining the torus. For example, for a 3% escape fraction, 20% surface coverage and incident H^+ ions with energies >220 keV, it has been estimated previously[10] that a sputtering yield of one would give 10^{22} neutrals per second injected into the torus. A 4% escape fraction is obtained for the thermal spike velocity distribution of equation (2) with $T = 4{,}000$ K. The measured sputtering yield of 10^6 for sulphur would then imply an injection rate of $>10^{28}$ s^{-1}, approximately the rate required from other arguments[10,18,20]. This rate estimate may be low, as bombardment by heavier ions could lead to even higher sputtering yields, and lower energy ions (corotation energy to 220 keV) will undoubtedly contribute significant additional sputtering. Because flux-tube interchange diffusion produces strong outward mixing, the proposed sulphur source would produce a hot outer torus dominated by sulphur ions. It is not known whether sputtering of sulphur at Io will be as efficient as in the laboratory. In particular, the sputtering efficiency seems to increase with increasing source temperature[21]. In this regard, the 'hotspots' seen on Io[27] may be areas of more efficient sputtering. The

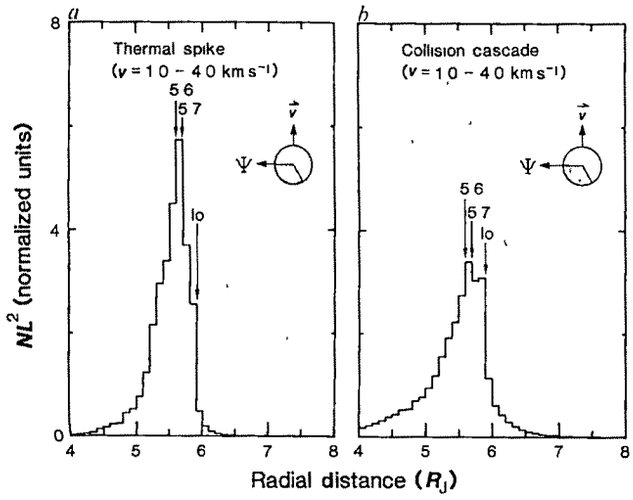

Fig. 5 *a*, As Fig. 4*a* except that the neutrals were ejected only from the sulphur-rich regions of Io[25] shown in Fig 2*b*. A sharper inward peak is formed. As recent experiments[21] indicate that sulphur gives anomalously high sputtering yields, the sulphur-rich regions may be the predominant source of Io torus ions. Ionization occurring in a narrow range of radial location near 5.7 R_J as shown here could explain the narrow, 'ribbon-like' structure seen in ground-based observations of sulphur ions[1]. *b*, As *a*, except that a collision cascade velocity distribution with a binding energy of 0.1 eV was used. An adequate inward peak is still formed, even though the fall off of the velocity distribution is much more gradual. Recent experiments[21] on the sputtering of sulphur have shown that for sputtering by 3-9 keV Ar^+ ions, an effective surface binding energy of 0.1–0.3 eV is appropriate for sulphur.

longitudinal locations of the hotspots are also favourable for formation of the inward peak.

It is more difficult to reconcile our results with SO_2 as the dominant source. The requirement that the velocity distribution fall off rapidly with velocity, coupled with the much lower sputtering yields for SO_2, make it unlikely that a dominant SO_2 source on the surface of Io could provide the necessary escape rates to populate the torus. Although our results do not eliminate sputtering from a thick SO_2 (or sulphur) atmosphere as the dominant source, they do place constraints on this possibility. It has been noted[10,28] that sputtering from such an atmosphere can easily maintain the required total source rate of neutrals. However, the velocity distribution expected for this source[28] (similar to a collision cascade distribution) does not fall off rapidly enough for the neutrals to form the inward peak unless the source is longitudinally asymmetrical. The primary sputtering product from a thick SO_2 atmosphere (density of $\sim 10^{10}$ cm^{-3} at the surface) would be atomic oxygen[10,20], so again a mechanism that limits the ionization of neutrals near Io would be necessary. If the source is a thick SO_2 atmosphere, sputtering models predict more than adequate oxygen escape rates but they encounter problems in obtaining even the minimum required sulphur escape rates[10,20]. A thick atmosphere on the dayside of Io coupled with a thin atmosphere on the nightside that allows sputtering of sulphur from the surface of Io could resolve this dilemma.

In our calculations, assumptions regarding lifetimes for neutrals ignore any variation of ionization probability with position. Thus, we have effectively assumed a uniform electron density (n_e) and temperature (T_e) distribution throughout the torus. In actuality, n_e and T_e drop sharply inside 5.7 R_J, making ionization in the region of the observed peak more likely. By using a model with uniform n_e and T_e, we are able to investigate the question of whether or not the peak can form inward of Io solely because neutral particles tend to spend most of their time in this region. As our calculations have shown, there are physically plausible scenarios in which neutral particles will tend to be ionized to form a peak inwards of Io, even for uniform distributions of n_e and T_e. This then explains how the peak in the ion density could form inwards of Io in the first place. Heating of electrons by collisions with pickup ions would then, in turn, produce the observed radial variation of T_e (ref. 29). The T_e variation would increase the probability of ionization near the peaks of the derived profiles of newly ionized neutrals. Thus, in a self-consistent calculation, the locations of the peaks we have obtained would not change, but their steepness would be enhanced. We believe that 'the ribbon' of S(II) emission observed[1] near 5.7 R_J may be explained in this way. We have not taken into account the possible effects of collisions on the trajectories in our calculations. Although collisional processes could introduce some spread into the trajectories of the neutrals, our basic result, that the inward peak forms if the distribution of neutral velocities falls off rapidly with increasing velocity, should remain unaffected.

By assuming that the dominant neutral source of torus ions is S_2, we showed that only small numbers of ions are created near Io as necessary for consistency with observations. The limitation to the ionization rate near Io can be achieved in other ways. For example, the presence of the neutral cloud near Io can limit the amount of ionization. Within 3 Io radii of Io's surface, the density of sputtered neutrals will be much greater than the electron density, so it is possible that ionization near Io is limited by the availability of the electrons or by electron cooling resulting from interaction with the neutral cloud. A cooler electron temperature in the Io flux tube has in fact been observed[30]. If the presence of the neutral cloud does in fact limit ionization and other neutral species meet the constraints on the velocity distribution and/or source locations for formation of the inward peak, then S_2 need not be the dominant neutral injected into the torus.

Similar trajectory calculations have been performed previously for sodium[31,32] and a model, including the electron density and temperature profiles, has been published for oxygen[33]. The latter calculation provides useful insight into the supply of ions to the torus, but it does not explain why the radial profiles of ion density and NL^2 peak inwards of Io's orbit. In the cited calculation[33], the measured n_e and T_e profiles were assumed and then the position where the particles were ionized was determined. The calculated radial profile of newly created ions obtained in ref. 33 peaks roughly at Io's orbit (Figure 8 of ref. 33), farther out than the peak in the ion-density data. As electron and ion number densities must peak in the same location, the electron distribution assumed for the calculation in ref. 33 would not be maintained in a steady state. Furthermore, because the newly created pickup ions are responsible for the radial variations of n_e and T_e, a calculation that assumes observed radial profiles for these quantities does not demonstrate how the peaks developed inwards of Io in the first place. In addition, we note that the calculated[33] peak in the ion-creation rate was obtained for particles launched from the exobase (at 2,600 km) with a velocity of 2.6 km s^{-1}. This velocity maps roughly to a velocity of 3.0 km s^{-1} for a particle leaving the surface of Io. As seen in Fig. 4*b*, when velocities much larger than the escape velocity become important, the inward peak does not form for sources distributed uniformly in longitude. In fact, for a velocity of 3.0 km s^{-1}, even a source restricted in longitude will not form the inward peak. Thus it seems that the neutral velocity chosen for the calculations of ref. 33 is too high to form a peak much inside Io's orbit. Finally, we note that because neutrals with velocities below the escape velocity were not considered in ref. 33, the important effects of ionization of neutrals on trapped trajectories were ignored in their calculations.

Conclusions

We have investigated models for the formation of the peak in ion density and NL^2 inwards of Io's orbit. We summarize our findings as follows: (1) Neutral particles with velocities above the escape velocity sputtered from sources independent of Io longitude will form a peak inward of Io between 5.6 and 5.7

R_J, provided that the velocity distribution drops off sufficiently rapidly. We have shown that a thermal spike velocity distribution (equation (2)) produces such a peak whereas distributions that fall off as v^{-3} or less do not create the required peak. (2) If the sputtering sources are confined to longitudinal regions on Io where sulphur predominates[25], the inward peak is obtained even for less steeply decreasing velocity distributions (such as collision cascade). If a thermal spike velocity distribution is used, a sharper inward peak is formed. (3) Velocity distributions predicted for sputtering of neutrals place many more particles on trapped (non-escape) trajectories than on escape trajectories, so an adequate source rate[20] of ions in the torus ($2\text{–}7\times10^{28}$ s^{-1}) implies that a dense neutral cloud (10^5–10^6 cm^{-3}) will form within 3 Io radii of Io's surface. Ionization of atomic sulphur and oxygen in this cloud must be limited by some process to satisfy observational constraints on ionization[17] and for formation of the inward peak. (4) The above results are more readily reconciled with S_2 being the dominant neutral injected into the torus rather than SO_2 or O. In particular, the large sputtering yields recently demonstrated for sulphur[21] would allow sputtered sulphur to have a steeply decreasing velocity distribution and still give an adequate source rate of neutrals into the torus. In addition, the sulphur-rich volcanoes on Io are confined to a longitudinal region favourable for producing the inward peak[25]. A dominant SO_2 source on the surface is unlikely, because if SO_2 were sputtered with the required rapidly decreasing velocity distribution, the source rate of neutrals into the torus would seem to be inadequate. If the presence of the dense neutral cloud near Io limits ionization of all neutral species, a thick SO_2 atmosphere cannot be eliminated; however, velocity distributions previously estimated for this possibility[28] do not fall off rapidly enough with increasing velocity to produce the inward peak without invoking a source that is asymmetrical in longitude. (5) Although the above arguments suggest that the dominant source of ions in the hot torus is neutral sulphur, consistent with previous evidence from ion partitioning[26], an SO_2 or O source with a collision cascade velocity distribution would provide ions more widely distributed in radial distance and these ions may dominate the inner cool torus, whose composition need not be the same as that of the hot torus.

We thank F. Bagenal and J. T. Trauger for providing advance copies of their recent papers on the Io torus. We are grateful to P. R. Higbie for calling our attention to recent work on sputtering of sulphur and to W. H. Smyth for encouraging us to reconsider assumptions regarding the distribution of lifetimes. This work was partially supported by NASA under grant NSG-7295 and by the Jet Propulsion Laboratory under contract 955232.

Frequencies of solar 5-min oscillations can be used to determine directly the sound speed of the solar interior. The determination described here does not depend on a solar model, but relies only on a simple asymptotic description of the oscillations in terms of trapped acoustic waves.

SOLAR 5-min oscillations are acoustic waves that propagate in a waveguide beneath the surface of the Sun. For any particular wave, the guide is a spherical shell whose boundaries depend on the frequency and wavenumber of the wave. Upward directed waves are reflected just benath the photosphere, where the density scale height is comparable with the wavelength. Refraction of a wave initially propagating downwards deflects the path back towards the surface, at a point where the local horizontal component of the speed of the wave is equal to the sound speed.

The frequency of a wave that resonates in the waveguide depends on the variation of the sound speed with depth. The latter determines both the locations of the boundaries of the cavity within which the wave can propagate and the time it takes for the wave to traverse that cavity. By considering successively the frequencies of a sequence of modes that penetrate deeper and deeper, it is possible, at least in principle, to measure how the sound speed varies with depth.

Using an approximation to the observed dispersion relation presented in ref. 1 for modes with degrees in excess of 100, it has already been possible to estimate the sound speed in the upper half of the convection zone[2]. More recent observations[3,4] have isolated modes with degrees as low as unity, which sample almost the entire volume of the Sun. Therefore, we should now have sufficient data to infer the sound speed almost everywhere

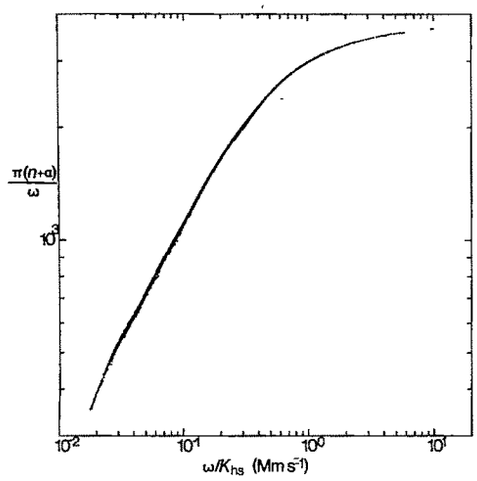

Fig. 1 Observed modes of solar 5-min oscillations collapsed according to the dispersion relation (1) with $\alpha = 1.58$. Units of ω and k_{hs} are s^{-1} and Mm^{-1}, respectively.

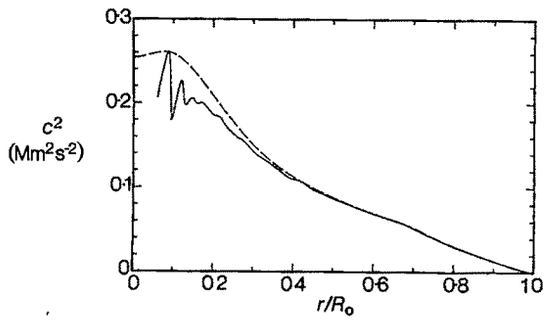

Fig. 2 Result of inverting computed eigenfrequencies of a solar model, using equation (13) to obtain an estimate c_m^2 (continuous line) of the square of the sound speed. Dashed line, square of the actual sound speed c^2 in the model. Units of speed, Mm s^{-1}.

Dispersion relation

A convenient form for analysing high-frequency p modes was introduced by Duvall[1]. He showed that if $\pi(n+\alpha)/\omega$ is plotted against ω/k_{hs}, where n is the order of the mode, ω is its frequency and k_{hs} is the horizontal component of its wave number vector in the photosphere, a value of the constant α could be found for which high-degree 5-min modes lie very close to a single curve. Thus,

$$\frac{\pi(n+\alpha)}{\omega} \simeq F(\omega/L) \tag{1}$$

where L is related to the degree l of the mode by

$$L^2 = l(l+1) = R_\odot^2 k_{hs}^2 \tag{2}$$

$R_\odot$ being the radius of the Sun. For the modes considered originally, $\alpha = 1.50$. This relation, with a somewhat different value of α, holds also for the eigenfrequencies of a solar model[5]. It is exact for a plane-parallel adiabatically stratified polytropic envelope[6,7] and deviations from it estimate an upper bound to the departure of the temperature gradient in the solar convection zone from its adiabatic value[2]. We now demonstrate that the relation is an asymptotic property of high-order acoustic modes in a spherical star, even when the stratification is not polytropic.

With respect to spherical polar co-ordinates (r, θ, ϕ) the vertical component v of velocity, say, of a linearized normal mode, has the functional form

$$v(r, \theta, \phi, t) = \mathrm{Re}[V(r)\, Y_l^m(\theta, \phi) e^{-i\omega t}], \tag{3}$$

where Y_l^m is a spherical harmonic of degree l and order m. Similar expressions hold for the perturbations in pressure and

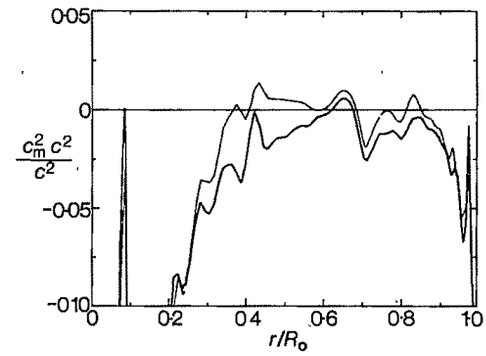

Fig. 3 Thick line, relative deviation $(c_m^2 - c^2)/c^2$ of the inferred squared sound speed c_m^2 shown in Fig. 2 from the actual value of c^2 in the theoretical model. Thin line, relative deviation from c^2 of the squared sound speed c_0^2 in Fig. 4 inferred from the solar data.

density. The amplitude function V satisfies a differential equation which admits, with appropriate boundary conditions, a discrete set of eigenfunctions that can be labelled with an integer n. The problem can be treated by standard asymptotic techniques when n is large[8–10]. The following simplified argument contains the essential physics, and to a good approximation yields the correct dispersion relation.

For modes with frequencies well in excess of the maximum buoyancy frequency in the Sun's interior (~0.5 mHz in standard theoretical solar models) the effect of buoyancy may be neglected. Furthermore, high-order modes produce a negligible perturbation to the gravitational potential. They may be characterized by a local wavenumber k whose vertical component $k_v(r)$ is much greater than the curvature and the inverse scale heights of the unperturbed structure of the Sun. The waves are therefore locally plane, satisfying

$$v(r, \theta, \phi, t) \propto e^{i(k\cdot r - \omega t)} \tag{4}$$

where r is the position vector and k and ω are related by the pure acoustic dispersion relation

$$\omega^2 = k^2 c^2 \equiv (k_v^2 + k_h^2) c^2 \tag{5}$$

with $k = |k|$. This simple relation is not valid close to the upper reflecting boundary of the cavity, where scale heights are comparable with k_v^{-1}. Nor indeed does it even predict the existence of that reflecting boundary. Where the relation is valid, however, it determines $k_v(r)$ according to

$$k_v^2 = k^2 - k_h^2 = \frac{\omega^2}{c^2} - \frac{L^2}{r^2} \tag{6}$$

Near the solar surface $\omega^2/c^2 \gg L^2/r^2$, unless L is very large, and $k_v^2 \gg k_h^2$. The waves propagate almost vertically, and the structure of the amplitude function V is essentially independent of the horizontal component k_h of the wave number vector. As r decreases, so does ω^2/c^2. Thus, according to equation (5), k_v^2 decreases with depth. The wave is refracted away from the vertical, and is eventually turned back at $r = r_t$, where

$$r_t^2/c^2(r_t) = L^2/\omega^2 \tag{7}$$

and propagation is locally horizontal.

From a comparison of the separated form of equation (3) with the local approximation in equation (4), it is evident that beneath the outer reflection point $V(r)$ is an oscillatory function where $r > r_t$. In particular, the difference in phase between the inner turning point $r = r_t$ and the outer reflection point $r = R_t$ is

$$\Delta\Psi = \int_{r_t}^{R_t} k_v \, dr \tag{8}$$

Had the mode been trapped between rigid surfaces the condition imposed by the waveguide would have been $\Delta\Psi = n\pi$, where n

is an integer. But the existence of evanescent regions above and below the cavity introduces an additional phase shift $\pi\alpha'$. Therefore, the dispersion relation is

$$\Delta\Psi = \int_{r_t}^{R_\odot} \left(\frac{\omega^2}{c^2} - \frac{L^2}{r^2}\right)^{1/2} \mathrm{d}r = \pi(n+\alpha') \tag{9}$$

Because the upper limit of integration is close to the surface of the Sun, we replace it by $R_\odot$ and absorb the small change in the integral into α', dropping the prime. The integral is now the product of ω and a function of ω/L alone, because, according to equation (7), r_t depends on ω and L only in the combination ω/L. Consequently the dispersion relation (9) becomes

$$F(w) \equiv \int_{r_t}^{R_\odot} \left(\frac{r^2}{c^2} - \frac{1}{w^2}\right)^{1/2} \frac{\mathrm{d}r}{r} = \frac{\pi(n+\alpha)}{\omega} \tag{10}$$

where $w = \omega/L$.

The phase shift introduced at the lower turning point is only weakly dependent on the structure of the solar model, because there the local dispersion relation (5) is a good approximation and the geometry of the deflection of the wave is adequately taken into account by the integrand in equation (10). Indeed, equation (9) may be derived directly from ray theory[11], in which $\Delta\Psi$ is expressed as an integral along a ray whose geometry is determined by equation (6).

For low-degree modes $r_t/R_\odot \ll 1$ and equation (10) may be approximated by

$$\omega \simeq \pi(n+\tfrac{1}{2}L+\alpha)\left(\int_0^{R_\odot} \frac{\mathrm{d}r}{c}\right)^{-1} \tag{11}$$

This can be compared with the dispersion relation for high-order acoustic modes of an isothermal gas confined in a rigid sphere, which is known exactly, and whose leading term is of the form in equation (11) with $L+2\alpha$ replaced by $l+1$. Thus, in this limit the form of equation (10) seems to be roughly correct, provided l is not too small.

To estimate the phase factor α it is necessary to account also for the phase shift on reflection at $r = R_t$. For this we consider the limit of high degree. In that case the modes are confined to the convection zone, which we approximate by an adiabatically stratified plane-parallel polytrope of index μ under constant gravity g. Then equation (10) becomes

$$\omega^2 = 2\mu^{-1}(n+\alpha)gk_{hs}, \tag{12}$$

which is identical to the exact dispersion relation under these conditions[6,7] if $\alpha = \mu/2$. Since conditions near $r = R_t$ are essentially independent of l, we deduce that this constant value of α is approximately valid for all l. Then equation (10) takes the form of equation (1). Moreover, if L were replaced by $l+\frac{1}{2}$, the approximation (11) would agree precisely with the leading term of previous asymptotic analyses[8,10] of low-degree p modes.

Observations

Measurements of $\omega(n, l)$ were made from two sets of Doppler observations using one or more of three different methods. The first data set[1] consists of a spectrum of prograde and retrograde sectoral and nearly sectoral modes with $105 \leq l \leq 892$. The resolution is ~ 10 in l and the uncertainty in the spatial scale is $\sim 0.5\%$. Frequencies were estimated by centroid analysis, and zonal-mode frequencies were deduced by averaging corresponding prograde and retrograde frequencies. The second data set[4] consists of a spectrum of zonal oscillations with $1 \leq l \leq 200$, with a resolution of ~ 3 in l and a scale uncertainty of $\sim 0.5\%$. For $l \leq 20$ individual modes could be isolated and identified, and their frequencies measured to ± 2 μHz. For $l > 20$ spline functions were fitted by eye to visual representations of sets of modes of like order n and used to determine the frequencies; we estimated that the frequencies determined in this way are correct

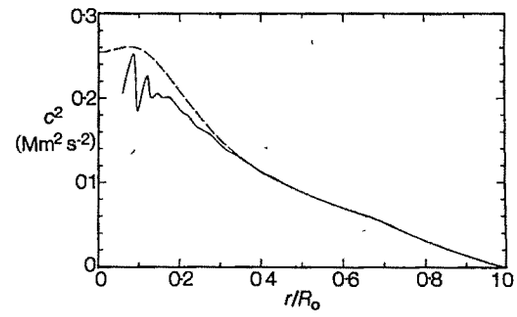

Fig. 4 Square of the interior sound speed c_0^2 in the Sun (continuous line) obtained by inverting the data in Fig. 1. The value of c^2 in solar model is included as a dashed line for comparison.

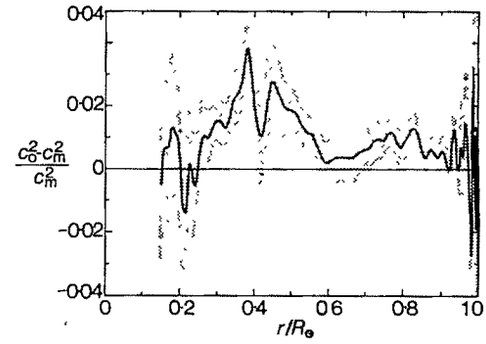

Fig. 5 Relative discrepancy $(c_0^2 - c_m^2)/c_m^2$ between the squared sound speeds in Figs 2 and 4 obtained by inverting corresponding oscillation frequencies of the Sun and the solar model. The shaded region lies within one standard deviation of that part of the error in the inferred values of c_0^2 resulting from random errors in the data It was computed from many theoretical realizations of the data obtained by adding random errors to the real solar data with the same variance as the error estimates that are indicated in the text.

to within ±10 μHz. When a mode was present in both data sets the average frequency was adopted in the subsequent analysis. A comparison of the original data sets revealed a systematic discrepancy that was larger than the estimated errors in either. The root of the discrepancy was traced to an error in the reduction of the high-degree data, which caused spatial scales to have been overestimated by 1%. Accordingly we increased the values of l in the original high-degree data set by 1%, although an increase of 1.4% would have minimized the discrepancy. In total, 2,820 modes were used, with lower turning points r_t in the range 0.06–0.994 $R_\odot$. Note that the quality of the estimates and the degree of smoothing changes at $l = 20$ and in the range 105–200.

The relation defined by equation (1) was fitted to the combined data, which are shown in Fig. 1. It was determined by choosing α such as to minimize the spread in the data, spread being measured by the sum of the squares of the altitudes of all triangles whose vertices are triplets of data points in Fig. 1 with consecutive values of ω/k_{hs}; for this purpose the base of a triangle is defined as the line joining the two points of a triplet with the extreme values of ω/k_{hs}. This yields $\alpha = 1.58$; other definitions of spread, such as the r.m.s. deviations of the data from an appropriately chosen smooth curve, gave similar results.

On the whole the scatter in the data decreases as ω/k_{hs} increases: those modes considered in ref. 1 having $\omega/k_{hs} \lesssim 0.1$ Mm s^{-1} have an r.m.s. deviation from a smooth curve of $\sim 0.4\%$, whereas the deviation is less than 0.1% when $\omega/k_{hs} > 1$ Mm s^{-1}. Theoretical eigenfrequencies of a solar model behave similarly. Therefore, it seems that much of the variation can be

attributed to the inaccuracy of our simple asymptotic analysis, which increases as l increases.

Inversion of dispersion relation

The first part of equation (10) can be inverted[11] to yield r as a function of c/r:

$$r = R_\odot \exp\left\{ -\frac{2}{\pi}\int_{c_s/R_\odot}^{c/r} [w^{-2}-(c/r)^{-2}]^{-1/2}\frac{\mathrm{d}F}{\mathrm{d}w}\,\mathrm{d}w \right\} \quad (13)$$

where c_s is the value of c at $r = R_\odot$. According to the second part of equation (10), the function F is equal to the observed quantity $\pi(n+\alpha)/\omega$. Consequently equation (13) can be used to determine $c(r)$ from the observations presented in Fig. 1 without any recourse to a solar model.

Given the simplified nature of the arguments leading to equation (10), the reliability of equation (13) may at first sight seem rather dubious. Therefore before using it to analyse the real solar data we tested it on a theoretical solar model. Adiabatic eigenfrequencies of the modes corresponding to those that had been observed on the Sun were computed, using the equilibrium solar Model 1 of ref. 12. These were fitted to the relation (1) in the manner described above, yielding $\alpha = 1.39$. A representation of the function F was then obtained by applying twice a 15-point running mean to the theoretical analogue of Fig. 1. The smoothing is necessary because deviations from the simple asymptotic law of equation (10) cause modes of different order to lie on somewhat different curves. The resulting estimate of $F(w)$ was extrapolated to $w = c_s/R_\odot$ with the power law Aw^a, with the coefficients $a = 1.035$ and $A = 1.70\times10^7$ (in c.g.s. units) chosen to match smoothly onto the lower end of the theoretical data. Its derivative was evaluated by centred second-order accuracy differencing of the smoothed representation of the data. Finally the expression on the right-hand side of equation (13) was evaluated using a difference scheme tailored to accommodate the square-root singularity in the integrand.

In Fig. 2 the square of the sound speed (c_m^2) inferred by this procedure is compared with the actual value of c^2 in the solar model. In a substantial region the result of the inversion is quite accurate. This is emphasized in Fig. 3, which shows the relative errors in the inferred values of c^2. For $r/R_\odot$ between 0.4 and 0.9, the error in c^2 is <2.5%.

In view of the breakdown of the assumptions of the asymptotic theory near the surface, the large error when $r > 0.9\ R_\odot$ is not surprising. The reason for the errors in the deep interior is less obvious, although it appears to arise in part from the fact that the inversion procedure is incremental, and can accumulate errors in the asymptotic analysis that occur nearer the surface.

Determination of solar sound speed

The inversion of the solar data in Fig. 1 was performed in exactly the same way as for the artificial data, except that the parameters definining the power law used to extrapolate F to the surface were $a = 0.846$, $A = 2.63\times10^6$. The results are presented in Figs 3–5.

The qualitative features of the inversions shown in Figs 2 and 4 are quite similar. A quantitative comparison is made in Fig. 5, in which the relative deviation of the square of the inferred solar sound speed (c_0^2) from that inferred by inverting the eigenfrequencies of the theoretical model (c_m^2) is plotted. In the region between 0.4 $R_\odot$ and 0.9 $R_\odot$, where the inversion is expected to work well, c_0^2 is within 3% of c_m^2. Furthermore, it is striking how the difference between c_0^2 and c_m^2 follows the errors in the inversion of the theoretical data, both of which are shown in Fig. 3. In particular, the behaviour is similar above 0.9 $R_\odot$ and below 0.4 $R_\odot$, where our inversion technique seems to fail. Systematic errors arising from inaccuracies in the simple asymptotic procedure are similar for the Sun and the solar model, suggesting that the error in Fig. 5 is substantially less than the discrepancies plotted in Fig. 3.

To test this hypothesis, we compared inversions of 5-min eigenfrequencies of two theoretical models of the Sun: Model A of Christensen-Dalsgaard *et al.*[13] and Model 1 (see ref. 12). The sound speeds in the two models differ substantially beneath the convection zone and thus provide a basis for assessing the significance of the deviations plotted in Fig. 5. Inversions were performed on 363 common modes whose frequencies lie in the range spanned by the solar observations. The relative difference between the squares of the sound speeds thus inferred is plotted in Fig. 6, together with the actual difference. Because relatively few modes were used, the errors in the inversions are rather greater than those illustrated in Fig. 3. However, they largely cancel in the difference plotted in Fig. 6, suggesting that except close to the solar surface and close to the centre, inversion errors contribute less to Fig. 5 than errors in the data. We conclude also from this comparison that the inversion technique is not sensitive to the detailed structure of the surface layers of the Sun. The sound speeds in Model A and Model 1 differ by up to 8% near the upper turning point R_t, and influence the frequencies of all 5-min modes whatever the value of l. However, as Fig. 6 demonstrates, those influences are successfully cancelled in that aspect of the function $F(w)$ that determines the sound speed at greater depths. This is achieved largely by absorbing the influence of the surface layers into the constant α, which takes different values for the two solar models.

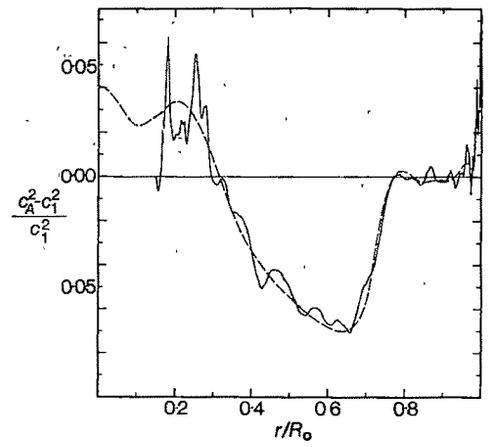

Fig. 6 Solid line is the relative difference $(c_A^2-c_1^2)/c_1^2$ between the inferred squared sound speeds c_1^2 and c_A^2 of Model 1 and Model A of the Sun obtained by inverting the frequencies of 363 5-min modes. Dashed line, actual relative difference.

We have also determined the effect of the spatial scale error in the original high-degree data by comparing inversions with and without the 1.01 scale factor imposed on l. At radii greater than 0.8 $R_\odot$ the inferred sound speeds differed by ~0.5%. At greater depths the difference decreased, and was <0.1% for $r < 0.6\ R_\odot$.

Discussion

It seems that in the region where we have succeeded in measuring $c(r)$ the differences between the solar values and those of the theoretical model are quite small. However, there is an indication that for r between 0.3 $R_\odot$ and 0.5 $R_\odot$ the sound speed in the Sun is generally somewhat greater than it is in the model. Deviations of the inferred sound speeds from a smooth curve are clearly similar in the two cases, and are partly dependent on mode selection. An earlier direct comparison between observed and calculated oscillation frequencies[14] suggested that there is an error in Model 1 somewhere between the turning points of the 5-min modes with $l = 20$ and with $l = 40$, which we find are located at $r/R_\odot \simeq 0.45$ and 0.70 respectively.

A change of curvature can clearly be seen in Figs 2 and 4 at $r \cong 0.7\ R_\odot$. This indicates the position of the base of the convection zone, which in the theoretical solar model is at $r = 0.71\ R_\odot$. In this respect the theory appears to mimic reality, and we deduce that the convection zone in the Sun is ~200 Mm deep. This value agrees with previous model-fitting calibrations by Berthomieu *et al.*[15] and by Shibahashi *et al.*[16], and is somewhat

greater than the value for the solar model preferred by Ulrich and Rhodes[17,18].

The relatively high sound speed deduced near $r = 0.4\ R_\odot$ deserves comment. A possible explanation is that the opacity used to construct the theoretical solar model is too low in the outer part of the radiative interior. An increase of ~20% in opacity at temperatures between $\sim 10^5$ and $\sim 4 \times 10^6$K, for example, would reduce the discrepancy to an insignificant level.

It has not yet been possible to determine the sound speed in the energy-generating core. This is particularly disappointing, for we had hoped to ascertain whether there had been substantial mixing in the chemically inhomogeneous layers. There are certainly grounds for believing, however, that the information is contained in the data[19].

It is of interest that the values of α obtained from the solar model and from the observations, namely 1.39 and 1.58, are significantly different, which indicates that errors in the theory of the surface layers have been made, either in the construction of the equilibrium model or in the oscillation calculation. This has also been found from comparing the observed and calculated frequencies directly[14]. A strength of the present approach is that it allows one to separate, in α, the effects of the surface layers where the physics of the oscillations is incompletely understood. The frequencies computed by Berthomieu *et al.*[15] and Shibahashi *et al.*[16] have $\alpha = 1.53$ and 1.51 respectively; the corresponding values of α computed from just those observed modes that are common with the calculations are 1.55 and 1.54. Thus, these models seem to represent the surface of the Sun more accurately. The frequencies published by Ulrich and Rhodes[18] have $\alpha = 1.40$, the corresponding value from the observations being 1.58.

Solar oscillation frequencies do not satisfy the relation in equation (1) exactly. The deviations, although small, are significant compared with the accuracy of the observations. Thus, we have not fully used the information contained in the data. To do so one must use either a higher-order asymptotic approach or a direct numerical calculation of the frequencies. In either case inversion would almost certainly be an iterative process. In general the result of such an analysis, like many a solution of a nonlinear problem, might depend on an initial guess of a model and may not necessarily be unique. On the other hand the JWKB asymptotic analysis used here does provide, in equation (13), a unique determination of the sound speed from the observed function F. The asymptotic analysis is valid if the scale of variation of the background state is much greater than all oscillation wavelengths considered, and that condition is indeed satisfied throughout most of the interior of any traditional theoretical model of the Sun. Therefore it is plausible that by using this asymptotic determination as an initial trial in a more accurate inversion, and imposing constraints of smoothness on the solution resulting from the iteration, a good model representing the large-scale structure of the Sun that satisfies the observed frequencies might be determined.

We thank S. Frandsen for useful conversations and R. K. Ulrich for helping us to improve the presentation.

Direct mutagenesis of Ha-*ras*-1 oncogenes by *N*-nitroso-*N*-methylurea during initiation of mammary carcinogenesis in rats

Helmut Zarbl, Saraswati Sukumar, Anne V. Arthur, Dionisio Martin-Zanca & Mariano Barbacid

Developmental Oncology Section, Basic Research Program, Frederick Cancer Research Facility, Frederick, Maryland 21701, USA

*Induction of mammary carcinomas in rats by a single exposure to a carcinogen during sexual development often involves malignant activation of the Ha-*ras*-1 locus. Each of the Ha-*ras*-1 oncogenes present in tumours induced by* N*-nitroso-*N*-methylurea, but not in those induced by 7,12-dimethylbenz(*a*)anthracene, became activated by the same G→A transition, the type of mutation induced by* N*-nitroso-*N*-methylurea. These results are consistent with the notion that Ha-*ras*-1 oncogenes are directly activated by the carcinogen during initiation of neoplasia.*

ELUCIDATION of the contribution of *ras* oncogene activation to the development of human neoplasia has been hampered by the unknown aetiology of most human cancers and the impossibility of experimental manipulations. Therefore, we have investigated animal tumour model systems that closely resemble human neoplasia. We have shown that transforming Ha-*ras*-1 genes can be reproducibly detected in mammary carcinomas induced in Buf/N rats by a single dose of *N*-nitroso-*N*-methylurea (NMU)[1]. Similar results have been obtained in other laboratories using other carcinogen-induced animal tumour systems[2-4] as well as with chemically transformed cell lines[5-7]. These carcinogen-activated *ras* oncogenes have the same type of activating mutations as those present in human tumours[1,8], thus validating these animal tumour systems as adequate models for studying the role of *ras* oncogene activation in human neoplasia.

Understanding the role that *ras* genes play in the multi-step process of carcinogenesis requires precise definition of the stage

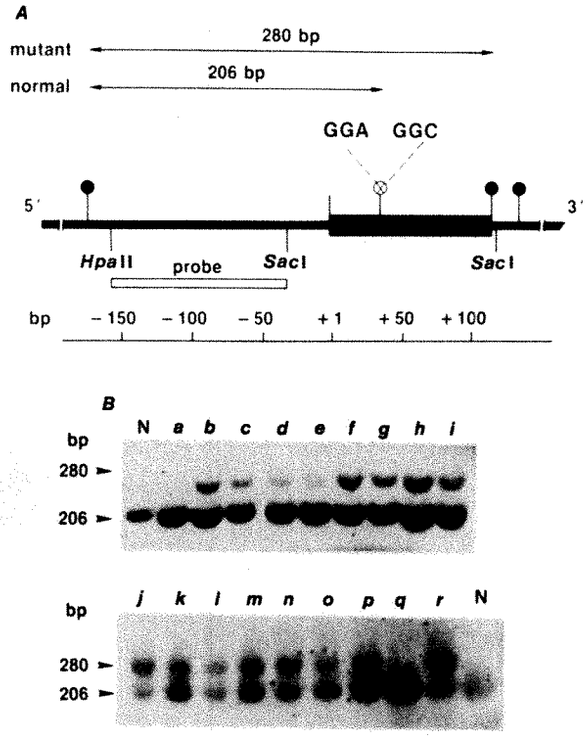

Fig. 1 *A*, Strategy for detection of *Mnl*I RFLPs created by mutations in codon 12 or 13 of the rat Ha-*ras*-1 locus. Wild-type *Mnl*I restriction sites (●) near the first exon (solid box, nucleotides +1 to +111) are indicated. The position of the polymorphic *Mnl*I site (GAGG, ⊗, nucleotides +35 to +38) relative to the sequences of the normal codon 12 (GGA) and codon 13 (GGC) is shown. The probe used is a 120-bp *Hpa*II to *Sac*I fragment (open box) comprising 5'-noncoding sequences derived from pNMU-1, a pBR322 derivative containing a transforming allele of the Ha-*ras*-1 locus[1] and allowing specific detection of this locus. Probes encompassing exon-coding sequences (for example, the 154-bp *Sac*I DNA fragment) detect an additional band, presumably derived from the Ha-*ras*-2 pseudogene, that interferes with detection of the *Mnl*I RFLPs. Arrows span the normal (206-bp) and polymorphic (280-bp) *Mnl*I restriction fragments detected by the 120-bp *Hpa*II/*Sac*I probe. ***B***, Use of *Mnl*I RFLPs to detect Ha-*ras* oncogenes in DNA isolated from NMU-induced rat mammary carcinomas: 40 μg of DNA isolated from normal breasts (N) and NMU-induced mammary carcinomas (*a*–*r*) were digested for 16 h with 40 U *Mnl*I using conditions recommended by the supplier (New England Biolabs). Digests were electrophoresed (18 h at 40 V) in horizontal 2.8% agarose gels (w/v) and blotted to either Zeta-Probe blotting membranes (Bio-Rad Laboratories) or nitrocellulose as described by Southern[23]. Membranes were hybridized under stringent conditions (50% formamide, 5×SSC, 42 °C) for 72 h to 10^7 c.p.m. ml^{-1} of ^{32}P-labelled probe obtained by nick-translation of the 120-bp *Hpa*II/*Sac*I DNA fragment described in *A*. Blots were exposed for 24 h to Kodak XAR-5 film at −70 °C in the presence of intensifier screens. Arrows indicate the positions of the normal (206-bp) and the polymorphic (208-bp) *Mnl*I restriction fragments. Co-electrophoresed ΦX174 DNA digested with *Hae*III served as size standards. Upper and lower panels represent two independent representative experiments.

at which they become activated. Recently, Balmain *et al.* have demonstrated the presence of transforming *ras* genes at the papilloma stage of 7,12-dimethylbenz(*a*)anthracene (DMBA)-induced skin carcinomas, suggesting that *ras* genes are activated early in tumour development[9]. Induction of rat mammary carcinomas by NMU does not proceed through identifiable preneoplastic stages[10]. We have taken advantage of two properties of this tumour system to investigate whether Ha-*ras*-1 oncogenes are involved in initiation of carcinogenesis. First, NMU is known to specifically (≥99%) induce G→A transitions (see refs 11, 12 for reviews). Here, we demonstrate that each of the Ha-*ras*-1 oncogenes present in NMU-induced mammary carcinomas became activated by G→A transitions in the second nucleotide of codon 12. No such mutations were observed in Ha-*ras*-1 oncogenes present in mammary carcinomas induced by DMBA, a carcinogen that does not induce specific G→A transitions[11]. These findings strongly implicate NMU as the agent directly responsible for the activation of Ha-*ras*-1 oncogenes. Second, the highly labile nature of NMU under physiological conditions has defined initiation of carcinogenesis as occurring within hours after administration of the single tumour-inducing dose of this carcinogen. Therefore, if NMU is responsible for the G→A mutations found in each Ha-*ras* oncogene, the process of oncogene activation must be concomitant with, and presumably contributing to, initiation of carcinogenesis.

Table 1 Malignant activation of the Ha-*ras*-1 locus in NMU-induced rat mammary carcinomas*

Strain	Mammary carcinomas Tested	Mammary carcinomas Ha-*ras*-1 oncogene	Normal breasts Tested†	Normal breasts Ha-*ras*-1 oncogene
Buf/N	38	31 (81%)	18	0
Sprague-Dawley	12	11 (92%)	8	0
Fischer 344	8	6 (75%)	ND	ND
Total	58	48 (83%)	26	0

* As determined by the *Mnl*I RFLP assay. Correspondence between *Mnl*I RFLPs and transforming activity was as high as 92% of tumour DNAs tested in more than one gene transfer assay. None of the normal breast DNAs was capable of inducing malignant transformation on transfection into NIH 3T3 cells.

† Includes four Buf/N and two Sprague-Dawley normal breasts obtained from tumour-bearing animals. ND, not done.

Mutagenesis in the Ha-*ras*-1 locus

We have previously reported the presence of transforming Ha-*ras*-1 genes in nine mammary tumours of inbred Buf/N rats induced by NMU[1]. One of these oncogenes was molecularly cloned and its activating mutation identified as a G→A transition in the second nucleotide of codon 12 (ref. 1). This mutation eliminates a GAGG sequence that is specifically recognized by the restriction endonuclease *Mnl*I, thus creating a diagnostic restriction fragment length polymorphism (RFLP). The first exon of the normal Ha-*ras*-1 allele is located in two *Mnl*I DNA fragments of 206 and 74 base pairs (bp) (Fig. 1*A*). Elimination of the *Mnl*I cleavage site generates a single 280-bp *Mnl*I DNA fragment. Wild-type (206 bp) and polymorphic (280 bp) DNA fragments were identified by Southern blot analysis using the 120-bp *Hpa*II/*Sac*I DNA fragment depicted in Fig. 1*A* as a probe.

Thirty-one of 38 DNAs isolated from NMU-induced tumours in Buf/N rats exhibited the diagnostic *Mnl*I RFLP (Fig. 1*B*, Table 1). In addition to the 280-bp polymorphic fragment, each tumour DNA exhibited the normal 206-bp *Mnl*I DNA fragment indicative of heterozygosity at this locus (Fig. 1*B*). Similar results were obtained with random-bred Sprague-Dawley (11 out of 12) and Fischer 344 (6 out of 8) rats, indicating the general validity of these observations. In total, 83% (48 out of 58) of all NMU-induced tumours tested scored as positive in the *Mnl*I/RFLP assay. Of these 48 tumour DNAs, 36 (75%) induced malignant transformation of NIH 3T3 mouse cells in gene transfer experiments, verifying that transfection is a reliable assay for the detection of *ras* oncogenes.

None of 20 normal breast DNAs obtained from 14 Buf/N and 6 Sprague-Dawley rats exhibited the *Mnl*I RFLP (Table 1). Moreover, the 10 tumour DNAs that did not exhibit the *Mnl*I polymorphism failed to transform NIH 3T3 cells even when repeatedly tested in gene transfer experiments. These findings indicate that malignant activation of Ha-*ras*-1 oncogenes in NMU-induced mammary carcinomas is the result of mutations specifically localized in a region no larger than four nucleotides.

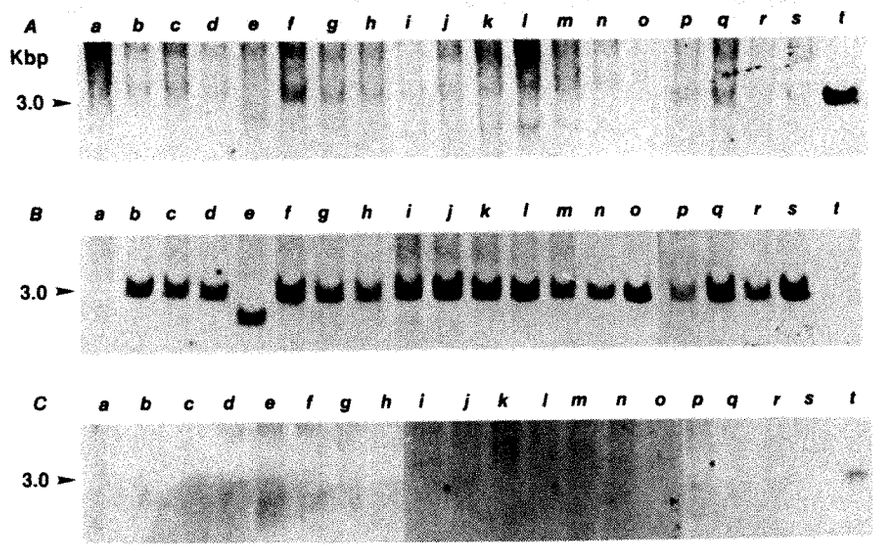

Fig. 2 Use of synthetic oligonucleotide probes to determine the point mutations responsible for malignant activation of the Ha-*ras*-1 locus in NMU-induced rat mammary carcinomas. *A*, Hybridization with probe Ha19-G^{35} (5′-TGGGCGCTGGAGGCGTGGG-3′), which recognizes nucleotides +26 to +44 of the normal Ha-*ras*-1 locus. *B*, Hybridization with probe Ha19-A^{35} (5′-TGGGCGCTGAAGGCGTGGG-3′), which detects Ha-*ras*-1 oncogenes activated by G→A transitions at nucleotide +35. *C*, Hybridization with probe Ha19-T^{35} (5′-TGGGCGCTGTAGGCGTGGG-3′), which detects Ha-*ras*-1 oncogenes activated by G→T transversions at nucleotide +35. *a*, DNAs isolated from NIH 3T3 cells; *b–s*, representative NIH 3T3 transformants derived from NMU-induced mammary carcinomas; *t*, NIH 3T3 cells co-transfected with the normal Ha-*ras*-1 gene and pSV2-neo[14] and selected for growth in the presence of G418. Arrowheads indicate the expected 3.0-kilobase (kb) *Hin*dIII DNA fragment of Ha-*ras*-1 containing all coding sequences except the first 12 nucleotides[1]. Abnormal migration is occasionally seen because the 3′ *Hin*dIII cleavage site maps outside the Ha-*ras*-1 locus and is occasionally lost during transfection. In control experiments, none of these DNAs hybridized to pBR322 or λ phage vector sequences. Co-electrophoresed DNA fragments of *Hin*dIII-cleaved λ*c*1857 DNA served as size standards. Results were compiled from two independent representative experiments.

Methods. 30 μg of each DNA was digested with 240 U of *Hin*dIII using conditions recommended by the supplier (New England Biolabs). Digests were electrophoresed (12 h at 50 V) in horizontal agarose gels (0.7% w/v) which were subsequently prepared for hybridization as described previously by Kidd *et al.*[24]. Dried gels were prehybridized for 1 h in hybridization buffer[24] containing 500 μg ml^{-1} of sonicated herring sperm DNA. Gels were subsequently hybridized for 18 h at 64 °C with individual oligonucleotide probes at a concentration of 5 ng ml^{-1} (2.5×10^9 c.p.m. μg^{-1}) in hybridization buffer containing 100 μg ml^{-1} sonicated herring sperm DNA. Hybridized gels were then washed with constant agitation as follows: four changes (300 ml) of 6×SSC for 15 min each at room temperature, 400 ml of 6×SSC for 30 min at room temperature; 500 ml of 6×SSC at 66 °C was then poured onto the gel and allowed to cool to room temperature (30 min). Finally, the gel was rinsed with 200 ml of 6×SSC at room temperature, dried and exposed to Kodak XAR-5 film for 18 h at −70 °C in the presence of intensifier screens. Labelling of oligonucleotide probes was performed under conditions allowing quantitative phosphorylation of 5′ termini with polynucleotide kinase. Reactions (300 μl) contained 0.01 nmol of individual nonadecamers, 1 nmol [γ-^{32}P]ATP (7,000 Ci mol^{-1}; NEN), 60 mM Tris-HCl (*p*H 7.8), 15 mM 2-mercaptoethanol, 10 mM $MgCl_2$ and 60 U T_4 polynucleotide kinase (New England Biolabs). Incubations were for 30 min at 37 °C and reactions were stopped by making mixtures 20 mM with respect to EDTA (*p*H 7.5). Labelled oligonucleotides were separated from unincorporated [γ-^{32}P]ATP by ion-exchange chromatography on Elutip-d columns (Schleicher & Schuell) according to the manufacturer's protocol. ^{32}P-oligonucleotides were eluted with 0.5 ml of 1 M NaCl, 20 mM Tris-HCl (*p*H 7.5), 1 mM EDTA and added directly to hybridization mixtures.

G^{35}→A mutations

We next examined whether the diagnostic *Mnl*I RFLPs detected in each of the Ha-*ras*-1 oncogenes present in NMU-induced mammary carcinomas were always the consequence of G→A mutations, which would implicate the mutagenic activity of NMU in the generation of these oncogenes. We used oligonucleotide probes to detect specific point mutations in genomic DNA[13]. We synthesized nonadecamers capable of identifying substitutions in position 35, the only nucleotide of the *Mnl*I cleavage site that can alter the coding properties of the critical codon 12 of the Ha-*ras*-1 gene. Oligomers included Ha19-G^{35} (5′-TGGGCGCTGG*AGGCGTGGG-3′, where the underlined nucleotides define the diagnostic *Mnl*I cleavage site present in wild-type DNA and G* is the deoxyguanosine residue at position 35), Ha19-A^{35} and Ha19-T^{35}. Ha19-A^{35} and Ha19T^{35} possessed the same sequence as Ha19-G^{35} except that the residue corresponding to position 35 (G* in Ha^{19}-G^{35}) was substituted by either a deoxyadenosine in Ha19-A^{35} or a thymidine in Ha19-T^{35}. The corresponding Ha19-C^{35} oligonucleotide was not synthesized because G^{35}→C transversions would have created a polymorphic *Pst*I cleavage site that was not detected in any of the tumours tested (data not shown).

Oligonucleotides probes were hybridized to *Hin*dIII-cleaved DNAs isolated from representative NIH 3T3 transformants obtained from each of 36 NMU-induced mammary carcinomas that scored positive in gene transfer experiments. NIH 3T3 transformants were selected because they usually contain amplified oncogene sequences and lack the normal Ha-*ras*-1 rat allele. Results of representative experiments are given in Fig. 1. At the discriminating temperature, each of the 36 NIH 3T3 transformants tested hybridized to Ha19-A^{35} but not to Ha19-G^{35} or Ha19-T^{35}, indicating that their transforming Ha-*ras*-1 oncogenes carried identical G→A transitions in position 35. DNA isolated from NIH 3T3 cells containing a normal Ha-*ras*-1 proto-oncogene (which was co-transfected with pSV2-neo[14])

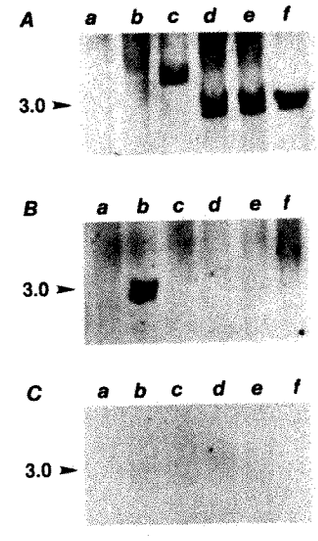

Fig. 3 Absence of point mutations in codon 12 of Ha-*ras*-1 oncogenes present in mammary carcinomas induced by DMBA. *A*, Ha19-G^{35} detects Ha-*ras*-1 genes with a normal codon 12 (G at position +35); *B*, Ha19-A^{35} detects G→A transitions in position +35; *C*, Ha19-T^{35} detects G→T transversions in position +35. Arrowheads indicate the expected position of the 3.0-kb *Hin*dIII fragment as deduced from co-electrophoresed DNA fragments of *Hin*dIII-cleaved λ*c*1857 DNA. *a*, DNAs isolated from NIH 3T3 cells; *b*, NIH 3T3 transformant derived from an NMU-induced mammary carcinoma; *c–e*, representative NIH 3T3 transformants derived from DMBA-induced mammary carcinomas; *f*, NIH 3T3 cells co-transfected with the normal Ha-*ras*-1 gene and pSV2-neo[14] and selected for growth in the presence of G418. These DNAs were digested with *Hin*dIII and electrophoresed in 0.7% (w/v) agarose gels. Dried gels were hybridized to each of the three nonadecamer probes using the same conditions as described in Fig. 2 legend.

Table 2 Malignant activation of the Ha-*ras*-1 locus in NMU- and DMBA-induced rat mammary carcinomas

Carcinogen	Oncogene detection*	Ha-*ras*-1 oncogene	$G^{35} \rightarrow A^{35}$ mutation
NMU	48/58 (82%)	48/48 (100%)	36/36 (100%)
DMBA	3/14 (21%)	3/3 (100%)	0/3 (0%)

These results demonstrate that the same point mutation is responsible for malignant activation in NMU- but not in DMBA-induced rat mammary carcinomas

* Results of NMU-induced tumours include *Mnl*I RFLP and gene transfer assays.

hybridized to Ha19-G^{35} but not to Ha19-A^{35} or Ha19-T^{35}oligonucleotide probes (Fig. 2). These results demonstrate that each of the Ha-*ras*-1 oncogenes present in NMU-induced mammary carcinomas became activated by the same mutation, a G→A transition in the second nucleotide of the critical 12th codon.

Ha-*ras*-1 genes in DMBA-induced tumours

The striking specificity of our findings suggests that the activating $G^{35} \rightarrow A$ mutations are the direct consequence of the mutagenic activity of NMU. However, we also considered the possibility that the presence of p21 proteins carrying glutamic acid residues in position 12 confers a selective growth advantage on the neoplastic mammary cells. To resolve this question we examined the mutations responsible for the activation of Ha-*ras*-1 oncogenes in mammary carcinomas induced by DMBA. DMBA, unlike NMU, forms large adducts with deoxyguanosine and deoxyadenosine residues that lead to excision repair, thus generating point mutations of undefined specificity[11]. Representative NIH 3T3 transformants derived from each of the three DMBA-induced mammary carcinomas known to contain a transforming Ha-*ras*-1 oncogene efficiently hybridized to the Ha19-G^{35} probe but not to the Ha19-A^{35} or Ha19-T^{35} probes (Fig. 3). These results indicate that DMBA-induced Ha-*ras*-1 oncogenes do not contain point mutations in either the 12th or adjacent codons. In agreement with these observations, none of these oncogenes exhibit the polymorphic *Mnl*I RFLP (data not shown).

Activation of Ha-*ras*-1 oncogenes in DMBA-induced tumours probably involves mutations in codon 61 (refs 15, 16). Although we have not defined the nature of such mutations, note that codon 61 of the rat Ha-*ras*-1 proto-oncogene is CAA[1,17]. G→A transitions cannot occur in this codon because they will result in the generation of a terminator codon, TAA. Whatever the specific nature of DMBA-induced mutations, our results argue strongly against the possibility that the specific $G^{35} \rightarrow A$ mutations of NMU-induced Ha-*ras*-1 oncogenes are the result of a positive growth selection process or a unique DNA repair system present in mammary cells. Instead, the results indicate that malignant activation of the Ha-*ras*-1 locus in NMU-induced mammary carcinomas must be the direct result of the mutagenic effect of NMU.

Biological implications

Induction of mammary carcinomas in rats by an injection of a single dose of NMU is one of the animal tumour systems most amenable to molecular analysis[1]. Because of the specific mutagenic properties of NMU (G→A transitions) it has been possible to examine whether oncogenes can be the target of chemical carcinogens. Our results demonstrate that each of 36 NMU-induced Ha-*ras*-1 oncogenes carried the same activating $G^{35} \rightarrow A$ mutation (Table 2). These findings strongly support the concept that these mutations are caused by NMU-directed methylation of the O^5 position of the second deoxyguanosine (G^{35}) in the critical codon 12. If so, our observations represent the first identification of an oncogene as a target for a chemical carcinogen. Alternative explanations for the observed mutational specificity, such as specific G→A repair mechanisms in mammalian cells or frequent G→A substitutions during tumour development, are unlikely in view of our control studies with DMBA-induced Ha-*ras*-1 oncogenes (Table 2). Moreover, Guerrero *et al.* have recently shown that Ki-*ras* oncogenes reproducibly activated in mouse lymphomas induced by γ-radiation exhibit diverse activating mutations[8] as expected from the type of DNA lesions induced by this carcinogen[11].

Our findings have further biological implications. Efficient induction of mammary carcinomas can be readily achieved by a single dose of NMU[1,18]. Because of the highly labile nature of NMU, its mutagenic effect must occur within hours following its administration. Therefore, our results imply that malignant activation of the Ha-*ras*-1 locus by NMU-induced G→A mutations must be concomitant with the initiation of the carcinogenic process.

Several laboratories have shown that *ras* oncogenes cannot transform normal (primary) rodent embryo cells unless they acquire the capability of self-proliferation either spontaneously (that is, NIH 3T3 cells), by carcinogen treatment[19] or by transfection of other oncogenes such as c-*myc*[20], adenovirus E1a[21] or even Ha-*ras*[22] when linked to strong transcriptional enhancers. It might be postulated that initiation of carcinogenesis by NMU requires the concomitant activation of two or more cooperating oncogenes, only one of which, Ha-*ras*-1, can be detected in gene transfer assays. But it is equally plausible that hormone-dependent proliferation, a normal physiological process required for tumour induction and (in some cases) progression, might provide conditions that are adequate for the phenotypic expression of the NMU-activated Ha-*ras*-1 oncogenes.

We thank Drs Steve Hughes, William Lijinsky and George Vande Woude for comments and for critically reading the manuscript. We also thank Dr P. Gullino for the DMBA-induced mammary tumours. H.Z. is the recipient of a Postdoctoral Fellowship from Fonds de la Recherche en Santé du Québec, Québec, Canada. Research sponsored by the National Cancer Institute, DHHS, under contract N01-CO-23909 with Litton Bionetics, Inc.

Note added in proof: We have now identified $G^{35} \rightarrow A$ transitions in each of the H-*ras*-1 oncogenes present in the 48 NMU-induced mammary tumours used in this study. In addition, we have localized the activating mutation of the three DMBA-induced H-*ras*-1 oncogenes in the two deoxyadenosine residues of codon 61 (CAA).

Galactic mergers, starburst galaxies, quasar activity and massive binary black holes

C. Martin Gaskell

Astronomy Department, University of Texas, Austin, Texas 787172, USA

Many quasar-like objects show evidence for massive binary black holes[1]. The recent discovery[2] of a massive ($5\times10^6\ M_\odot$) object in the centre of the local group dwarf elliptical M 32 greatly raises the probability of forming such binaries through galactic mergers. Here I argue that the enhancement of all kinds of activity (quasar-like activity and star formation) in galaxies with companions is not so much a consequence of tidal interaction between the massive galaxies as the result of collisions with their dwarf satellites.

Recent studies have shown that interactions between galaxies play a role in stimulating nuclear activity[3]. Imaging studies of high luminosity quasars[4,5] reveal that more than 30% have normal companion galaxies very close to them (here I use the term 'normal' galaxy to refer to any galaxy with a mass of $10^{11}M_0$ or more and refer to companion galaxies with masses much less than this as 'satellite' galaxies). Surveys of normal galaxies show that close pairs of galaxies are more likely to show activity characterised by optical emission lines[6,7] and radio emission[8] than are isolated galaxies. These results support the idea that most or all normal sized galaxies have massive black holes in their centres[3]. For simplicity I will assume that all normal galaxies have massive ($\geq10^6\ M_\odot$) black holes in their centres (it makes little difference here if the percentage is actually as low as 20%, as could be the case). The enhanced nuclear activity in pairs of galaxies would seem also to support an idea proposed by Toomre and Toomre[9] that close encounters may drive gas into the nuclear regions of a galaxy and either feed the central black hole directly or lead to a burst of star formation within the inner nuclear disc[7] which could indirectly increase the fuel supply rate. In addition to the enhanced nuclear activity close pairs of galaxies have enhanced star formation rates (as evidenced by far infrared emission[10]).

There are two problems with the Toomre and Toomre scenario. First, although a close pair of galaxies (with a projected distance of ~3 Holmberg diameters or less) is more likely to be active (as a Seyfert or radio galaxy), the majority of such galaxies (>75%) do not show nuclear activity. The mechanism is therefore less than 100% efficient or there is some other factor involved. The second problem is that although close encounters can wreak havoc on the outer parts of galaxies, the motions of the stars and gas in the tightly gravitationally bound cores are unaffected.

The solution I propose to these problems is that it is not actually the detected neighburing galaxy that is triggering quasar activity (or star formation) but instead a direct collision with one of the several dwarf satellite galaxies in the system. There is then no need to invoke some subtle action at a distance (tidal?) effect. Although the statistics of these dwarf satellite galaxies are poorly known, since they are difficult to detect beyond our local group, there are probably several (2–10) associated with each normal galaxy like our own[11]. I will here use the term 'dwarf' galaxy to refer to ellipticals and irregulars with absolute magnitudes in the approximate range $-14>M_V>-18$ (and hence ignore systems such as the Draco dwarf spheroidal). In our own local group there are two magellanic irregulars associated with our galaxy and four dwarf ellipticals associated with M31 in Andromeda.

In the scenario I propose here the statistical enhancement of quasar-like activity in close pairs of galaxies arises because of the increased probability of a merger with an unseen dwarf satellite galaxy when two normal galaxies are close. A 10^8–10^{10} $M_\odot$ dwarf galaxy near a Seyfert is hard to detect with present techniques and the only sign of a collision or merger might be the enhanced quasar-like activity and/or a burst of star formation (perhaps creating a 'starburst' galaxy). I suggest that the type of activity produced is a function of the Hubble type of the colliding satellite galaxy and the impact parameter. The amount of visible damage is also obviously going to depend on the mass of the dwarf. If a magellanic irregular galaxy hits a spiral galaxy anywhere the most probable result is a burst of star formation. If it hits the nucleus the resulting gas input and star formation could result in quasar-like activity as well. On the other hand the impact of a small elliptical galaxy, devoid of dust and gas, on the outer regions of a spiral galaxy will probably be much less spectacular. Perhaps only a distortion of the disc and spiral arms of the galaxy will occur (a dwarf elliptical satellite has typically 1% of the mass of a normal spiral and that the stars themselves do not collide).

The collision of a dwarf elliptical with a nucleus containing a dormant (or almost dormant) black hole will be more interesting. Unlike magellanic irregulars, the majority of dwarf ellipticals have strong central mass concentrations[12]. Tonry has produced powerful evidence that the 'spike' in the centre of M 32 is caused by a $5\times10^6\ M_\odot$ black hole. It would seem likely that the spikes in the luminosity profiles of other dwarf ellipticals are due to similar black holes. In a collision, if the impact parameter is small enough, the nucleus of the dwarf elliptical will be captured by the nucleus of the larger galaxy. The two black holes will go into orbit[1,13]. The distribution of stars in phase-space around each black hole will be severely perturbed, resulting in an increased fuelling of one or both black holes. I have proposed elsewhere[1] that the displaced broad-line peaks seen in many objects are the result of such orbital motion and argued that the velocities seen are consistent with the evolution of supermassive binary black holes. The discovery of a black hole in a dwarf elliptical now makes the creation of such binaries much more probable since there are an order of magnitude more dwarf galaxies than normal galaxies and the probability of mergers is correspondingly greater.

Detailed computer simulations of mergers of galaxies of all Hubble types and sizes taking into account both stars and gas need to be undertaken, as collisions of normal galaxies with dwarf satellite galaxies offer a likely explanation of both starburst galaxies and quasar-like activity. The Hubble Space Telescope could well reveal the results of the collisions when high spatial resolution studies of active galaxies are made.

I am grateful to Antoinette de Vaucouleurs, Gérard de Vaucouleurs and Derek Wills for useful comments. Partial financial support from McDonald Observatory is gratefully acknowledged.

Occurrences of diamondiferous kimberlites in southern Africa are concentrated within the boundaries of the Kaapvaal craton where crustal rocks are as old as 3,500 Myr (ref. 1). Garnet inclusions from diamonds that erupted in the Finsch kimberlite and kimberlites of the Kimberley group, situated in the southern part of the craton, have Rb/Sr and Sm/Nd model ages of 3,200–3,300 Myr (ref. 2). These kimberlites were erupted ~100 Myr ago[3,4]; thus the diamonds are xenocrysts. The localization of diamond-bearing kimberlites in the craton and the eruption of Archaean diamonds in late Cretaceous time are evidence that these diamonds crystallized and were immobilized in a root extending to depths of 150–200 km. Our applications of thermobarometry to silicate inclusions in the diamonds suggest that ambient temperatures at those depths 3,000 Myr ago were 900–1,200 °C, similar to the range predicted from present-day heat flow[5].

Monomineralic inclusions of olivine, garnet and pyroxenes are common in diamonds, and separate inclusions of two minerals in a single diamond have been found in many specimens[6]. Equilibration temperatures for these inclusion sets can be estimated by application of the same methods of geothermometry that have been widely used for garnet peridotite xenoliths[7–9], but it is important to recognize a marked difference in the circumstances of equilibration of the xenoliths and the inclusions.

Mineral grains in mantle rocks erupted as xenoliths were in contact with each other (and possibly with pore fluids) and had the potential for chemical exchange at high temperature until the time of eruption. Mineral grains that are included and isolated in diamonds, however, have chemical compositions that were fixed at the time of crystallization of the diamonds. The isolation of diamond inclusions is manifest in the marked differences in Nd and Sr isotope ratios obtained for garnet inclusions in diamonds and similar garnets from disaggregated mantle rocks found in kimberlite concentrates[2].

A crystallization history that is different from that of the inclusions has been experienced by three garnet lherzolite xenoliths from southern Africa that have diamond intergrown with primary silicate grains[10,11]. These and numerous non-diamondiferous, low-temperature garnet peridotites from many kimberlite pipes have estimated temperatures and depths of origin that approximate a continental shield geotherm[7,12]. The blocking temperatures for exchange equilibria used for peridotite thermometry have been estimated to be 700 °C (ref. 13) and 900 °C (ref. 14) on the basis of observed compositional profiles and experimental diffusion data. All three diamond-bearing lherzolites have equilibration temperatures in the range 1,050–1,150 °C (refs 7, 10). The least favourable estimate for the rate of equilibration at such temperatures[14] makes it probable that these peridotites reached chemical equilibrium within 10–100 Myr of the time of eruption. Thus, the times at which compositional relations were established for Archaean diamond inclusions and for the diamondiferous peridotite xenoliths erupted 100 Myr ago are believed to differ by ~3,000 Myr.

The assumption that mineral grains forming separate inclusions in a single diamond were in chemical equilibrium at the time of crystallization is supported by the fact that multiple inclusions of one mineral have the same composition[15]. The relative homogeneity of xenolith minerals[16] and the fact that coexisting olivine, garnet and pyroxene have systematic partition relations for most major and minor elements[7] are strong evidence of chemical equilibration for these rocks.

Diamond crystallization temperatures provide an upper limit for ambient temperatures at depth in the mantle at the times of diamond crystallization. The nature of the crystallization events in which natural diamonds have formed is not known; they may have been igneous or metasomatic or both. Nevertheless, these events can only have raised surrounding temperatures to values that were locally above ambient. The lower range of crystallization temperatures estimated for diamond inclusions is thus an approximation for ambient temperatures.

Comparative evaluation of element exchange reactions that can be used as thermometers for garnet-bearing, Mg-rich mineral assemblages has shown that application of the diopside–solvus method yields superior accuracy and precision[7]. The solvus cannot, however, be used for eclogitic assemblages or for diopside-free rocks and diamond inclusion sets. With such assemblages, comparable results can be obtained with Mg/Fe partition reactions, although in application to peridotites these Mg/Fe thermometers produce a scatter in estimated equilibration temperatures that is probably caused by the presence of small but unknown amounts of iron (III) (ref.7).

Two Mg/Fe partition relations that have wide applicability in the study of diamond inclusions are clinopyroxene–garnet[17] and olivine–garnet[18]. The effects on both of pressure and of the non-ideal substitution of Ca in garnet have been evaluated. The precision that can be obtained with the olivine–garnet thermometer has been estimated to be ±50 °C for favourable conditions of temperature (<1,300 °C) and composition[18], and the uncertainty associated with the garnet–diopside experimental data is a comparable value of ±5% of the temperature[17].

Peridotitic garnets included in diamonds are commonly Cr-rich with Cr_2O_3 contents ranging up to 15 wt%. The effects of this solid solution on the garnet–olivine (Mg/Fe) thermometer have not yet been evaluated. Garnets in low-temperature lherzolite xenoliths have an overlapping range for Cr_2O_3 of 2–9 wt%, and for most of these rocks, temperatures estimated with the garnet–olivine thermometer agree with those based on the diopside solvus within 100 °C (ref. 19). There is no discernible relationship between estimated equilibration temperature and Cr content of garnet for the peridotite and diamond-inclusion assemblages. Hence, an effect of Cr solid solution on the garnet–olivine thermometer seems unlikely to be important.

Analyses for 31 olivine–garnet inclusion pairs from Finsch diamonds show that 29 of the garnets are low-Ca pyropes[15], typical of the most common peridotitic garnets found included in diamonds. These are different specimens but are similar in composition to the garnet inclusions for which Archaean ages were obtained[2]. Crystallization temperatures estimated for these Finsch olivine–garnet inclusion sets have the range 900–1,300 °C at an assumed pressure of 50 kbar, within the diamond stability field[19]. Only two of the pairs, however, have crystallization temperatures above 1,150 °C. Most, with temperatures of 900–1,150 °C, are believed to best reflect crystallization in near ambient conditions.

The olivine–garnet (Fe/Mg) thermometer has a small pressure sensitivity, ~5 °C $kbar^{-1}$. Estimates for the crystallization temperatures of the 29 lower-temperature inclusion pairs thus plot in a pressure–temperature (P–T) band 250 °C wide with a slope of 5 °C $kbar^{-1}$ lying in the diamond stability field (Fig. 1). One diamond inclusion set from Finsch contains the assemblage enstatite–olivine–garnet[20], and estimation of equilibration pressure using the Al content of the enstatite, as well as temperature using the olivine–garnet thermometer, can be made for this assemblage. A point for the three-phase set plots in the diamond stability field and within the P–T band established for the olivine–garnet pairs. Estimates for the crystallization temperatures and depths of these inclusions plot close to a shield geotherm calculated for a heat flow of 40 mW m^{-2} (ref. 5).

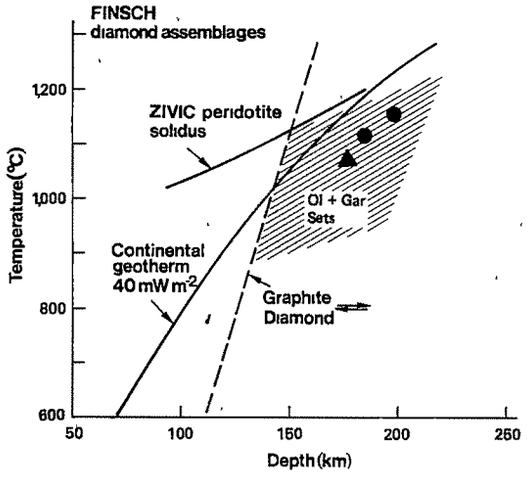

Fig. 1 Estimated equilibration conditions for diamondiferous assemblages from the Finsch kimberlite compared with the diamond-graphite equilibrium curve[35], a continental geotherm calculated for a heat flow of 40 mW m^{-2} (ref. 5), and the solidus for peridotite in the presence of H_2O and CO_2 (ZIVIC)[29]. The band defined by ruled lines is for temperature estimates made by the (Fe/Mg) olivine-garnet method[18], for 29 pairs of olivine and garnet inclusions. ▲, Olivine-garnet-orthopyroxene assemblage in a single diamond[20] for which temperature was estimated by the (Fe/Mg) olivine-garnet thermometer and pressure was obtained by the Al-enstatite method[7,36]. ●, Diamondiferous lherzolite xenoliths[10]; temperatures for these were estimated from the diopside solvus[37], and pressures, from the alumina content of enstatite[7,36].

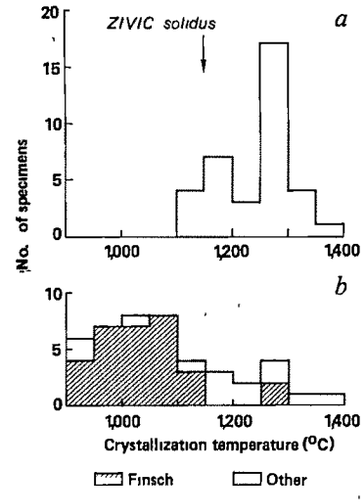

Fig. 2 Equilibration temperatures for sets of diamond inclusions of both eclogitic (*a*) and peridotitic (*b*) parageneses estimated for a pressure of 50 kbar (160 km). Eclogitic inclusions are from diamonds erupted in the Roberts Victor, Orapa and Premier kimberlites. Peridotitic inclusions are from diamonds originating at Finsch, Jagersfontein, Koffiefontein, Roberts Victor, Premier and an unknown locality. Temperatures for eclogitic inclusions were estimated with the garnet-clinopyroxene (Fe/Mg) thermometer[17]. Those for peridotitic inclusions were estimated primarily with the olivine-garnet (Fe/Mg) relation[18], but the diopside solvus[37] and garnet-clinopyroxene (Fe/Mg) thermometer[17] were also used.

Equilibration conditions estimated for two diamond-bearing garnet lherzolite xenoliths from the Finsch pipe also plot in the diamond stability field in proximity to the inclusion data (Fig. 1). The fact that the equilibration conditions for most of the inclusions and the lherzolites are similar and concordant with the shield geotherm suggests that these P-T conditions were near ambient and that they have changed little in ~3,000 Myr.

Whether there are age differences either for diamonds of eclogitic and peridotitic affinities or related to their location in the Kaapvaal craton is not yet established, but all data available indicate Precambrian ages for diamond crystallization. Diamonds with garnet inclusions from the Finsch and Kimberley pipes dated at 3,200–3,300 Myr (ref. 2) have a peridotite paragenesis. Diamonds with both eclogitic and peridotitic affinities are present in the Premier kimberlite, and sulphide inclusions in Premier diamonds have yielded a model Pb age of 1,200 Myr (ref. 21); the paragenesis of the dated specimens, however, is unknown. Isotope analyses for Pb in clinopyroxenes from eclogite xenoliths from the Roberts Victor kimberlite define an apparent age of 2,500 Myr (ref. 21), whereas Sm/Nd and Rb/Sr determinations for other Roberts Victor samples indicate a model age that may be as much as 4,200 Myr (ref. 22). Eclogite xenoliths studied in these investigations do not contain diamonds, but many other Roberts Victor eclogites are diamondiferous. Ancient, alluvial diamonds of unknown paragenesis and primary source occur in the 2,500-Myr-old Witwatersrand conglomerates in the central part of the Kaapvaal craton[23]. High $^3He/^4He$ values found in some South African diamonds of unknown specific source suggest diamond crystallization in the early Archaean[24]. A model argon age of 3,100 Myr has been obtained for a single diamond from Arkansas[25], but similar measurements have not yet been performed on South African diamonds.

Crystallization temperatures estimated for diamonds from seven Kaapvaal kimberlites show the large range of 900–1,400 °C (Fig. 2). There is a difference in the estimated temperatures for diamonds with eclogitic and peridotitic inclusions; temperatures for the eclogitic suite are confined to the range 1,100–1,400 °C, whereas the peridotitic suite has the full range 900–1,400 °C, but with a concentration in the range 900–1,100 °C. Geographical differences, however, appear in these data. Most of the inclusion sets with crystallization temperatures <1,100 °C are from the Finsch pipe (Fig. 2). Other suites of diamonds with inclusions of both peridotitic and eclogitic parageneses (in separate diamonds) from the Premier and Roberts Victor kimberlites have higher crystallization temperatures, predominantly >1,200 °C (refs 26, 27). Differences in mean carbon isotope composition between diamonds from the Finsch and Premier kimberlites have also been noted[28].

The beginning of melting for peridotite (or kimberlite) in the presence of H_2O and CO_2 at 50 kbar is ~1,150 °C (ref. 29). This fact led Boyd and Finnerty[19] to suggest that peridotitic diamonds with crystallization temperatures below 1,150 °C might be of sub-solidus origin. An obvious corollary to this suggestion is evident from the data in Fig. 2; that is, eclogitic diamonds and perhaps some peridotitic diamonds with crystallization temperatures >1,150 °C might be igneous. Diamonds with crystallization temperatures in the lower part of the range shown in Fig. 2 are believed to approach ambient conditions most nearly, regardless of the nature of the fluid from which they were precipitated.

Evidence from many xenolith suites supports the concept of a peridotite-rich, cratonic lithosphere with a thickness of 150–200 km. Recent seismic studies have provided data that are concordant with this model[30], and evidence for seismic velocity drops in the depth range 150–200 km (ref. 31) may correlate with geotherm inflections. Jordan[32] has suggested that thick continental tectospheres developed as early as 2,000–2,800 Myr.

Burke and Kidd[33] have argued that the rarity of minimum-melting granites in the Superior Province is evidence that Archaean gradients beneath shields were not much steeper than are those of the present time. Analogous evidence led Davies[34] to propose that Archaean cratons were underlain by relatively cool 'root zones' or lithosphere that extended to a depth of 200 km where the palaeotemperature was near 1,500 °C.

The results obtained from the chemical and isotopic studies of diamond inclusions are evidence that the Kaapvaal craton, and perhaps other cratons, were stabilized earlier (3,300 Myr) than hitherto believed. Moreover, these data appear most concordant with thermal models for the Earth during the Archaean in which increased heat generation from radioactive sources was lost primarily through the ocean basins (see ref. 34).

Geochemistry of Holocene volcanic rocks associated with ridge subduction in Baja California, Mexico

G. Rogers*, A. D. Saunders*, D. J. Terrell†, S. P. Verma‡ & G. F. Marriner§

* Department of Geology, University of Leicester, Leicester LE1 7RH, UK

Although the geochemistry of magmatism associated with the subduction of oceanic lithosphere is well understood[1–6], the geochemical signature of lavas produced shortly after subduction of an oceanic spreading centre has not been characterized. The Baja California peninsula in Mexico provides an ideal scenario to study the latter process. Geophysical models indicate that, in response to oblique collision of the ancestral East Pacific Rise (EPR) with the western seaboard of North America at ~29 Myr, subduction of the Farallon plate was succeeded by the progressive southwards development of a transform fault system[7–9]. At 12.5 Myr a considerable length of the EPR was simultaneously subducted beneath Baja, thus terminating subduction processes along this segment[10]. By 3.5 Myr the locus of transcurrent faulting had switched from the west of Baja to within the developing Gulf of California, coupling Baja to the Pacific plate[11–13]. We present here data for Holocene volcanic rocks from Baja California Norte which show that post-ridge subduction volcanism has a distinctive geochemistry. These results have important consequences for the interpretation of ancient orogenic belts.

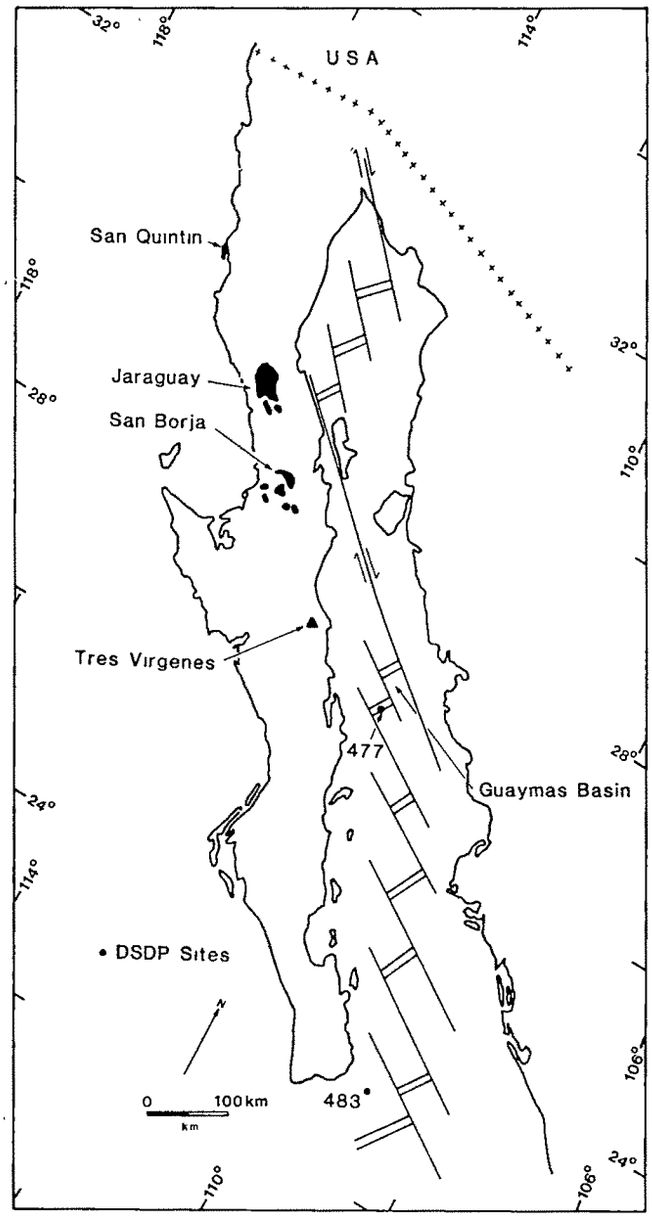

Fig. 1 Map depicting areas of Upper Cenozoic-Holocene volcanism in Baja California showing the three volcanic fields of Baja California Norte, and the Tres Virgenes volcano of Baja California Sur.

In sympathy with the changing tectonic regimes, there are variations in the geochemistry of associated volcanism. Calc-alkaline lavas related to subduction were widespread until ~15 Myr (refs 11, 16, 17) since when there has been an increase in tholeiitic and alkaline products[11,14–18], although the currently active Tres Virgenes stratovolcano[19] is also calc-alkaline[20]. As shown in Fig. 1, Holocene volcanism in northern Baja California is confined to three main areas, namely around San Quintin, Jaraguay and San Borja, although there are isolated flows elsewhere in the region[16,17,21,22]. Additionally, the lavas at San Quintin contain the only known occurrences on the peninsula of lherzolite nodules[23].

All the rocks studied form blocky flows erupted from small cones, and are fresh and sparsely porphyritic (<5%). They are morphologically very young: flows at San Quintin which overlie

midden deposits dated at 5,000–6,000 yr BP (ref. 16) have a much greater vegetation cover than either the Jaraguay or San Borja lavas, suggesting an even younger age for the latter. Moreover, a lava underlying the Jaraguay flows discussed here has yielded a whole rock K–Ar age of 2.69 Myr (unpublished data). Petrographically, the lavas from San Quintin are distinct in having olivine as the dominant phenocryst phase with subordinate labradorite and rare clinopyroxene. Groundmasses contain olivine, magnetite, plagioclase microlites and augite. In contrast, most of the lavas from San Borja contain only sparse olivine crystals, and clinopyroxene is the major, and often only, phenocryst phase. Pilotaxitic groundmasses comprise plagioclase microlites, magnetite, clinopyroxene and an iron-rich mesostasis. The Jaraguay and a few San Borja flows are intermediate between the two in having dominant phenocrystal olivine, subordinate clinopyroxene and trace plagioclase. Plagioclase microlites, clinopyroxene and an iron-rich mesostasis form the groundmass.

Representative analyses of the lavas from the three volcanic fields are presented in Table 1, together with samples drilled from the Guaymas Basin in the central part of the gulf of California[14], and from the mouth of the gulf[24]. The lavas from San Quintin are distinct from those of Jaraguay and San Borja, being nepheline-normative alkali basalts whose elemental variations reflect fractional crystallization of olivine + Cr spinel[22]. Zr/Nb (4.5–5.4), K/Rb (410–482) and La/Nb (0.66–0.75) ratios are lower than N-type mid-ocean ridge basalts (MORB) but comparable to other suites of alkali basalts[25]. Chondrite-normalized La/Y ratios ($(La/Y)_N$) of 6.8–7.8 indicate slight light rare-earth elements (LREE) enrichment, but there is no marked depletion of the heavy rare-earth elements (HREE). In contrast, rocks from Jaraguay are olivine or quartz normative basaltic andesites. The most striking geochemical feature is their high Sr contents (2,068–2,152 p.p.m.) which results in low Rb/Sr (0.0031–0.0043) and high Sr/Zr (12.5–13.5) ratios. Rb is also depleted with respect to K_2O, the K/Rb ratios varying from 1,716 to 2,314 (Fig. 2). Furthermore, all the large-ion lithophile elements (LILE) are enriched relative to the high field strength elements (HFSE) (for example, La/Nb = 5.2–6.7). Inter-HFSE ratios, however, have MORB-like affinities (for example, Zr/Nb = 29.3–37.0; Hf/Ta = 13.8–15.1). The lavas are strongly LREE enriched (Fig. 3) with $(La/Yb)_N = 45.7–47.9$ and $(La/Y)_N = 17.5–22.8$; moreover, Yb and Y show pronounced depletion with $Yb_N = 3.5–3.6$ and $Y_N = 3.95–4.75$. The high MgO contents of 6.2% at 55% SiO_2 classify the rocks as magnesian basaltic andesites; high Ni (150–157 p.p.m.) and Cr (199–221 p.p.m.) concentrations preclude much low-pressure fractionation.

The Holocene lavas from the San Borja volcanic field are also magnesian basaltic andesites with MgO ~5.0% at 55% SiO_2; these rocks, however, have undergone low-pressure fractionation of olivine + clinopyroxene + Cr spinel as indicated by their generally lower Ni and Cr contents (68–140 p.p.m. and 144–242 p.p.m. respectively). They show features of the Jaraguay lavas; high Sr (2,163–2,609 p.p.m.) and Ba (946–1161 p.p.m.) concentrations, high Sr/Zr (9.5–10.7), K/Rb (1,484–2,177) and La/Nb (4.2–5.9), and low Rb/Sr (0.0035–0.0046) ratios. $(La/Y)_N$ ratios (18.4–23.9) are very fractionated, with $Y_N = 4.3–6.7$. Zr/Nb ratios (23.3–39.5) overlap those of Jaraguay but are often a little more enriched (Fig. 2).

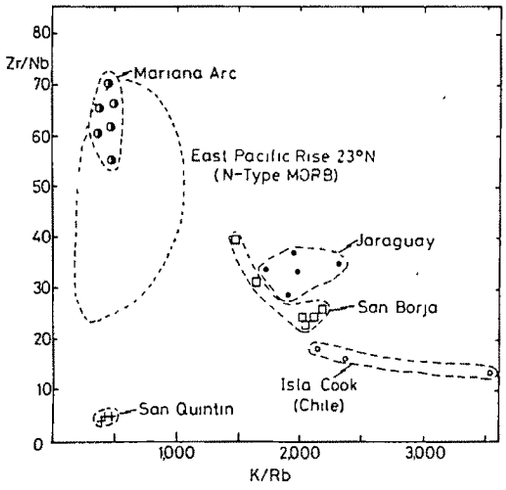

Fig. 2 Zr/Nb versus K/Rb for Holocene lavas from San Quintin, Jaraguay and San Borja volcanic fields of Baja California Norte and Isla Cook, southern Chile. MORB from EPR 23° N (ref. 24) and arc lavas from the Marianas[4] are shown for comparison.

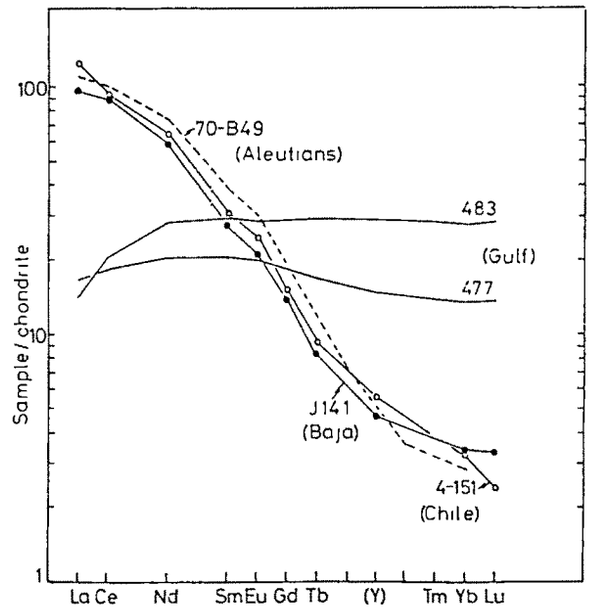

Fig. 3 Chondrite-normalized REE plot for the lavas from Jaraguay (J14.1) (unpublished data); the Gulf of California (Site 483: Gulf Mouth[24], Site 477; Guaymas Basin[14]; seeTable 1); Isla Cook, Chile (4–151)[32], and western Aleutian Ridge (70–3 49)[31]. All analyses by instrumental neutron activation analysis

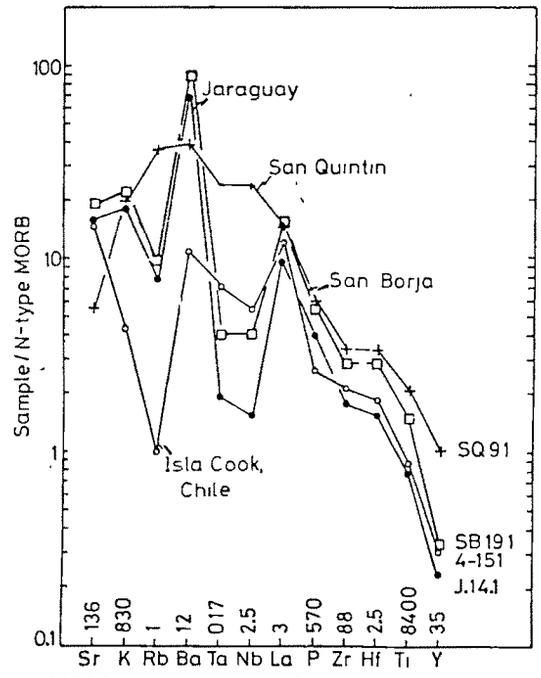

Fig. 4 MORB-normalized trace element plot for the Holocene lavas of Baja California Norte and Isla Cook, Chile[32] (Table 1). MORB-normalizing values from ref. 43.

The depletion of Y and HREE in the San Borja and Jaraguay lavas attests to the importance of garnet as a residual phase during melting, assuming that the source was not already HREE depleted. MORB-normalized plots for the three lava types (Fig. 4) reveal that whereas San Quintin is similar to other within-plate alkali basalts[5,25], Jaraguay and San Borja have pronounced Nb depletions relative to LILE, a characteristic of subduction-related magmatism[4–6]. Interestingly, recent basalts recovered from the Guaymas Basin[14] and from Isla Tortuga[18] (a tholeiitic seamount), both in the central part of the Gulf of California, also portray enrichments of LILE compared with those from the gulf mouth where there is active spreading[20]. It thus appears that this enrichment in alkalis and LREE is inherited from the subduction regime which was operative beneath north-west Mexico 12.5 Myr ago, and is superimposed on a MORB-type mantle.

High-magnesian andesites have been reported from other localities[26–37]. Those from the Bonin Islands, Mariana Forearc and Trench and Cape Vogel[26–30] have been ascribed to the boninite series. They differ from the Jaraguay and San Borja lavas in having much higher MgO (>9% at 55% SiO_2) and much lower TiO_2 and Zr contents, higher K/Rb and lower Rb/Sr ratios and very depleted REE concentrations (<20 times chondrite and usually <10). Petrographically boninites are also distinct in having phenocrysts of orthopyroxene or clinoenstatite, while lacking olivine. The magnesian andesites from Baja California are thus not members of the boninite series. However, magnesian andesites similar to Jaraguay and San Borja have been described from several volcanic arcs[31–35]. Those from the Setouchi volcanic belt in Japan are considered to be primary melts from hydrous mantle[34–37]. In the Aleutians, Kay concluded that the highly fractionated REE profiles (and, incidentally, the high Sr contents) of magnesian andesites (Fig. 3) were produced by eclogite melting. However, this cannot be the case in Baja as the enrichment of Sr and the depletion of Rb are too extreme. Magnesian andesites recently reported from Isla Cook in southernmost Chile[32,33] bear a close resemblance to the Jaraguay and San Borja samples, particularly in their high Sr and very low Rb contents (Table 1, Fig. 3). They have depleted Sr and Nd isotope systematics ($^{87}Sr/^{86}Sr = 0.70268–0.70280$; $^{143}Nd/^{144}Nd = 0.513136$), 'mantle' $\delta^{18}O$ (5.1–5.7) and Pb isotopes similar to other volcanic centres in the southern Andes[33,38]; they are thought to have risen through the crust with little interaction. It is not possible, with the available data, to preclude crustal contamination during the formation of the Jaraguay and San Borja lavas. It is, however, unlikely. First, the low Rb content and concomitant very low Rb/Sr, Rb/Ba and Rb/La ratios imply that assimilation of sialic upper crust has been minimal. Second, the low $^{87}Sr/^{86}Sr$ ratio (0.7037) reported for the Jaraguay lavas[9] precludes significant contamination either of the source by subducted sediment, or of the ascending magma. The isotope data for Jaraguay, Aleutians and southern Chile also rule out incorporation of pelagic, calcareous sediments in the magma sources to explain the very high Sr contents of these lavas.

Most interesting, however, is the apparent tectonic association of these magnesian andesites with the subduction of an actively spreading oceanic ridge. Isla Cook, for example, is sited on a transcurrent fault zone at the junction of the South American, Antarctic and Scotia plates where subduction has virtually ceased following the northward migration of the Chile Rise–Peru–Chile Trench triple junction in response to the oblique subduction of the Chile Rise. The magnesian andesites from the

Aleutians have an estimated middle Miocene age[31], which overlaps the final stages of the effects of subduction of the Kula Ridge[39]. The Setouchi high-magnesian andesites were erupted 12–14 Myr ago[37], a date which succeeds cessation of subduction of the Shikoku Basin crust at the Nankai Trough, during which process there was consumption of part of the marginal basin spreading centre[40]. Finally, the Baja Holocene lavas were erupted 12.5 Myr after subduction of the EPR. Although Moore[41] considers that the Baja California peninsula has moved northwest by ~240 km during the past 4 Myr, this movement has been along the Pacific margin and thus over regions of the mantle into which the ancestral EPR had already been subducted.

The association of these magnesian andesites (here termed Bajaite series rocks) with ridge subduction may result from increased thermal input into the mantle beneath the arc[42] and/or from modification of the chemical input from the subducting slab compared with periods of 'normal' subduction of oceanic lithosphere. It is evident that volcanism associated with ridge subduction has a distinctive geochemistry, namely the generation of magnesian andesites with fractionated REE profiles, low Rb/Sr and high K/Rb, Sr/Zr, La/Rb and La/Nb ratios superimposed on a MORB-type HFSE signature. The mechanism for producing such compositions is unclear, but probably involves garnet as a residual phase during melting of a source variably enriched in Sr, and depleted in Rb, relative to most island arc magma sources. The transcurrent fault-related setting of Baja California and Isla Cook may allow magmas to rise rapidly through the crust with insignificant contamination and only minor fractionation.

We thank J. Tarney, N. J. Norry and I. W. Luff for constructive criticism. Samples from Isla Cook were provided by M. Suarez. The study is supported financially by NERC grant GR3/4957.

Cenozoic weathering covers in Buchan, Scotland and their significance

A. M. Hall

Fettes College, Carrington Road, Edinburgh EH4 1QX, UK

Isolated occurrences of chemically weathered rock or saprolite are common in many formerly glaciated areas around the North Atlantic[1–6]. These pockets of saprolite are widely regarded as remnants of Cenozoic deep-weathering covers which existed before the first extensive Northern Hemisphere glaciations at ~2.4 Myr (ref. 7) and their apparent survival has long been used as evidence for the local ineffectiveness of glacial erosion[2,4,8,9]. However, the scarcity of correlative deposits means that the age and significance of these fragmented saprolites are uncertain. I report here the results of a detailed survey which shows that in Buchan, Scotland, a combination of Cenozoic tectonic stability and extremely limited Pleistocene glacial erosion has allowed the preservation of deep-weathering covers of probable Miocene to early Pleistocene age on a scale not previously reported from any other formerly glaciated area.

Buchan is an area of subdued relief lying at the angle of north-east Scotland (Fig. 1). The geology consists largely of Precambrian to Dalradian metamorphic rocks intruded by Caledonian acid and basic igneous masses[10]. The only sedimentary rocks onshore are Devonian Old Red Sandstones but thick accumulations of Mesozoic and Palaeogene sediments lie offshore.

In Buchan, saprolites are continuous over wide areas[11] and maximum depths exceed 60 m in boreholes[12,13] (Fig. 2). All major rock types are affected and alteration decreases with depth, indicating that weathering is a product of subaerial rather than hydrothermal alteration.

Within major lithologies, saprolite characteristics vary widely and reflect important differences in the degree of chemical alteration. Data on granulometry and clay mineralogy, backed by geochemistry, indicate that two main weathering types exist. Most widespread is the gruss weathering type in which a relatively low degree of alteration has caused disintegration into a granular sand. Gruss is characterized by an abundance of little-altered primary minerals, low fines contents, low soluble base losses and heterogeneous and immature clay mineral assemblages (Table 1). The second weathering type, clayey gruss, is virtually confined to central Buchan. Here advanced alteration has reduced parent rocks to a sticky, clayey silty sand. Detrital primary mineralogy is dominated by quartz, fines contents are relatively high, and clay mineral assemblages consist of mature kaolinite–illite suites. At several sites, clayey grusses are rubefied due to the presence of haematite and goethite. This distinction between grusses and clayey grusses is comparable with others made for granite weathering covers in Europe south of the limits of Pleistocene glaciation[5,14,15].

The relative ages of the two weathering types can be established using evidence from correlative deposits, saprolite mineralogy and geomorphology. All deep weathering in north-east Scotland must predate the last glaciation as materials reworked from subjacent and adjacent saprolites form a major component of Devensian tills and congeliturbates[11,16,17]. Evidence that many gruss weathering profiles are of middle Pleistocene age or older is provided by: (1) the presence of weathered biotite and feldspar and inherited clays throughout the middle to late Pleistocene sequence of glacial, glacifluvial and periglacial deposits at Kirkhill[18,19]; and (2) the presence of hydromorphic iron and manganese minerals in weathering profiles now occupying free-draining sites[20]. These minerals indicate that weathering had already extended close to and probably below the water table before a major change in groundwater drainage status during the Pleistocene in response to regional drainage incision.

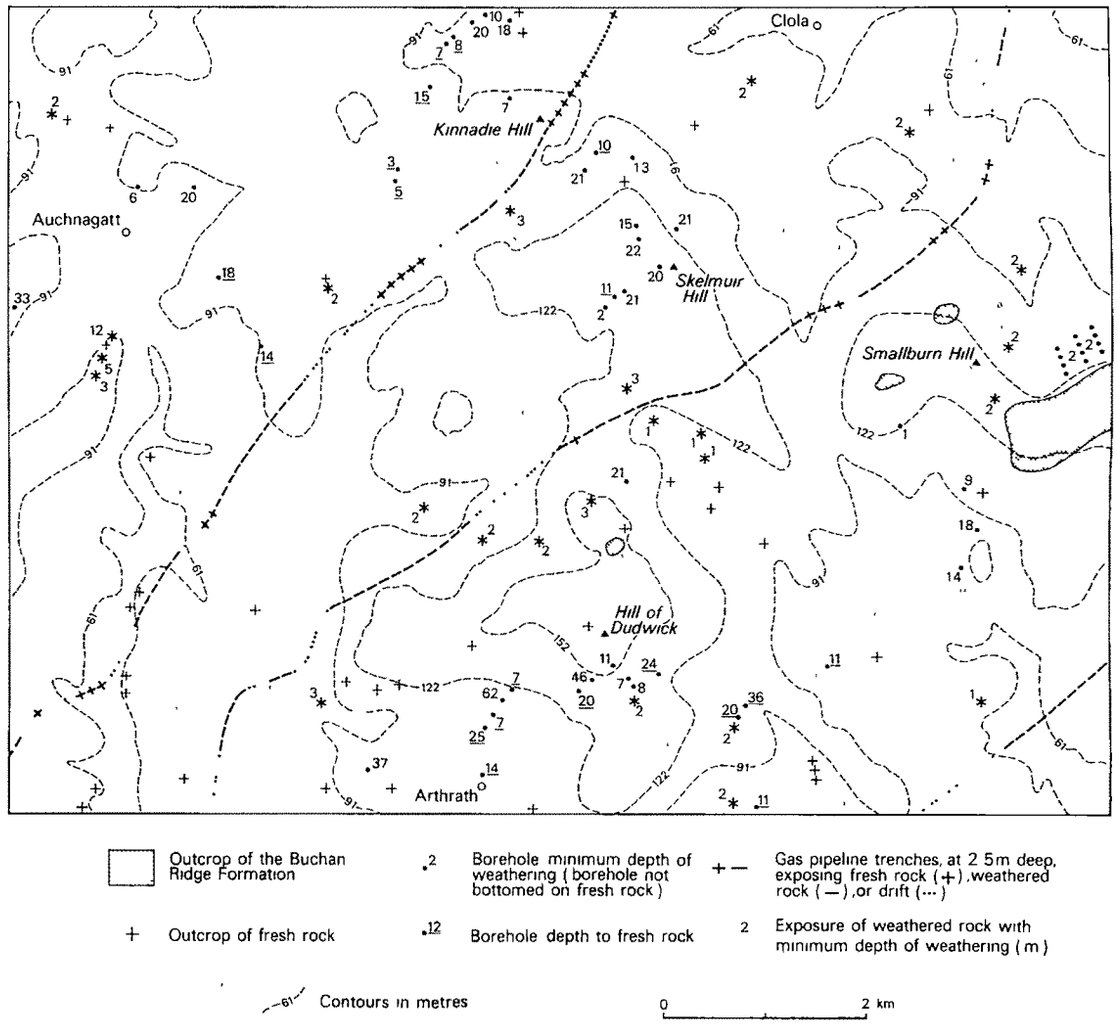

Fig. 2 Deep weathering patterns in central Buchan.

Suggestions that deep weathering is wholly of interglacial age[21] may also be rejected in view of the disparity between rates of rock alteration during the present interglacial[2], the relatively short durations (~10–30 kyr) of previous interglacials[22] and observed depths of weathering. Formation before the glacial Pleistocene is indicated.

The dominance of kandite and illite clay mineral assemblages in acid igneous and metamorphic grusses[20] and hydrous mica-amorphous iron oxide assemblages in basic igneous grusses[16] indicates weathering under humid temperate environments. However, the intensity of alteration shown by the clayey grusses requires warmer, probably subtropical climates[14,15]. Marine palaeotemperatures[23] and terrestrial palynology[24] indicate that subtropical climates last prevailed in the Scottish area during the middle Miocene (10 Myr). Major climatic cooling after this time[23,24] is reflected in the mineralogy of North Sea well samples, with appearance of chlorite and amphibole and increases in illite and feldspar contents[25,26], and in a transformation in styles of rock weathering throughout western Europe with the first development in the Tertiary of sandy saprolites retaining significant amounts of detrital feldspar and biotite[5,14]. I conclude that the clayey gruss weathering type predates the late Miocene and that the gruss weathering type developed continuously throughout the Pliocene and early Pleistocene.

The clayey grusses are virtually confined to a north–south belt of high ground in central Buchan (Fig. 1) which represents the remnants of a Miocene or older landsurface. Around Hill of Dudwick, the clayey grusses are juxtaposed with and underlie outcrops of the Buchan Ridge Formation. These intensely-weathered gravel deposits comprise clasts of rolled Cretaceous flint and Dalradian quartzite with a matrix of quartz sand and kaolinitic fines[27], and are widely regarded as Tertiary in age[28–30]. At Moss of Cruden, the gravels are >25 m thick and include clasts of little-travelled nodular flint. The preservation of such large volumes of flint suggests that Buchan has remained close to base-level since marine transgression in the late Cretaceous. This reflects the position of Buchan at the stable eastern extremity of the Scottish Highlands, an area repeatedly tilted westwards towards the rapidly subsiding North Sea basin in the Tertiary[31].

Tectonic stability has been a major factor in the extraordinary development and state of presevation of Cenozoic weathering covers. However, the survival of friable saprolites also demonstrates the singular ineffectiveness of Pleistocene glacial erosion in Buchan, where a succession of cold-based ice sheets have done little to modify Neogene landsurfaces[19].

Pockets of gruss-type saprolites occur widely in other glaciated areas bordering the North Atlantic[1–6]. Analogies with Buchan suggest that during the Neogene, lowland crystalline terrains were extensively weathered under temperate environments, with depths of weathering exceeding 30 m on interfluves. Where saprolites have survived glaciation and can be shown not to be the products of hypogene alteration[32] or exceptionally deep alteration down fault zones[12,20], it can be proposed that local Pleistocene glacial erosion has amounted to at most the removal of a few tens of metres of regolith and exposure of the basal surface of weathering. Such estimates can be reconciled with regional evidence of deep Pleistocene erosion deduced from the

volumes of offshore sediments[33,34] by recognizing the selectivity of glacial erosion. Enclaves of little-modified Neogene relief have survived in parts of eastern Canada[4,35], eastern Greenland[36], Fennoscandia[5,37–39] and the British Isles[2,9,40] where local factors, including remoteness from ice accumulation centres, low gradients and diffluent flow patterns, have combined to maintain basal ice below its pressure melting point and so prevent significant glacial erosion[36]. Finally, the thicknesses of saprolite reported here would suggest that material reworked from preglacial Cenozoic weathering profiles forms a major, but largely overlooked component of glacial tills[37,41].

This work was carried out during tenure of a Research Scholarship from the University of St Andrews. A grant towards the cost of illustrations was provided by the Carnegie Trust for the Universities of Scotland. Borehole information was provided by the Department of Geology, University of Aberdeen, RioFinEx Ltd and the British Geological Survey, Edinburgh.

Isotope composition of sulphates generated by bacterial and abiological oxidation

Robert O. van Everdingen

National Hydrology Research Institute, 4616 Valiant Drive, Calgary, Alberta, Canada T3A 0X9

H. Roy Krouse

Physics Department, The University of Calgary, Calgary, Alberta, Canada T2N 1N4

Oxygen isotope compositions of secondary sulphates provide a potentially powerful tool for elucidating mechanisms of sulphur oxidation. Such studies should reveal the consequences of various anthropogenic sulphur contributions to the environment, including gaseous emissions, aqueous solutions and elemental sulphur dust. At mining sites, metal sulphides may be oxidized *in situ*, giving rise to acid mine waters. The environment can receive these compounds from natural sources also, for example volcanoes, sulphurous springs and sour-gas seeps. There are many fundamental questions concerning the specific oxidation reactions and associated kinetics. In principle, isotope data from appropriate experiments can be used to address such questions. In the case of acid mine drainage, the approach of Taylor *et al.*[1] is noteworthy. Here we present a critical examination of their results and suggest a novel method of determining the kinetic isotope effects identified with the incorporation of O_2 and H_2O-oxygen by SO_4^{2-}.

Oxygen isotope data may provide information about redox reactions in the sulphur cycle when sulphur isotope data fail to do so. For example, SO_4^{2-} in subsurface water may be partially reduced to HS^- in deeper anaerobic enviroments, and the reduced product may be subsequently re-oxidized near the surface. The sulphur isotope composition may be conserved if processes such as metallic sulphide deposition or H_2S escape are absent; in this case there would be no sulphur-isotope evidence of the reduction–re-oxidation sequence. However, during re-oxidation, oxygen incorporated in the product SO_4^{2-} can be derived from both O_2 and H_2O molecules; this generally produces $\delta^{18}O$ values different from those of the original SO_4^{2-}. The above scenario has been documented for sulphates in several springs in western Canada[2–4].

Taylor *et al.*[1] presented a scheme whereby a plot (their Fig. 2) of $\delta^{18}O$ values of SO_4^{2-} versus those of associated H_2O can be used to evaluate the relative participation of two specific oxidation reactions. In our laboratory, $^{18}O/^{16}O$ analyses have been done on sulphate produced by oxidation of biogenic H_2S (near sulphurous springs)[2,3] and of metal sulphides (in acidic springs)[3]. It would seem that the approach of Taylor *et al.*[1] could be applied to these data. However, when this approach was attempted, it became apparent that their Fig. 2 required refinement.

Taylor *et al.*[1] cited three reactions identified with the oxidation of FeS_2:

$$FeS_2 + 14Fe^{3+} + 8H_2O \rightarrow 15Fe^{2+} + 2SO_4^{2-} + 16H^+ \quad (1)$$

$$Fe^{2+} + \tfrac{1}{4}O_2 + H^+ \rightarrow Fe^{3+} + \tfrac{1}{2}H_2O \quad (2)$$

$$FeS_2 + \tfrac{7}{2}O_2 + H_2O \rightarrow Fe^{2+} + 2SO_4^{2-} + 2H^+ \quad (3)$$

In reaction (1) all sulphate oxygen (O_s) is derived from water molecules, whereas in reaction (3) 87.5% of the sulphate oxygen is derived from molecular oxygen and 12.5% from water molecules. Sulphates produced by the two reactions have different $\delta^{18}O_s$ values because of the generally large difference between the $\delta^{18}O$ values of O_2 and H_2O ($\delta^{18}O_a$ and $\delta^{18}O_w$, respectively).

Even if reactions (1) and (3) apply, there are two reasons why the isotope composition of oxygen in the sulphate does not necessarily reflect the stoichiometric proportions. First, a reactant atom need not end up in the product; it may instead enter a solvent molecule or another ion, depending on the reaction mechanisms and isotope exchange reactions. Second, reaction (2), the rate-limiting step for reaction (1), generates H_2O with a $\delta^{18}O$ value similar to that of O_2, which may affect the isotope balance of reaction (1). In the absence of data bearing on these possibilities, the stoichiometry of reactions (1) and (3) will be assumed to apply to the isotope composition, as done by Taylor *et al.*[1].

In their Fig. 2, Taylor *et al.*[1] plotted $\delta^{18}O$ values for SO_4^{2-} in acid mine waters ($\delta^{18}O_s$) against those for associated H_2O

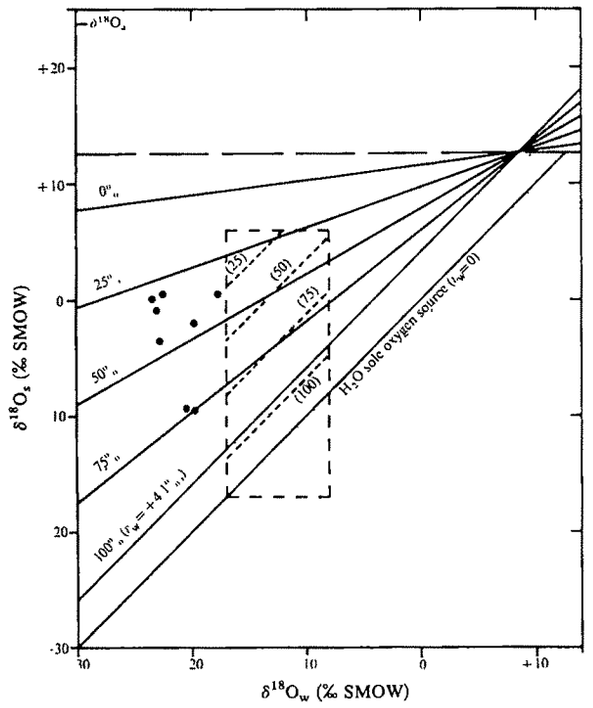

Fig. 1 Expected $\delta^{18}O_s$ values for secondary sulphates produced by oxidation of pyrite plotted against the $\delta^{18}O_w$ value of associated water, for relative contributions by reaction (1) ranging from 0 to 100%. Broken lines are from Taylor *et al.*[1]. Points represent data for acidic springs in western Canada.

($\delta^{18}O_w$). They drew a line representing zero difference between $\delta^{18}O_s$ and $\delta^{18}O_w$, labelled 'H_2O sole O_2 source', and a parallel line, offset by about +3.5‰ and labelled 100%, representing sulphates produced exclusively by reaction (1). The offset reflects the estimated kinetic isotope effect for the reaction. Three further lines, corresponding to 75, 50 and 25% contribution by reaction (1) were drawn parallel to the first two lines.

When we plotted $\delta^{18}O_s$ values for dissolved sulphates from acidic spring waters in western Canada, associated with lower $\delta^{18}O_w$ values (−23‰ standard mean ocean water, SMOW) than the data of Taylor *et al.*[1], an unrealistic contribution from reaction (3) was indicated. On further reflection, it was realized that the lines labelled 75, 50 and 25% should not be parallel. This can be readily appreciated by assuming a hypothetical reaction whereby all oxygen in the product sulphate is derived from O_2. In that case, the plot would be a horizontal line, as $\delta^{18}O_s$ would be independent of $\delta^{18}O_w$. Whereas the line for 100% contribution of sulphate oxygen by reaction (1) should be parallel to the line for 'H_2O sole oxygen source' and have a slope of unity (Fig. 1), decreasing contributions by reaction (1) would produce lines with progressively decreasing slopes.

The above considerations are incorporated in the isotope balance equation

$$\delta^{18}O_s = Y(\delta^{18}O_w + \varepsilon_w) + (1-Y)\,[0.875\,(\delta^{18}O_a + \varepsilon_a) + 0.125(\delta^{18}O_w + \varepsilon_w)] \quad (4)$$

in which Y is the fraction of SO_4^{2-} produced by reaction (1); ε_w and ε_a represent shifts in $\delta^{18}O_w$ and $\delta^{18}O_a$ values due to kinetic isotope effects during incorporation of O_w and O_a into sulphate. Using $\varepsilon_w = +4.1$‰ (ref. 1), $\varepsilon_a = -11.2$‰ (ref. 1) and $\delta^{18}O_a = +23.8$‰ (ref. 5), equation (4) can be rewritten as

$$\delta^{18}O_s = \delta^{18}O_w(0.875\,Y + 0.125) + (11.5375 - 7.4375\,Y) \quad (5)$$

Lines for 75, 50, 25 and 0% contribution by reaction (1), calculated using equation (5), are plotted in Fig. 1; they converge and intersect at the point where $\delta^{18}O_s = +12.6$‰ and $\delta^{18}O_w = +8.5$‰. This convergence means that at low latititudes, where $\delta^{18}O_w$ values are closer to SMOW, it is more difficult to differentiate contributions from individual reactions than at higher latitudes, where $\delta^{18}O_w$ values may be lower than −30‰.

The 75, 50 and 25% lines from Fig. 2 of Taylor *et al.*[1] have been added to our Fig. 1, together with $\delta^{18}O$ data from acidic springs in western Canada. It is readily seen that extrapolation of the parallel lines of Taylor *et al.*[1] would indicate very different proportions for the relative contributions by reactions (1) and (3) to these sulphates.

Figure 1 also suggests that oxidation of FeS_2 in contact with water having a $\delta^{18}O_w$ value of +8.5‰ should produce sulphate having a $\delta^{18}O_s$ value equal to +12.6‰, independent of the relative contributions by reactions (1) and (3). It should be possible to verify this point experimentally; this in turn would provide a check on the values for ε_a and ε_w, as well as on the validity of the assumption that the stoichiometry of reaction (3) applies, or whether the overall approach is too simplified.

Fluorescent bands in massive corals result from terrestrial fulvic acid inputs to nearshore zone

Kevin Boto & Peter Isdale

Australian Institute of Marine Science, PMB No. 3, Townsville M.C., Queensland 4810, Australia

The discovery of yellow-green fluorescent bands in the skeletons of massive corals from inshore waters of the Great Barrier Reef, and the temporal and spatial correlations of these bands with adjacent river flow[1], prompted an investigation into the substances responsible for the phenomenon. We have determined that all regions of the coral skeleton contain fulvic acids[2,3] which impart a blue background fluorescence. The yellow-green fluorescent bands found only in inshore coral appear to result from enhanced concentrations of low-relative molecular mass (<10,000) fulvic acids from adjacent river input. These compounds are ubiquitous, and the yellow-green banding phenomenon can be expected to occur in massive corals located near to significant river systems. In the widely distributed genus *Porites*[4], the great age of the largest colonies[1] means that extremely long, highly resolvable records of coastal runoff exist throughout tropical nearshore seas.

Fluorescence spectra of coral core sections were obtained using a modified version of the apparatus described previously[1]. The new version employed a 150-W mercury arc excitation beam, passed through a precision 360-nm bandpass filter and chopped at 285 Hz. A quartz optical fibre focused this beam into a 3-mm spot on the coral surface. Another optical fibre passed the fluorescence emitted from the coral surface into the monochromator and detector system of a Varian AA6 atomic absorption spectrophotometer. This instrument was tuned to the chopper frequency to eliminate interference from ambient light.

The fluorescence spectra for the banded and background regions of the coral (Fig. 1) are very broad, with maxima at 440–460 nm. These are indicative of humic and fulvic acids, mixtures of complex polyphenolic compounds with a wide range of relative molecular mass ($M_r < 5\times10^2$–5×10^4). Fulvic acids are generally in the lower M_r range ($<5\times10^2$–3×10^4) and are defined as the fraction of the humic material soluble at *p*H 1 (ref. 2). The ubiquitous blue fluorescence found in marine and terrestrial waters[5] is thought to result from the presence of these

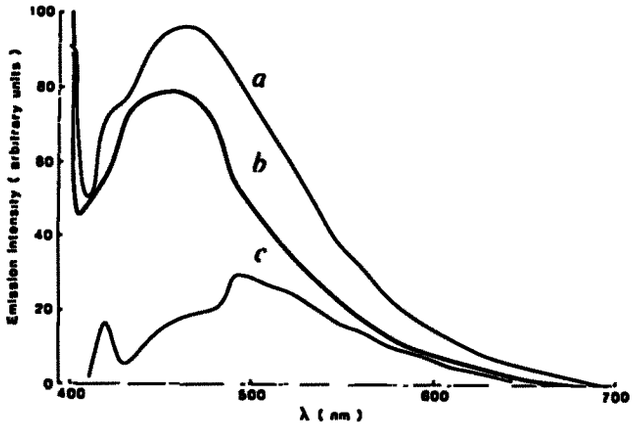

Fig. 1 Emission spectra of the, *a*, 'yellow-green band'; and *b*, background regions of an inshore *Porites* spp coral skeleton. The 'yellow-green band' corresponds to the large January 1974 flow recorded in the nearby Burdekin River[1]. *c*, Direct subtraction of *b* from *a*

humic compounds. In particular, the high fluorescence efficiency and refractory nature of terrestrial humics has enabled their use as conservative tracers of fluvial input to coastal waters[3,6]. The molecular structures and the nature of the fluorescing chromophore(s) of these compounds are poorly understood[2,5], although their general fluorescent characteristics and strong metal-complexing nature have been well documented[7,8]

The following simple experiments were performed to test the hypothesis that the fluorescence in the inshore-growing corals was a consequence of humic inclusions in the crystal structure of the skeleton. All solutions were adjusted to *p*H 6.5 before obtaining fluorescence spectra using an Aminco-Bowman spectrofluorometer.

(1) Dissolution of coral samples in dilute HCl gave solutions which showed broad fluorescence excitation and emission spectra typical of humic compounds[5]. Excitation (light absorption) maxima occurred in the 320–340-nm region with distinct shoulders at 250–270 nm. Emission maxima occurred at 410–440 nm The greater wavelength of emission maxima for the intact corals (Fig. 1) is compatible with the greater degree of crosslinking and structural rigidity conferred on the humic molecules when contained in a solid matrix[2].

(2) Solutions of similar fluorescence characteristics to the above were obtained by hot alkaline (0.1 M NaOH) extraction of the crushed coral samples, denoting the existence in the skeleton of organic acid functional groups.

(3) Addition of excess Fe^{3+} to solutions obtained by acid dissolution or alkaline extraction of the coral shifted the emission maximum (+25 nm), with 30% reduction in intensity. These observations are consistent with the formation of a strong humic material-Fe^{3+} complex, and the quenching of fluorescence of these compounds by Fe^{3+} (ref. 3).

(4) Extracts of coral samples, acidified to *p*H 1, were passed through Amberlite XAD-2 resin which has a strong affinity for adsorption of humic compounds in the acid form[9] It was found that 90% of the fluorescent components were adsorbed onto the resin and could be eluted subsequently with NH_4OH solution *p*H 11.

(5) All of the fluorescent material in the coral was apparently soluble at *p*H 1, as evidenced by unchanged total fluorescence after 0.2-μm filtration. Following the usual definition[2] we shall refer to this material as fulvic acid

Comparison of the emission spectra (Fig. 1) for the background and 'yellow-green band' areas of the coral shows that their maximum differences occur in the 480–530-nm region. These differences, although small, combined with the human eye response around 540–560 nm, result in the yellow-green appearance of the bands and their remarkable visible contrast

Table 1 Apparent M_r distribution (% in each size class) of the dissolved organic carbon in acid extracts of the yellow-green fluorescent band and background regions of a coral skeleton[1]

Apparent M_r	Yellow-green Distribution* (%)		Yellow-green Fluorescence Ex	Em	Background Distribution* (%)		Background Fluorescence Ex	Em
<1,000	32.4	32.1	320	415	25.5	21.3	330	415
10^3–10^4	30.6	27.9	325	430	13.2	18.1	320	415
>10^4	37.0	40.0	325	415	61.3	60.6	332	420

Extract solutions were adjusted to *p*H 6.5 and passed through a 0.2 μm filter before ultrafiltration using Amincon UM-2 (M_r 1,000) and UM-10 (10,000) membranes[10] The fluorescence characteristics of the resulting fractions are expressed as Ex (wavelength of maximum excitation) and Em (wavelength of maximum emission (nm))

* Results of duplicate analyses

with the blue background fluorescence. We consider that the fulvic acid composition in the two distinct regions of the skeleton is sufficiently varied to impart these small but visually prominent differences in their emission characteristics. We investigated the M_r distribution of the compounds present in acid extracts of the two different regions of the skeleton. We employed Amincon ultrafilters with nominal M_r cutoffs of 10^3 and 10^5 daltons, using a similar procedure to that described by Cole *et al.*[10] The dissolved organic carbon (DOC) content of initial, filtrate, and concentrate solutions was determined using a Graentzel DOC analyser[11]. Table 1 shows that the yellow-green fluorescing region of the coral contained significantly greater ($P<0.05$) proportions of fulvic acids in the $<10^3$ and 10^3–10^5 daltons size classes than did the blue-fluorescing background region of the coral.

The synchrony of deposition of the yellow-green fluorescent bands with adjacent fluvial inputs, and the lack of such bands in mid- and outer-shelf corals[1] allows us to postulate that the enhanced fulvic acid levels in the yellow-green bands are of terrestrial origin. These terrestrial fulvics probably differ considerably in structure and chemical characteristics from the fulvic compounds generally present in sea water[12].

We were able to induce yellow-green fluorescence in the fast-growing branching coral *Acropora formosa* by incubating the colonies in local sea water to which fulvic acid extracted from a local alluvial soil had been added at either 10 or 15 mg l^{-1}. This demonstrated conclusively that the inclusion of these ambient compounds can impart the unusual fluorescence characteristics to coral skeletons.

The global distribution of massive species of *Porites* combined with the ubiquity of fulvic compounds and their ingress to nearshore environments via fluvial pathways, suggests that the fluorescent banding in inshore corals will be a general phenomenon. In accordance with previous arguments[1], it implies that centuries of rainfall/runoff analogues are available in corals from a global range of locations.

We thank our colleagues from the Australian Institute of Marine Science for assistance, especially D. Barnes, W. Bandaranayake, A Nott, E. Daniel and M. Rennie This is contribution no. 273 from the Australian Institute of Marine Science

Distinctive mammal-like reptile from Mexico and its bearing on the phylogeny of the Tritylodontidae

James M. Clark & James A. Hopson

Department of Anatomy, University of Chicago, 1025 East 57th St, Chicago, Illinois 60637, USA

The skull of an unusual new mammal-like reptile of the family Tritylodontidae, recently discovered in the Jurassic of northeastern Mexico, is described here as *Bocatherium mexicanum*. Tritylodontids are the last survivors of the great radiation of mammal-like reptiles that also gave rise to mammals at or near the Triassic–Jurassic boundary (~200 Myr ago). These superficially rodent-like herbivores coexisted with early carnivorous mammals for some 50 Myr before becoming extinct in the late Jurassic. Although eight genera are recognized, their interrelationships have remained unclear because it has been impossible to determine the direction of morphological change within this morphologically stereotyped group. Unusual specializations of the Mexican skull now permit character polarities within the family to be determined and a cladogram to be constructed. *Bocatherium* shows a close relationship to *Bienotheroides*[1] of China and *Stereognathus*[2,3] of Great Britain. It is the first mammal-like reptile and probably the oldest terrestrial vertebrate from Mexico.

Controversy remains as to the closest relatives of tritylodontids; they are either the terminal taxon of the gomphodont cynodonts, a group showing herbivorous adaptations similar to those of tritylodontids[4], or very close relatives of the earliest true mammals, with which they share many similarities[5]. The eight genera described so far are: *Tritylodon*[2] and *Tritylodontoideus*[6] from southern Africa; *Bienotherium*[7], *Lufengia*[8] and *Bienotheroides*[1] from China; *Stereognathus*[2,3] from Great Britain; *Oligokyphus* from western Europe[9] and Arizona[10]; and *Kayentatherium*[11] from Arizona. *Stereognathus* is mid-Jurassic (Bathonian)[3] and *Bienotheroides* is mid- or late Jurassic[1,12] whereas the remaining taxa are considered to be of early Jurassic age[13]. Fragmentary postcranial remains from the Los Colorados Formation of Argentina, probably late Triassic (Norian), seem to represent the oldest-known tritylodontid[14]. We have been prompted to reassess the intrafamilial relationships of tritylodontids by the discovery of a nearly complete skull with lower jaws from northeastern Mexico (collected by J.M.C. in November 1982). The specimen pertains to a new genus and species which is described below.

Division Synapsida (Theropsida)[15]

Family Tritylodontidae

Table 1 Measurements of *B. mexicanum* type (mm)

Basal skull length	51.1	
Right cheek teeth	Length	Width
M1/	4 2	5.2
M2/	4.1	5.1
M3/	4.0	5.0
M4/	4.1	5.0
M/1	5.2	3.8
M/2	5.2	3.9
M/3	5.2	4.0

Genus *Bocatherium*, gen. nov.

Diagnosis. *Bocatherium* is unique among tritylodontids in having a large boss on the lateral surface of the dentary anterior to the masseteric fossa. It differs from other tritylodontids with the exception of *Bienotheroides* and *Stereognathus* in that: (1) its maxilla is reduced to a simple, nearly cylindrical bone lacking a medially directed horizontal lamina contributing to the secondary palate, a dorsally directed facial process in contact with the nasal, and a laterally directed lamina underlying the jugal on the anterior root of the zygomatic arch; (2) its upper postcanine teeth have only two cusps in each of three longitudinal rows (other tritylodontids have at least three cusps in the central row). *Bocatherium* is distinguished from *Bienotheroides* in having a slender, rather than extremely deep, zygomatic arch. It is distinguished from *Stereognathus* (known only from isolated teeth and a left maxilla with three teeth) in having upper postcanine teeth with an oval rather than quadrangular outline in crown view.

Bocatherium mexicanum, spec. nov.

Diagnosis. As for genus.

Type. IGM 3492, Instituto de Geologia, Universidad Nacional Autonoma de Mexico, Mexico City; a skull with lower jaws, lacking the right zygomatic arch, the roof and much of the sides of the braincase.

Horizon and locality. Approximately the middle of the 400-m-thick exposed section of the La Boca Formation in Huizachal Canyon near the towns of Huizachal, Anacahuita and La Joya, 15 km south-west of Ciudad Victoria, Tamaulipas State, Mexico. The La Boca Formation consists of terrigenous sediments which lie between Permian and late Jurassic (Oxfordian) marine sediments[16–18]. The occurrence of a tritylodontid suggests a Jurassic age for that part of the formation from which the fossil was collected. However, late Triassic plant fossils are reported from discontinuous beds assigned to the La Boca Formation at a locality 12 km to the north[16]. The conflicting ages probably indicate that the La Boca Formation contains strata of both

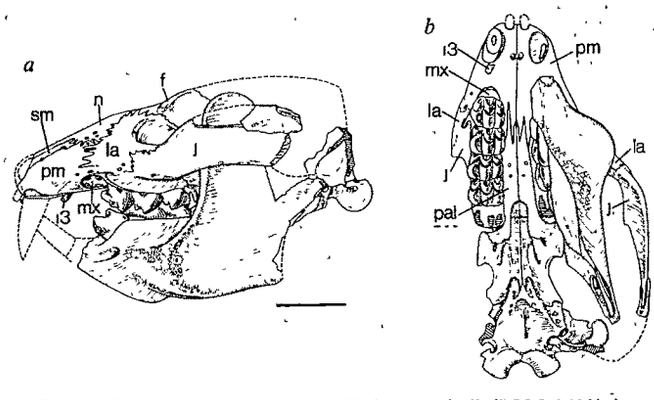

Fig. 1 *Bocatherium mexicanum.* Holotype skull (IGM 3492) in lateral (*a*) and ventral (*b*) views. Right mandible removed in *b*. Key: f, frontal; i, incisor, j, jugal; la, lachrymal; mx, maxilla; n, nasal; pal, palatine; pm, premaxilla; sm, septomaxilla. Scale bar, 1 cm.

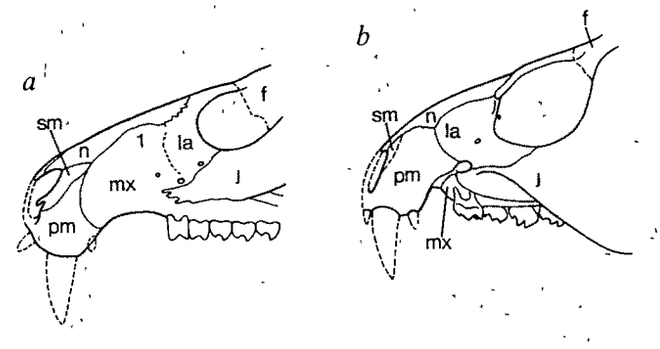

Fig. 2 Lateral views of tritylodontid facial regions representing the primitive pattern of facial bones exemplified by *Bienotherium* (*a*) and the derived pattern exemplified by *Bienotheroides*[1] (*b*). Not to scale. Key: 1, the facial process of the maxilla; other abbreviations are as in Fig. 1.

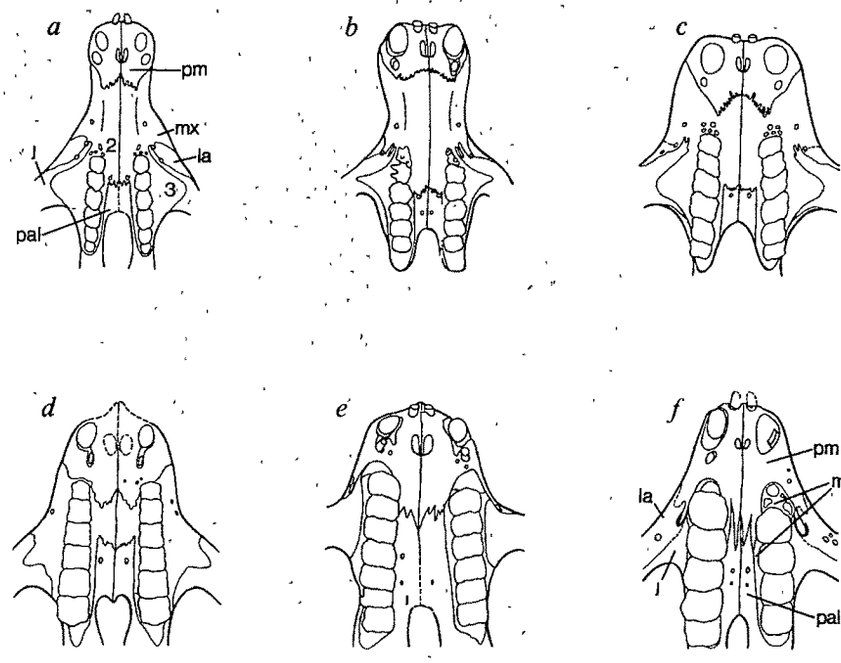

Fig. 3 Ventral views of tritylodontid skulls *a*, *Oligokyphus*[9]; *b*, *Tritylodon*; *c*, *Bienotherium*; *d*, *Kayentatherium* (H.-D. Sues, unpublished); *e*, *Bienotheroides*[1]; *f*, *Bocatherium*. Key: 2, palatine process of maxilla; 3, zygomatic process of maxilla; other abbreviations as in Fig. 1. Cusps on teeth omitted. Not to scale.

Triassic and Jurassic age, as has already been suggested by a palaeomagnetic study of rocks in this area, which identified three diachronous units within the La Boca Formation[19]. The Huizachal Canyon beds have the youngest pole position of the three, but a pole position has not been determined for rocks of the plant locality.

Bocatherium mexicanum (Fig. 1) is one of the smallest tritylodontids (Table 1), only slightly larger than *Lufengia minor*[8], but the only known skull may represent a sub-adult individual. Immaturity is suggested by the unusual depth and robustness of the dentary and by the relatively small number and large size of the cheek teeth, features characterizing juvenile but not adult *Bienotherium yunnanense* (J.A.H., unpublished). However, unlike immature individuals of other tritylodontids (see, for example, Fig. 3*d*), the teeth are of equal size rather than the posterior teeth becoming increasingly larger (Table 1). In overall morphology, *Bocatherium* resembles other tritylodontids, differing most notably in the bulbous swelling on the dentary anterior to the masseteric fossa. Basicranial and braincase structure, as preserved, are typically tritylodontid[9,20].

In the pattern of bones on the side of the face and on the palate, *Bocatherium* is strikingly different from all other tritylodontids (Figs 2*a*, 3), indeed, from all other cynodonts (cladistically including mammals), except *Bienotheroides*[1] and *Stereognathus* (J.A.H., unpublished). In these three genera, the maxilla is reduced to a nearly cylindrical element holding the roots of the teeth; thus, it lacks the usual thin laminae extending upward onto the face, medially onto the secondary palate and laterally below the jugal. *Bocatherium* and *Bienotheroides* (Figs 2*b*, 3), and by inference *Stereognathus*, show the following specialized features. The premaxilla is greatly enlarged so that it is in contact with the nasal and the anteriorly expanded lachrymal on the side of the face and the anteriorly expanded palatine on the secondary palate. The jugal is expanded anteroposteriorly on the lateral surface of the maxilla to form a long flat vertical contact. This contact facet is seen on the type specimen of *Stereognathus ooliticus*, usually described as a right maxilla[2,3] but actually a left (J.A.H., unpublished). Opening onto the face at the junction of the jugal, premaxilla and lachrymal is a large infraorbital foramen, the medial wall of which is formed by a prominent groove on the maxilla (visible in *S. ooliticus*).

The crown pattern of the upper postcanine teeth of these three genera differs from that of all other tritylodontids in having two cusps in each of three longitudinal rows, with very small accessory cuspules at the anterior end of each row. The crowns are oval in occlusal outline in *Bocatherium* and *Bienotheroides*, quadrangular in *Stereognathus*.

Knowledge of the extremely derived condition of the facial and palatal bones in these three genera permits the remaining genera known from adequate skull material to be arranged in a morphocline (Fig. 3). (*Tritylodontoideus*[6] is too poorly preserved to be included.) The most derived early Jurassic taxa are *Kayentatherium* (H.-D. Sues, unpublished) and *Lufengia* (J.A.H., unpublished), in which the premaxilla and palatine closely approach each other on the palate so that the maxillary component is greatly reduced. The premaxilla is in contact with the nasal in *Lufengia* juveniles (known adult skulls are damaged in this region) but not in *Kayentatherium* and other early Jurassic genera (Fig. 2*a*). The palatine of *Bienotherium* shows the primitive unexpanded condition, but the premaxilla extends well back

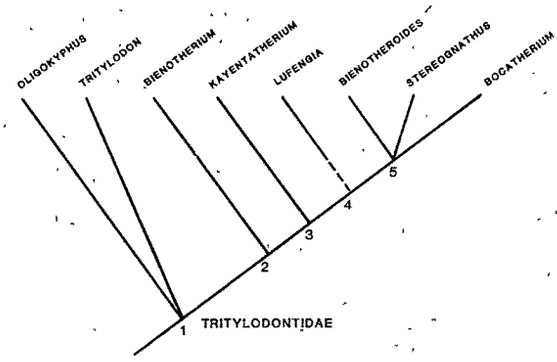

Fig. 4 Cladogram showing proposed relationships of tritylodontid genera. Synapomorphies for each node are as follows: 1, Second upper and first lower incisors enlarged; first upper incisor very small; canines absent; cheek teeth with divided roots; postcanines with three (upper) or two (lower) longitudinal rows of crescentic cusps; postorbital bar and prefrontal and postorbital bones absent. 2, Premaxilla extends further posteriorly on palate; snout relatively short with no post-incisive constriction. 3, Premaxilla extends posteriorly between anterior postcanines, and palatine extends anteriorly beyond level of palatine foramina so that palatine process of maxilla is reduced. 4, Premaxilla in contact with nasal, and facial process of maxilla reduced in area (in *Lufengia* juveniles; adult condition uncertain). 5, Facial, palatine and zygomatic processes of maxilla absent; upper cheek teeth with two principal cusps in each longitudinal row.

on the palate (J.A.H., unpublished). All of the above genera are similar in possessing the presumably derived condition of a short snout lacking a constriction behind the incisor region. *Tritylodon* (J.A.H., unpublished) and *Oligokyphus*[9] have a short premaxilla and a long narrow snout with a mid-length constriction; these features are found both in early mammals[21] and in gomphodont cynodonts (J.A.H., unpublished) and thus are considered primitive for tritylodontids. The interrelationships of tritylodontid genera (Fig. 4) suggest that a small number of cusps in the upper postcanine teeth is a derived condition.

The close relationship of *Bocatherium* to *Bienotheroides* and *Stereognathus* suggests that the Mexican form may also be post-early Jurassic in age; it is certainly younger than late Triassic. A Jurassic age for the upper part of the La Boca Formation is consistent with the stratigraphical[18] and palaeomagnetic[19] evidence. We believe *Bocatherium* to be the oldest terrestrial vertebrate known from Mexico. If the upper part of the La Boca Formation proves to be middle Jurassic in age, *Bocatherium* will be the first terrestrial vertebrate of this age in North America[22,23].

Neo-darwinian evolution implies punctuated equilibria

C. M. Newman*, J. E. Cohen†§ & C. Kipnis‡

The two central elements of neo-darwinian evolution[1,2] are small random variations and natural selection. In Wright's view, these lead to random drift of mean population characters in a fixed, multiply peaked 'adaptive landscape', with long periods spent near fitness peaks[3,4]. Using recent theoretical results[5], we show here that transitions between peaks are rapid and unidirectional even though (indeed, because) random variations are small and transitions initially require movement against selection. Thus, punctuated equilibrium[6,7], the palaeontological pattern[8,9] of rapid transitions between morphological equlibria, is a natural manifestation of the standard wrightian evolutionary theory and requires no special developmental, genetic or ecological mechanisms[10-13].

The simplest neo-darwinian model for the evolution of the population mean $\bar{x}$ of a genetically determined character expresses the change $d\bar{x}$ in time interval dt as the sum of a natural selection term and a random variation term:

$$d\bar{x}(t) = F'(\bar{x}(t)) + \alpha\, dW(t) \qquad (1)$$

$F(\bar{x})$, a one-dimensional genotypic[3] or phenotypic[14] adaptive landscape, describes the mean population fitness. If, for example, the slope F' is positive (a rising landscape) at $\bar{x}(t)$, natural selection pushes $\bar{x}$ towards larger values. The parameter α gives the magnitude of random variations relative to that of natural selection. The random process $W(t)$, a standard brownian movement with zero mean drift, represents, for example, genetic drift and short-term environmental fluctuations showing no obvious trend. We assume, for simplicity, that α is independent of $\bar{x}$.

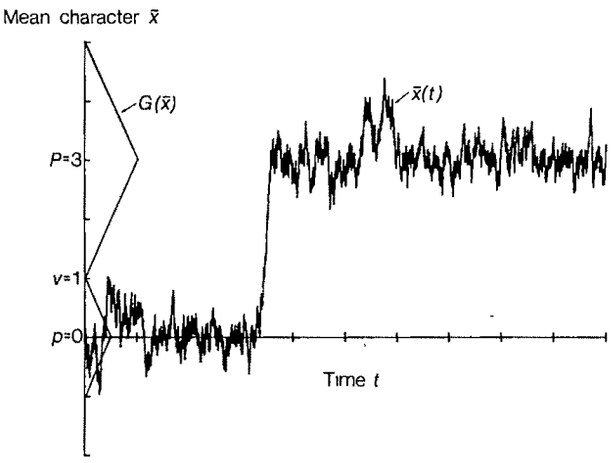

Fig. 1 Punctuated equilibria in a numerical solution of the discrete time equation, $\bar{x}(t+1) - \bar{x}(t) = G'(\bar{x}(t)) + sw_t$. The landscape G has a lower peak at $\bar{x}=0$, a valley at $\bar{x}=1$ and a higher peak at $\bar{x}=3$; its slope, G', takes only the values $+0.01$ or -0.01. w_t Represents the sign of random variables, s their magnitude. For each t, w_t is independently $+1$ or -1 with equal probability; $s=0.07$. The jagged line plots $\bar{x}(t)$ for 5,000 time units. As theory predicts, during the transition between peaks, $\bar{x}$ moves from 0 to 1 as if the direction of natural selection were reversed, that is, at the same speed that $\bar{x}$ moves by natural selection from 1 to 3.

Suppose that the landscape is doubly peaked: as $\bar{x}$ increases, F rises to a peak at $\bar{x}=p$, declines to a valley at $\bar{x}=v$, rises to a second higher peak at $\bar{x}=P$, then declines. Let the initial value $\bar{x}(0)$ be smaller than v. To mimic the fossil record, suppose $\bar{x}(t)$ is observed, not continuously, but at some finite (perhaps large) number N of epochs $0 < t_1 < \ldots < t_N$, perhaps chosen by another random process modelling stratigraphic sampling. There is a natural timescale τ_α associated with transitions from the smaller to the larger peak which increases dramatically as α decreases. We suppose that the intervals between observations are, for small values of α, proportional to τ_α.

Under these assumptions[5], for small α, the observed $\bar{x}(t_i)$ values behave quite differently from $\bar{x}(t)$ itself, which is intrinsically continuous. As α approaches 0, the observed values become fixed exactly at p for some random (exponentially distributed) time, then jump (apparently) instantaneously to P

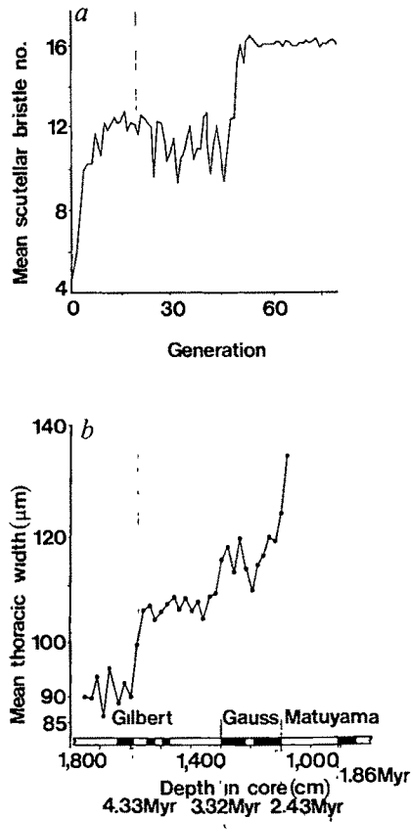

Fig. 2 *a*, Response to selection for scutellar bristle number in female *Drosophila* (presumably *melanogaster*; species not given[16]) according to MacBean *et al.*[16], as simplified by Parsons[18]. *b*, Increase in thoracic width of the Antarctic radiolarian *Pseudocubus vema* during ~2.5 Myr according to Kellogg[17], as simplified by Parsons[18]

and remain there (apparently) indefinitely. Analogous results hold if F has more than two peaks[5] or if $\bar{x}$ is multidimensional[15].

To understand this result, note that a movement of $\bar{x}$ from p to v goes against the influence of natural selection and, for small α, is very improbable. Improbable events eventually occur (with timescale τ_α) and then by the most likely of the improbable alternatives. Here it is most likely[5] that small random variations combine to push $\bar{x}$ from p to v as if the direction of natural selection were reversed, hence rapidly and unidirectionally. Once at v, the move to P is by natural selection. The rapidity of the second part of the transition is well recognized[4], whereas that of the first part seems largely unknown.

Figure 1 is a computer simulation illustrating the theoretical results about equation (1). For comparison, Fig. 2 shows examples[16,17] (from ref. 18) of observed punctuated equilibria with two different timescales.

In a changing landscape, punctuation can be triggered by selection, rather than drift, either by a rapid (for example, environmental) change[19] or after a gradual change eliminates the currently occupied peak[13]. The introduction of a rare selectively superior mutant into a population from which it was previously absent can lead to punctuation[20,21] corresponding to transition from an unstable equilibrium in a fixed landscape. Our analysis is the first to show that transitions between stable equilibria, triggered by drift in an unchanging adaptive landscape, should have fossil records indistinguishable from punctuations triggered by selection.

Gradual evolution is only possible in an unchanging landscape either if α is not small (violating neo-darwinian assumptions) or if sampling intervals are as short as the timescale of natural selection (unusual in fossil records). Even assuming many peaks, the suggestion[20,22] that stepwise changes will appear to be gradual on a coarse timescale seems to be inconsistent with Wright's model: an increased timescale of observation implies[5] that more local peaks are skipped over apparently instantaneously and stasis is observed only at higher fitness levels.

Gradual evolution is possible in a changing landscape if peaks shift gradually and unidirectionally. Our analysis suggests a resulting palaeontological pattern of 'punctuated shifting equilibria' as the gradual evolution of a population following a moving peak is punctuated by rapid transitions between peaks. It is unclear whether such changing landscapes should occur commonly.

Models similar to that described in equation (1) are applicable directly to populations that are panmictic or have much migration and hence are geographically homogeneous. Because the timescale τ_α is a rapidly increasing function of population size, equation (1) predicts stasis and punctuation for a small to moderate population but only stasis for a large population.

The model in equation (1) may be applied to an isolated subpopulation with a smaller τ_α than the larger parent population. Allopatric speciation will occur if the subpopulation, after transition to a new peak, cannot interbreed with the parent population. Without requiring special 'genetic revolutions',[23] our analysis predicts that punctuated equilibria will be associated with the branching speciation of isolated subpopulations.

Generalizations of equation (1) incorporating spatial inhomogeneity in a local mean character correspond to Wright's notion of local populations in his shifting balance model[3,4], in which he suggested that speciation could occur without physical barriers to migration and gene flow[23]. Mathematically non-rigorous[24,25] and rigorous[26] results suggest that punctuation occurs on the timescale τ needed to form by random drift (against natural selection) a 'critical droplet' (that is[23], a geographical region where transition to a higher peak of fitness occurs) which is of sufficient size to resist swamping by gene flow; such a critical droplet spreads rapidly by selection. The timescale τ is a slowly decreasing function of population size[27] (for fixed spatial density) because a critical droplet can form in each local subrange[4,23]. Unlike τ_α, this τ need not exceed geological timescales even for very large populations.

Interpolation in stereoscopic matching

G. J. Mitchison* & S. P. McKee†

* MRC Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH and Kenneth Craik Laboratory, Department of Physiology, University of Cambridge, Cambridge CB2 3EG, UK
† Smith-Kettlewell Institute for Visual Sciences, 2232 Webster Street, San Francisco, California, USA

Anyone who has stared at a repeating wallpaper pattern, or a periodic pattern of tiles, has probably experienced the phenomenon of a false stereoscopic depth percept. This arises because of a mismatching in the two eyes of repeating elements in the pattern. The phenomenon is less likely to occur if an edge of the textured region is in view; the edge seems to fix the registration of elements. We describe here a stereogram which exemplifies this principle; it has a central, periodic region bounded on either side by edges with pre-assigned disparities. We find that the perceived depth of the central region is controlled by the edges. In certain conditions (when the period is spatially large), the edges simply impose one of the expected discrete matchings. In other conditions, however, we observe a striking phenomenon: interpolation in depth occurs between the edges, violating any possible feature-by-feature matching.

Our stereogram can be broadly described as a regular grid of points with horizontal disparities introduced at the two vertical edges (Fig. 1*A*). A single row of the grid is shown in Fig. 1*B*, where the convention is that the vertical alignment of the dots seen by the left and right eyes corresponds to the zero disparity; that is, if each dot were matched to that vertically above or below, they would be seen in the fixation plane. The row consists of a set of equally spaced dots, typically 6 arc min apart, but with the left-most dot moved inwards a certain fraction, S_L, of the inter-dot spacing in the left eye, and the right-most dot moved inwards by a fraction S_R of the inter-dot spacing in the right eye.

The stereoscopic percept depends on how points in the two eyes are matched. When the stereogram is inspected carefully, using a large inter-dot spacing (for example, Fig. 2 viewed close up), one of two possible percepts is seen, depending on the size of S_L and S_R. When S_L and S_R are small, the percept corresponds to the matching shown in Fig. 1*C*(1), and consists of a plane with two flaps tilted forwards at the edges [Fig. 1*D*(1)]. When S_L and S_R are large, the underlying matching is that of Fig. 1*C*(2), in which each point is paired obliquely; the percept here is of a grid lying in front of the fixation plane, with two unpaired points at the edges [Fig. 1*D*(2)]. Thus, changing S_L and S_R causes a change of matching throughout the central regular lattice. Such propagation of matching from a limited area throughout a periodic region has been shown to occur in stereograms studied by Julesz and Chang[1], of which ours can be regarded as a highly specialized case.

To explore the depth percepts more systematically, we added a test point beneath the grid (Fig. 1*A*) and asked subjects, in a forced-choice paradigm, to judge whether the test point lay in front of, or behind, the grid. The test point was placed at a fixed vertical position below the grid, and could be given any desired horizontal location, so that depths of particular regions of the grid could be explored. The test point was randomly given one of seven equally spaced disparities, chosen so that at one extreme the grid lay considerably in front of the test point, and at the other, behind it. By fitting a cumulative gaussian curve to the percentage of trials on which the grid was reported as lying in front of the test point, we could locate the apparent mean position of the region of the grid above the test point, and also determine the standard deviation in its perceived position[2]. Observers were first shown a fixation pattern which disappeared during the subsequent 160-ms presentation of the grid and test point.

When the (horizontal) inter-dot spacing in the central region was >6–8 arc min, we found that the grid lay either in the fixation plane [as expected according to Fig. 1*C*(1)], or moved forward to the depth expected of the oblique matching in Fig. 1*C*(2). The former was seen when the sum of the displacements, $S_L + S_R$, was small (<1 inter-dot spacing), and the latter when the sum was large (>1.5 inter-dot spacing). For intermediate values of the sum $S_L + S_R$, either depth percept might be seen on a given trial, with a probability depending on the sum $S_L + S_R$.

A radically different type of behaviour was seen when the inter-dot spacing was <6 arc min; it was then possible to obtain depth percepts which could not be accounted for by any discrete matching of points. For example, Fig. 3*A* shows a depth profile of a grid with $S = 0.2$, $S_R = 0.8$. This profile is slanted in depth: it runs continuously between the depths which would be expected from matching the end points (open circles), and none of the intermediate values is compatible with discrete pairings of points within the grid. It is as though the end points have been paired and the intermediate depths obtained by interpolation between these extremes. For comparison, Fig. 3*A* also shows profiles for $S_L = S_R = 0$ and $S_L = S_R = 0.67$; both of these are

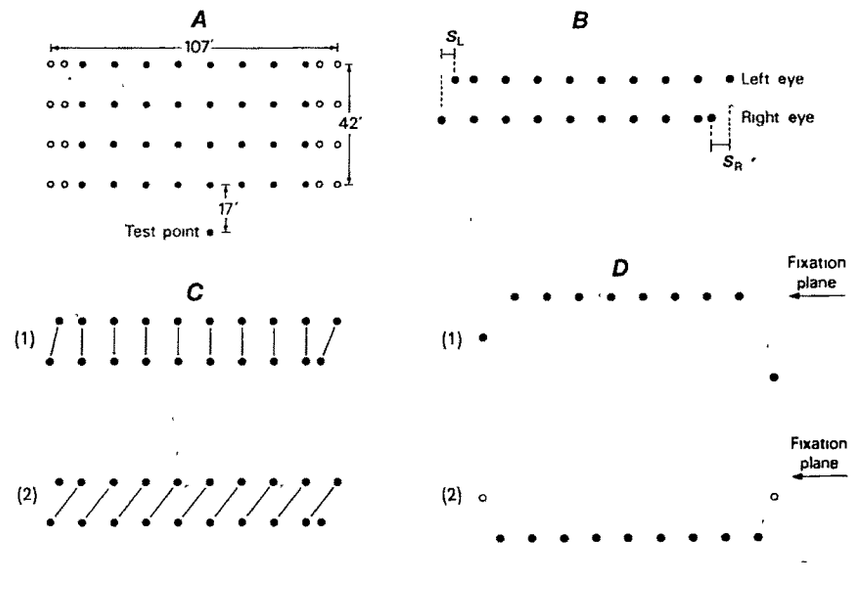

Fig. 1 *A*, The grid of our stereogram, showing the test dot. *B*, A single row from the grid, with the left-most dot in the left eye displaced inwards by a fraction S_L, and the right-most dot of the right eye displaced by a fraction S_R of the inter-dot spacing *C*, (1), (2), Two possible matchings of points of the left and right eyes in a single row. In (1) the dots are matched in sequence; in (2) the displaced dots at the ends of each eye's row are unmatched, and a point in the left eye is matched to a point in the right eye which is one step of the grid to its left. *D*, The depth percepts expected, based on conventional stereoscopic theory, from the matchings (1) and (2). The fixation plane (vertical matching in *C*) is indicated by an arrow In fact, a fixation target was always presented before the grid was shown, but was never shown simultaneously with it. In (1), two dots lie in front of the fixation plane. Here S_L is shown smaller than S_R, so the right-most dot should be farther in front than the left-most. In (2) the grid lies in front of the fixation plane (corresponding to a crossed disparity). The two monocular points (open circles) appear to lie behind the grid, although we do not know precisely what perceived depth should be assigned to them.

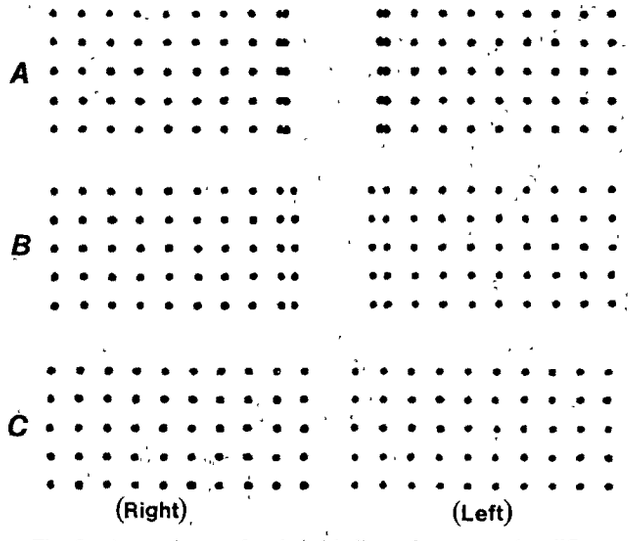

Fig. 2 A stereogram of grids (with dimensions somewhat different from those in Fig. 1*A*) to show the basic phenomena. The displacements S_L and S_R are equal: they have a large value in panel *A* and are zero in *C*. In *B*, a displacement has been chosen which should give an intermediate depth percept under interpolation conditions. Those who free-fuse by converging will see the grid correctly; those who diverge will see the depths reversed. When the stereogram is viewed quite close up (say 1 m), the discrete matchings of Fig. 1*C* and *D* should be seen. When it is viewed from a distance of ≥3 m, the inter-dot spacing comes within the interpolation range (<6 arc min), and *B* should appear at a depth between that of *A* and *C*.

flat, the former being close to the fixation plane, and the latter forward of it, though not as far forward as would be expected for the oblique matching.

These intermediate-depth percepts do not correspond to an ambiguous alternation between the two matchings, as demonstrated by the curves showing the proportion of trials in which the test dot lay in front of the grid, as a function of test dot disparity (Fig. 3*B*). If there were an alternation of percepts, these curves would be broad, encompassing the range from the fixation plane to the forward matching. However, they are very narrow, having a standard deviation of 10–15 arc s. The intermediate depths (such as curves *b–d* in Fig. 3*B*) are, in fact, as well localized as the extremes (curves *a*, *e*) which satisfy a 'conventional' matching. Depth percepts which lie between possible discrete matches have been described by Foley[3], and may be related to those we find, but his conditions were very different from ours, and the intermediate states far less localized.

Interpolation appears to be quite stable under prolonged inspection (for example, Fig. 2 viewed at ≥3 m), and, in particular, the percept does not depend on vergence. The viewing time of 160 ms used in our experiments was designed to eliminate changes of vergence during each presentation. In one experimental condition, the displacements *S* were changed randomly from trial to trial to prevent the observer from maintaining a biased convergence position in front of the fixation plane, and essentially similar results were obtained.

One might attempt to account for interpolation by saying that the stereo matching system has a coarser resolution than 6 arc min, and 'sees' only the ends of the grid when the inter-dot spacing is small. We can show that this is not the case by randomly perturbing points in the periodic region by the same amount in each eye; when this is done, the grid can be matched as a flat surface in the fixation plane (Fig. 4*A*), but the oblique matching should introduce disparity variations (Fig. 4*B*). There are general arguments for expecting that the matching which gives the more continuous depth profile will be preferred[4] and, indeed, even quite small random perturbations keep the grid in the fixation plane matching Fig. 4*A*, no matter how large the displacements *S*. For example, for an inter-dot spacing of 3.7 arc min, a 20-arc s (SM) or 40-arc s (GM) perturbation serves to

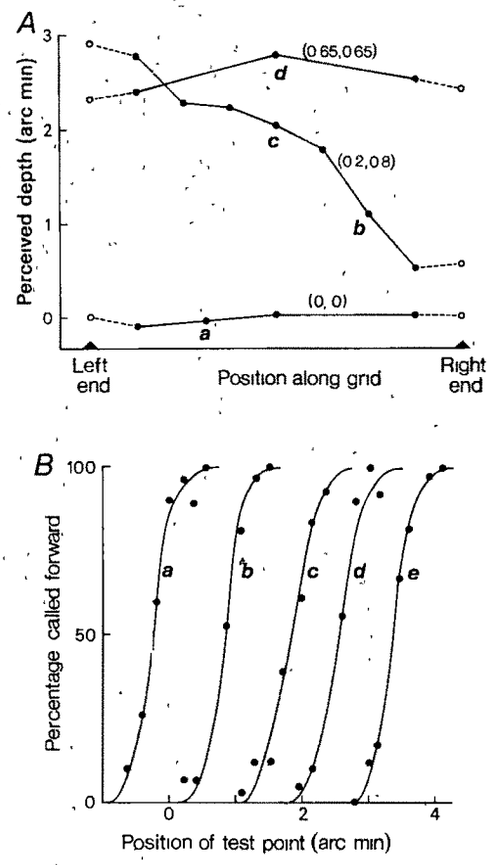

Fig. 3 *A*, Apparent depths for various values of S_L and S_R (shown in brackets) at selected positions along a grid of inter-dot spacing 3.7 arc min (test subject G J.M.). Each solid point represents the mean of a psychometric curve (see *B*) based on at least 200 trials. The open circles show the expected depths of the paired end points of the grid, calculated from their disparities. *B*, Psychometric functions for various points in *A* (curves *a–d*) and for the grid with $S_L = S_R = 1$ (*e*). The ordinate shows, for a given disparity of the test dot, the percentage of responses 'test dot in front of grid'. If a cumulative gaussian is fitted to these points using the probit method[2], its mean defines the apparent depth of the grid, and its standard deviation indicates the imprecision of this depth judgement

keep the grid in the fixation plane, even with the largest possible values of S_L and S_R. Stereoscopic matching is therefore sensitive to very small perturbations of the points in the grid.

What is the relationship between interpolation and the conventional point-by-point matching seen for larger dot spacings? To determine how they interact, we constructed a grid which expands slowly so that the spacing in the centre is in the range where discrete matching occurs, while the spacing at the edges lies well in the interpolation range (Fig. 4*C*). A displacement at the edges brings forward the whole grid, generating a vivid arch in depth. This implies that interpolation is not merely an interpretative stage which supplies appropriate depths after matching is complete, but can influence matches, as in the central region here.

We have seen that the edges of the grid have a privileged role in that they provide end points for interpolation. What counts as an edge? If we displace two dots in the centre of our grid, so making a small gap, the resulting percept exhibits two segments of interpolation (Fig. 4*D*), suggesting that the inner gap provides two 'edges' in this sense (dotted lines).

In summary, the stereo matching system appears to skip over regions with a periodic spacing of <6 arc min, but is alert to small irregularities within such a region. These irregularities might be interpreted either as gaps or as disparity discontinuities. Of the two possibilities, the second is the more attractive; it implies that it is not periodicity *per se* which is required for

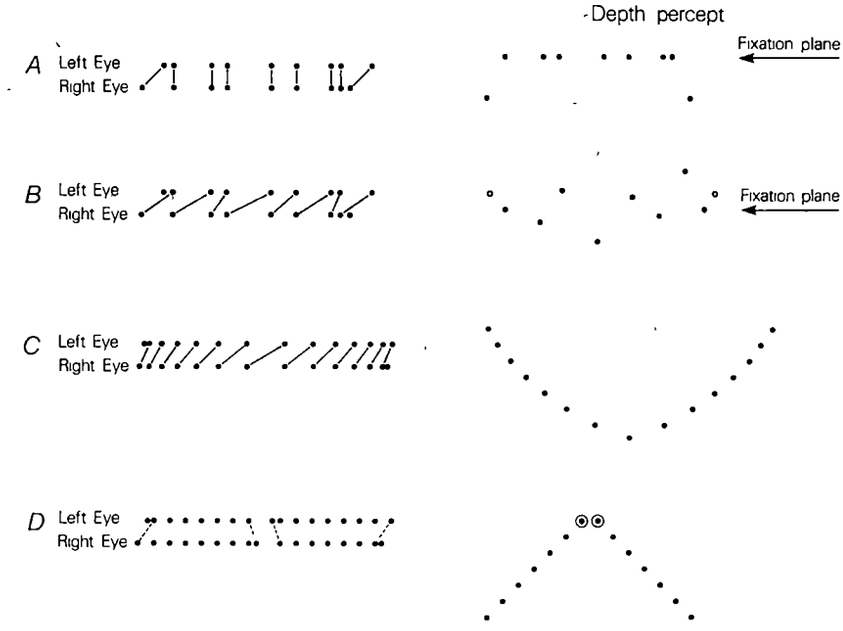

Fig. 4 *A*, In a modified version of the stereogram, a grid is constructed from several identical rows such as that shown here This row is derived from that shown in Fig 1*B* by leaving the outer two dots in each eye unchanged, but randomly perturbing the inner dots by the same amount in each eye. The lines show the matching which corresponds to Fig. 1*C*(1), and the depth percept is shown to the right. This is found for all dot spacings in the interpolation range (<6 arc min). *B*, An oblique matching, corresponding to Fig. 1*C*(2), in which each dot in the left eye is matched with a dot one further along in sequence in the right eye; this generates a ragged depth profile (shown on right) *C*, A modified version of the row shown in Fig. 1*B*. The spacing between dots at the edges is 3 arc min; this spacing increases gradually towards the centre, reaching a maximum of 11 arc min, and then decreases again, in a symmetrical fashion. The expected depth percept for the oblique matching shown is a forward-bending arch. *D*, A gap is created by displacing two dots near to the centre of the grid. In the left eye, a dot is moved half an inter-dot spacing to the right; in the right eye, the dot which would be paired with this in the fixation plane is moved to the left by the same amount. With the dot spacing in the interpolation range, two segments of interpolation are seen (shown on right). The fine broken lines indicate the matching which defines the 'edge' In fact, the perceived depth of these dots is somewhat variable between trials, and this is indicated by ringing of the dots in the diagram of the depth percept

interpolation, but simply the absence of disparity discontinuities. There is an obvious economy in making explicit matches only where a potential disparity discontinuity is registered.

These findings impose some constraints on models of stereoscopic matching. For example, the fact that disparities at the edges determine the matching within each grid in the absence of vergence movements argues against the coarse-to-fine vergence strategy postulated by Marr and Poggio[5]. Information might, in principle, be propagated inwards from the edges by a cooperative process of point-by-point matching[4,6], but it seems unlikely that such a mechanism operates under interpolation conditions.

Changes in the dendritic branching of adult mammalian neurones revealed by repeated imaging *in situ*

Dale Purves & Robert D. Hadley

Department of Anatomy and Neurobiology, Washington University School of Medicine, 660 South Euclid Avenue, St Louis, Missouri 63110, USA

A major obstacle to understanding the mechanism of long-term change in the vertebrate nervous system has been the inability to observe the same nerve cell at different times during the life of an animal. The possibility that changes in neural connectivity underlie the remarkable flexibility of the nervous systems of mammals has therefore not been tested by direct observation. Here, we report studies in which we have visualized the same neurone in the superior cervical ganglion of young adult mice at intervals of up to 33 days. This collection of nerve cells is particularly accessible and therefore well suited to our approach. We find that the dendritic branches of the neurones examined change appreciably over intervals of 2 weeks or more; some branches retract, others elongate and others seem to form *de novo*. The apparent remodelling of these postsynaptic elements implies that the synaptic connections of these cells normally undergo significant rearrangement beyond what is usually considered to be the developmental period.

Sexually mature male mice (8-12 weeks old, 25-35 g, CF1 strain) were anaesthetized with chloral hydrate and mounted on a platform that could be moved in three axes for positioning and focusing. Either the right or the left superior cervical ganglion was exposed through a midline incision, care being taken to preserve the blood supply. The wound was superfused with sterile lactated Ringer's solution (Travenol) and the pool of fluid grounded with a chloride-treated silver wire. The ganglion surface was illuminated at an oblique angle by a plastic light guide (diameter 0.7 mm). Proper adjustment of the angle of illumination caused the neurones on the surface of the ganglion to appear as a mosaic of polygonal cell outlines (Fig. 1*a*). Individual neurones could be identified as a result of variations in size, shape, neighbour relationships and position with respect to blood vessels. A particular nerve cell was selected for study and 35-mm colour transparencies were taken of the relevant region of the ganglionic surface at a magnification of ×35-320. Following photography, the neurone that had been selected was impaled under direct vision at a magnification of ×125 with a microelectrode filled with a 6% solution of 5(6)-carboxyfluorescein in 0.44 M KOH (*p*H 7.0; resistance 80-150 MΩ). Resting potentials usually ranged from −40 to −60 mV; all cells had overshooting action potentials, occurring either spontaneously or elicited by current injection through the microelectrode. The illuminator was then turned off and the dye injected iontophoretically by passing hyperpolarizing current for 2 min (3-4 nA d.c.). Subsequent observations of the cell were made on a video monitor with a low-light level video camera (GE model 4TE56 SIT) and a ×40 water-immersion lens with a

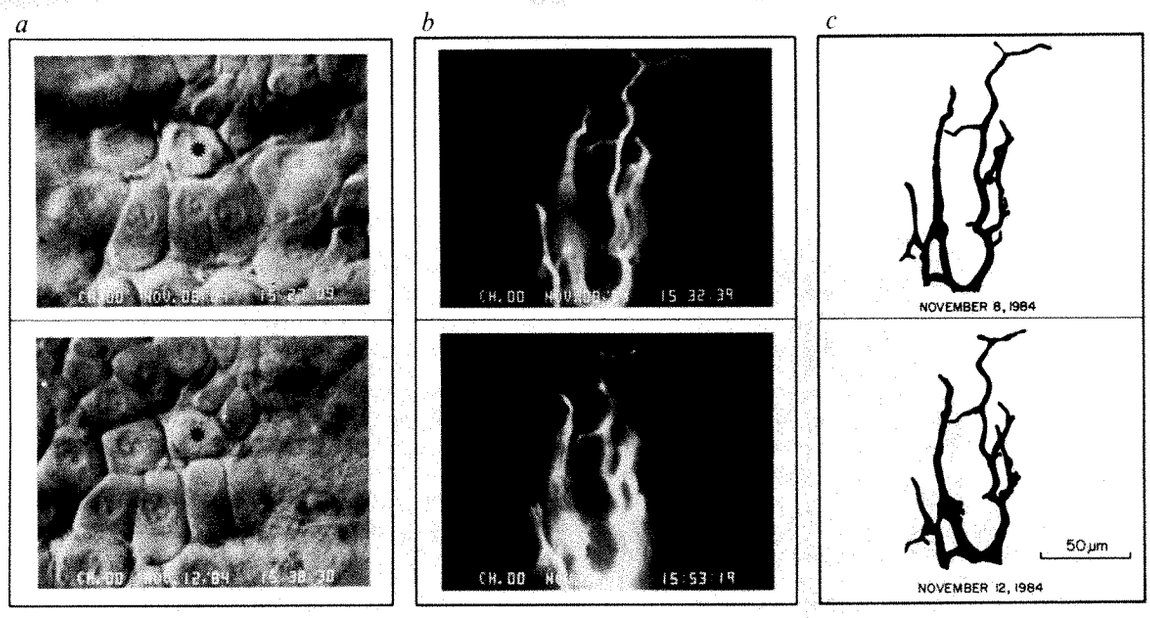

Fig. 1 Identification and imaging of the same neurone over a 4-day interval. *a*, Surface images of a mouse superior cervical ganglion. The same ganglion cells could be recognized at a second operation by virtue of their size, position and relationship to other landmarks such as blood vessels. The neurone marked with an asterisk was impaled with a microelectrode and injected with 5(6)-carboxyfluorescein on both days (see text). *b*, Fluorescent images of a portion of the dendritic arborization of the injected cell in comparable focal planes (this and subsequent photographs were taken from a video monitor). Parts of several large dendrites and their higher-order branches can be seen; the cell soma is just below the bottom of the frame. *c*, Five to ten images at slightly different planes-of-focus were combined to form reconstructions such as those shown here. Comparison of the initial and final images of this and other neurones observed at intervals of a few days showed relatively little change (see Table 1).

numerical aperture of 0.75 and a working distance of 1.6 mm. The dye-filled cell was imaged using standard epifluorescence optics (390–490 nm excitation, 515 nm suppression); low-level illumination was provided by a 6-V, 15-W tungsten bulb controlled by a rheostat and focused through a heat filter. After verifying that the intended cell had been successfully injected, a portion of its dendritic arborization, usually one primary dendrite and its branches, was chosen for study. Fluorescent images were recorded on Polaroid film (Fig. 1*b*). We photographed only a part of the dendritic arborization of each cell to minimize the time of exposure of the cell to the exciting wavelengths. The total period of exposure of the neurone to the exciting light was <1 min. After satisfactory pictures had been obtained the wound was closed and the animal was allowed to recover. The entire procedure usually took ~1 h.

Following an interval of 3–33 days, the animals were re-anaesthetized and the ganglion exposed as before. Projection of the transparencies made at the initial operation allowed us to identify the neurone that had been impaled previously. The cell was re-impaled and injected with dye in exactly the same manner as at the first operation (the dye is lost from the cell within a few hours). Comparisons of dendritic geometry were made either from single focal planes (Fig. 1*b*) or by reconstructing the relevant portion of the dendritic arborization from 5–10 photographs taken at slightly different depths of focus (Fig. 1*c*).

Single neurones from a total of 57 mice were examined by this method. In 44 of these animals we were successful at the second operation in identifying the portion of the ganglionic surface that had been studied previously. In the other 13 animals we were unable to locate the appropriate region; most of these failures occurred near the beginning of our series of experiments when we were less experienced at choosing locations and cell groupings that would be easy to identify subsequently. In 28 of the 44 animals in which the correct region was located, the cell of interest was identified and successfully re-impaled. Average resting potential and action potential amplitudes were not appreciably different from values obtained at the initial operation. In the 16 remaining cases the neighbouring cells could be identified but the cell of interest apparently had died and been removed by phagocytic action. Thus the survival rate of neurones impaled and imaged in this way was ~64%. The death of about a third of the neurones is not explained by illumination of the fluorescent dye, because in additional control experiments 4 out of 10 cells that were filled with dye but never illuminated also died. The fluorescent dye itself has been shown to be non-toxic in at least one other neural system[1], although prolonged or intense exposure to the exciting wavelength can kill dye-filled cells[2]. Therefore, it seems likely that impalement by a microelectrode is sufficient to cause the death of some cells.

The dendritic arborizations of neurones observed in this way showed shape changes that were, in general, proportional to the

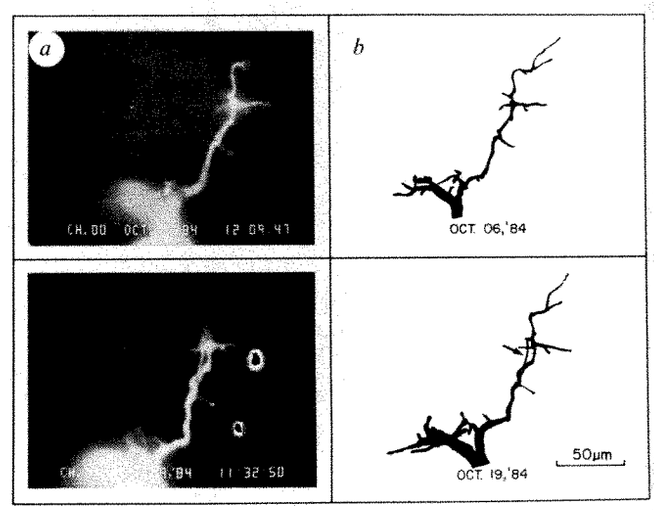

Fig. 2 Images of a neurone observed at an interval of 13 days. *a*, Fluorescent images of an identified neurone at the beginning and end of the period of observation; the plane of focus is approximately the same in both images. *b*, Reconstructions of this portion of the dendritic arborization of the neurone from six different focal planes at the beginning and end of the interval. Examination of higher-order branches showed changes that were more obvious than those observed at shorter intervals; for example, the branch marked by the arrow seems to have formed *de novo* about halfway along the major dendrite.

Table 1 Dendritic changes of mouse superior cervical ganglion cells over intervals of 3–33 days

Interval (days)	No. of cells studied	No. of branches unchanged	No. of branches extended	No. of branches retracted	Branches changed (%)
3–8	4	17	0	0	0
13–14	3	11	4	3	39
28–33	6	9	8	10	67

The classification of a branch as having extended, retracted or remained unchanged is based on an apparent change of >10 μm; measurements were made from camera lucida drawings (see Figs 1–3) using a digitizing pad attached to a computer. Only terminal dendritic branches reconstructed completely from multiple focal planes were included (13 of the 28 cells imaged at two different times).

interval between observations. Although the images obtained at the two different times were never exactly congruent (in part because of small differences in rotation and variations in the tension on the cell), the general configuration of the processes that had been viewed initially was easily recognized and always had the same overall arrangement. Thus, dye filling was complete, or at least consistent in what it revealed. Detailed examination showed differences in the dendritic geometry of many cells, involving the retraction of some branches and the extension of others. In some instances branches evident during the initial observation of the cell had disappeared altogether, whereas other dendritic branches appeared *de novo* in this interval. In most cases, the changes observed at longer intervals were more extensive than those observed at shorter intervals.

Thus, eight neurones that were visualized at intervals of 3–8 days showed relatively minor changes (Fig. 1). The 13 neurones that were imaged after 13–16 days often showed more obvious changes (Fig. 2). In seven animals the same cell was imaged after an interval of 28–33 days. Although the general configuration of the dendrites at the second viewing could still be recognized as similar to the initial pattern, in each case the changes were more extensive than those observed at the shorter intervals (Fig. 3; Table 1). Complete reconstructions of the relevant portion of the dendritic arborization were made in 13 of the 28 cells studied. To quantitate this progressive change, individual branches were measured and scored according to whether they had changed by more than 10 μm (see Table 1).

Our results show that the dendrites of the cells observed gradually change over periods of a few weeks. We cannot eliminate the possibility that such changes represent a response to the experimental procedure rather than normal remodelling of dendritic arborizations. However, two aspects of our results provide evidence against artificially induced changes in cell shape. First, the surviving cells remained healthy; resting potential and action potential amplitudes of the cells at the second observation were indistinguishable, on average, from values obtained during the initial impalement, and the dendritic arborizations, although changed, were normal in appearance. Second, and perhaps more importantly, the dendritic arborizations changed progressively over the period of observation (up to 33 days) (Table 1). Although the procedure used here might have caused some initial damage, it seems unlikely that such an effect would continue to contribute to the loss and gain of dendritic processes weeks later.

Our interpretation of these observations is that extension and retraction of dendritic processes is a normal occurrence in sympathetic ganglia of young adult mammals. As most synapses on superior cervical ganglion cells in the mouse are made on dendritic processes (ref. 3 and C. J. Forehand, unpublished observations), the dendritic changes we describe are presumably accompanied by commensurate changes in the synaptic connections of these neurones. It will be of interest to examine neurones in other parts of the nervous system where this same general approach may be feasible.

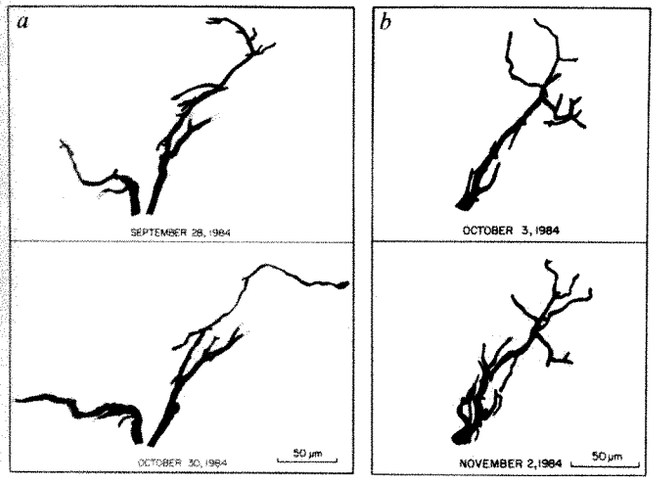

Fig. 3 Reconstruction of a portion of the dendritic arborizations of two ganglion cells observed after an interval of 1 month. *a*, A dendrite with several branches has withdrawn, whereas another branch has apparently extended more than 50 μm. Dashed lines indicate continuance of some branches to deeper levels that were not photographed. *b*, Similar retraction and extension of particular branches. Changes observed after 28–33 days were more prevalent and extensive than those observed at shorter intervals (compare Figs 1, 2; see also Table 1).

Axon guidance in cultured epithelial fragments of *Drosophila* wing

Seth S. Blair, Marjorie A. Murray & John Palka

Department of Zoology, University of Washington, Seattle, Washington 98195, USA

Growing axons can be guided by a number of different cues: adhesive substrates[1,2], diffusible factors[1–3], electrical fields[1,2,4] and even factors intrinsic to the neurone itself[1,2,5] have all been shown to affect axon orientation and outgrowth *in vitro*. However, in most intact systems it has proved difficult to test directly the role played by these putative guidance cues. Here, we describe a system, the developing wing of the fruitfly, in which we have tested simultaneously two putative guidance mechanisms, physical constraints to axon growth (channels) and the position of neuronal somata (guideposts), using surgical techniques. We show that pioneer sensory axons can navigate correctly and form their normal stereotyped pattern of axon bundles in wing fragments that apparently lack both physical and neural cues. This technique allows access to the surface along which neuronal pathfinding takes place, making possible a wide range of experimental manipulations on the developing system.

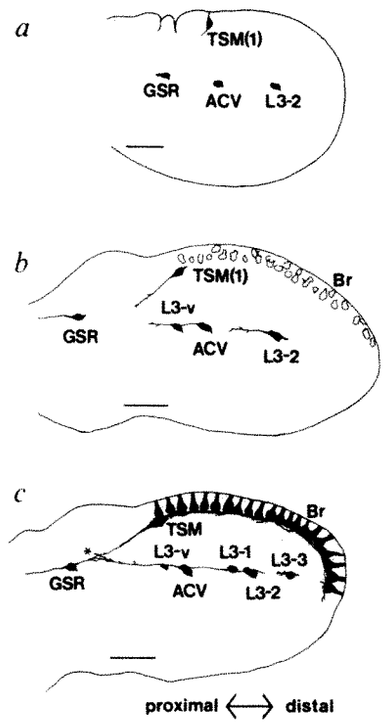

Fig. 1 Sensory neurones of a wing at 2 h after pupariation (*a*), or after having been removed at 2 h after pupariation and cultured for an additional 8 h (*b*) or 22 h (*c*). The earliest-arising neurones are those of the anterior cross vein campaniform sensillum (ACV), the second dorsal campaniform sensillum of the third vein (L3-2), the first twin campaniform sensillum (TSM(1)) and the giant campaniform sensillum of the radius (GSR); these neurones initiate axonogenesis just before (TSM(1) and GSR) or just after (ACV and L3-2) 2 h after pupariation. The ACV, L3-2 and TSM(1) neurones are each accompanied by an 'extra' neurone, E-1, E-2 and E-T respectively, which seem to develop similarly to the sensory neurones[8]; each of these cell pairs will be treated as a single unit designated by the name of the sensillum. Later-arising neurones initiate outgrowth at about the same times *in vivo* and *in vitro*, the ventral campaniform sensillum (L3-v) neurone at 5 h after pupariation, and the neurones of the first and third dorsal campaniform sensilla of the third vein (L3-1 and L3-3) and of the bristle sensilla (Br) at 12 h after pupariation[8,14]. Axon outgrowth is slightly slowed but essentially normal *in vitro*[14], although axons often fail to grow proximally beyond the junction of the first and third veins (asterisk; see text) after 22 h *in vitro*. Wings were cultured in Shields and Sang M3 medium supplemented with 10% fetal bovine serum[25] as described previously[14], except for the addition of 250 U ml^{-1} penicillin, 250 $\mu g\ ml^{-1}$ streptomycin, 0.63 $\mu g\ ml^{-1}$ Fungizone (Gibco) and 50 $\mu g\ ml^{-1}$ tetracycline-HCl (Sigma), and the exclusion of β-ecdysone from the medium. Distal is to the right. Scale bars, 50 μm.

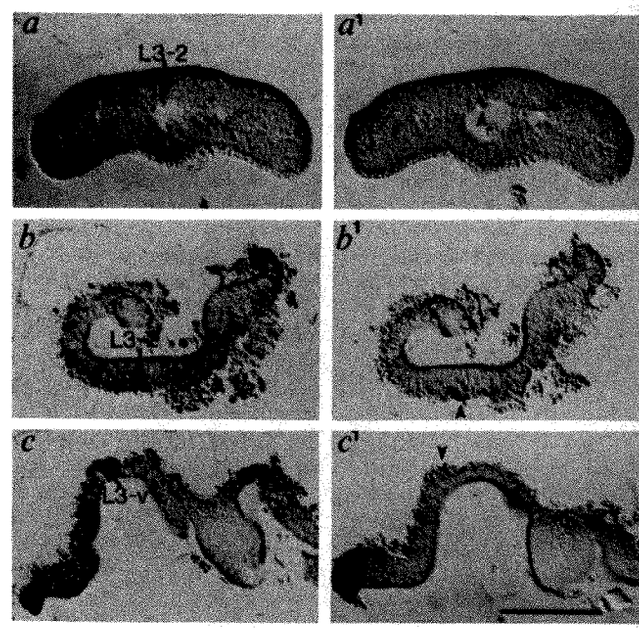

Fig. 2 Transverse sections through wings that had been removed at 2 h after pupariation and cultured an additional 8 h. Neurones were stained with anti-horseradish peroxidase (HRP) and an HRP-conjugated second antibody, and appear dark because of the HRP reaction product. *a*, a^1, Adjacent sections from a whole cultured wing, showing channels and the position of the soma of the L3-2 neurone (*a*) and axon (a^1, arrow) within the most central of them. *b*, b^1, Adjacent sections from a dorsal fragment generated at 2 h after pupariation, showing the position of the L3-2 soma (*b*) and axon (b^1, arrow); note the lack of channels or folds along the path of axonal outgrowth. *c*, c^1, Adjacent sections from a ventral fragment, showing the position of the soma of the L3-v neurone (*c*) and short axon (c^1, arrowhead); this fragment similarly lacks channels or folds along the path of axonal outgrowth. Three or more of each type of fragment (dorsal and ventral) have been completely sectioned; none shows any type of morphological irregularity which might act to guide growing axons in the distal wing blade. Fragmented wings for sectioning were reared and fixed after having been pinned flat onto Sylgard using glass needles; this reduces curling of the wings and does not affect axon guidance (8 h dorsal fragments, 6 of 6 cases). Wings were fixed and stained with anti-HRP as described previously[8], except that HRP-labelled goat anti-rabbit IgG (Cappel) was used as the second antibody, reacted with diaminobenzidine, cleared in 80% glycerol, embedded in JB-4 plastic, sectioned at 5 μm (in some cases (not shown) counterstained with toluidine blue) and viewed using Nomarski optics. Scale bar, 50 μm.

The wing of the fruitfly *Drosophila melanogaster* develops from an epithelial sac, the wing imaginal disk. During early stages of metamorphosis, the disk everts and flattens, bringing together originally separate epithelia to form the dorsal and ventral surfaces of the flat wing blade. Gaps are formed between the apposed inner epithelial surfaces, so that by 4 h after pupariation a system of channels loosely corresponding to the pattern of venation of the adult wing is created[6–8]. These channels are transiently lost when the wing inflates between 12 and 24 h after pupariation.[6,7] The pioneer sensory neurones of the wing (the neurones of specific large campaniform sensilla) are born (before 0 h after pupariation, from epithelial mother cells), differentiate (0–2 h after pupariation), initiate axonal outgrowth (1–3 h after pupariation) and complete the basic scaffolding of nerve bundles (12 h after pupariation) before this time[8,9] (Fig. 1). Thus, the first axons navigate through a system of channels between apposed epithelial cells, which might act to limit and guide axonal outgrowth. A similar role has been proposed for channels in the developing vertebrate central nervous system[10] and retina[11].

To test this hypothesis, the formation of channels between the wing epithelia was prevented by cutting the wing disk into dorsal and ventral fragments, after eversion but before the apposition of the two surfaces (2 h after pupariation); channels in such fragments could no longer be closed because the opposite epithelium was lacking. Axon outgrowth was assessed by rearing the fragments in culture for a further 8 or 22 h and then staining their neurones with antiserum generated against horseradish peroxidase[12]. No closed channels were observed in epithelial fragments cultured for 8 h; axons grew along the innermost surface of the epithelium and did not seem to be following any histologically detectable morphological irregularities, such as grooves or folds (Fig. 2). This technique therefore allowed us to analyse the pathfinding abilities of axons growing in a channel-free environment.

As demonstrated previously[13,14], whole wing disks reared *in vitro* show largely normal patterns of axonal outgrowth (Fig. 1). Neurones in dorsal and ventral wing fragments differed somewhat in their ability to reproduce this normal pattern[15].

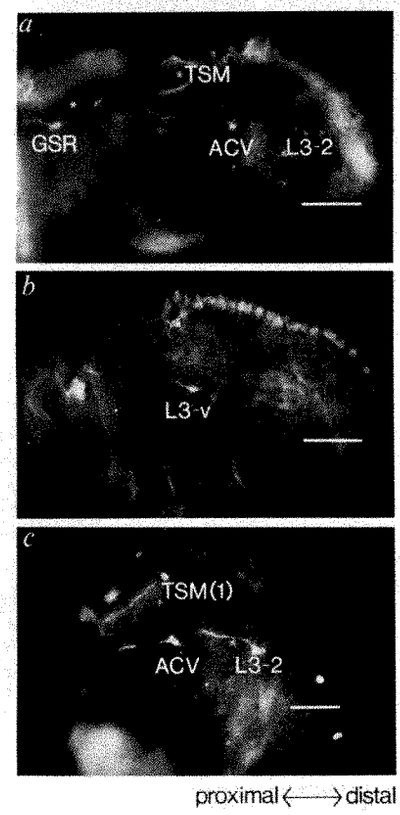

Fig. 3 Cultured wing fragments stained with anti-HRP. *a*, Dorsal wing fragment raised *in vitro* for 22 h. The nerve bundles of the first and third veins have formed normally and join at approximately their normal site just distal to the GSR neurone (compare with Fig. 1), although in this case they failed to grow to the GSR neurone (asterisk marks gap; see text). *b*, Ventral wing fragment, raised *in vitro* for 22 h. The L3-v neurone has formed a short bipolar projection along the proximo-distal axis of the wing; the proximal process is longer than the distal. *c*, Dorso-distal fragment, raised *in vitro* for 8 h. Although the fragment lacked both the GSR neurone and closed channels, the remaining ACV, L3-2 and TSM(1) neurones grew along the correct paths and directions (compare with Fig. 1). Fragments were fixed and stained as described previously[14]. Distal is to the right. Scale bars, 50 μm.

The earliest-developing neurones of the distal wing blade (ACV, TSM(1) and L3-2; see Fig. 1 legend) are all found on the dorsal surface. In dorsal fragments examined after 8 h in culture, the axons of these early neurones had grown in the correct direction along the normal paths (Table 1), either proximally (ACV and L3-2) or proximoposteriorly (TSM(1)). In fragments raised for 22 h, these neurones, together with the later-arising L3-1, L3-3 and Br neurones, formed largely normal nerve bundles (49 of 50 cases; Fig. 3*a*). The only commonly observed abnormality was that the ACV and TSM(1) axons failed to reach the GSR neurone (33 of 49 cases), even though they contacted each other at the usual, slightly more distal, point. This is also common in whole wings raised *in vitro*[14] (under current conditions, 19 of 33 cases) and probably results from damage to the wings or suboptimal culture conditions. In any case, initial outgrowth and most other elements of nerve formation were normal in dorsal fragments despite the lack of channels.

In contrast, axonal outgrowth of the only ventral neurone of the distal wing blade was both delayed and variable in the absence of the dorsal surface. In whole wings, this neurone, the L3-v, initiates axonogenesis only after the early dorsal axons have grown past it (~5 h after pupariation); its process then joins with and apparently follows the early axons. Although this fasciculation obscures the details of further L3-v outgrowth, dye fills in adults demonstrate that the L3-v forms a single, proximally directed axon[16]. In ventral fragments reared for 8 h,

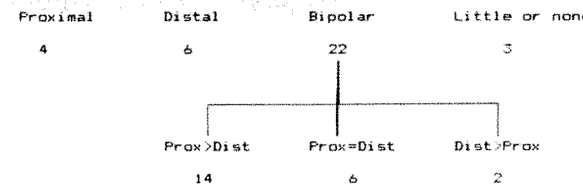

Fig. 4 Direction of outgrowth of the axon of the L3-v neurone in ventral fragments, generated at 2 h after pupariation and cultured for an additional 22 h. Significant outgrowth was taken as outgrowth longer than one neuronal cell diameter. Some branching of axons was observed, but in all cases outgrowth was oriented roughly along the proximo-distal axis of the wing. In five cases a region of dorsal epithelium lay along the anterior of the ventral fragment near the L3-v; in these wings (not included) the L3-v axon grew anteriorly into this region and sometimes seemed to contact the short nerve formed by the TSM neurones. Obviously infected cultures were not included in the data pool.

the L3-v formed no or only very short processes (<1 cell diameter, 20 of 20 cases). By 22 h it usually formed a short bipolar projection (Figs 3*b*, 4); in a few cases, exclusively proximal or distal outgrowth was seen. Because the normal growth pattern of this neurone is not known in detail, it is not certain that these results represent abnormal axonogenesis. However, the variable and generally stunted outgrowth seen in ventral fragments suggest that L3-v axonogenesis was to some extent disrupted by the removal of the dorsal epithelium. Nevertheless, important features of L3-v axonogenesis were retained in ventral fragments: outgrowth was still oriented approximately along the proximo-distal axis of the wing, and was usually, though not always, longer in the proximal than in the distal direction (Fig. 4). Thus, correctly directed axon outgrowth can occur even in a fragment in which the neuronal population is reduced to the greatest possible extent, namely a single cell differentiating in an expanse of epithelium.

Thus, it is apparent that both dorsal and ventral fragments must contain some types of guidance cues other than channels. For example, the filopodia of a neurone might seek out a more proximal 'guidepost' or 'landmark' neurone, which would act as a target for axon growth[17–19]. Guidepost neurones have been shown to have no necessary role in normal *Drosophila* wings[14,20] but might effectively guide neurones in dorsal fragments lacking channels. This possibility was tested by generating fragments, at or before the time of initial axon outgrowth (1.5–2 h after pupariation), from which both proximal tissue (containing a putative guidepost neurone) and the ventral epithelium had been removed. When such dorso-distal fragments were cultured for 8 h, the ACV and TSM(1) neurones still navigated along their normal paths and in their normal directions, even though they lacked both channels and the proximal putative guidepost neurone (GSR) towards which they normally grow (Fig. 3*c*, Table 1). Thus, the GSR neurone does not act as a necessary guidepost for these dorsal neurones, even in the simultaneous absence of obvious physical cues.

Table 1 Fraction of neurones showing normal axonal outgrowth in dorsal and dorso-distal wing fragments

Fragment	ACV	L3-2	TSM(1)
Dorsal	17/17	13/14	14/14
Dorso-distal	11/11	8/8	8/8

Fragments were cut at 2 h after pupariation and cultured for an additional 8 h. Not all neurones could be observed in each fragment. Dorso-distal fragments all lacked the GSR neurone. The single instance of abnormal L3-2 outgrowth consisted of a lengthening of its normally short distal process; this abnormality has also been observed in whole wings raised *in vitro*. Obviously infected cultures were not included in the data pool.

Although there is strong evidence that guidepost neurones can direct growing axons in specific instances in developing insects[18,21,22], even in these cases initial axon outgrowth seems to be directed, as here, by some other cue(s)[18,21]. A one-dimensional gradient of neural adhesivity may provide one such cue[23,24]. However, some features of the axonal pattern in fly wings, such as the angled outgrowth of the TSM(1) axon, are not easily explained by a single gradient, and might require the reading of information in two dimensions. An alternative mechanism that would require less from the neurone would be to possess adhesive cues localized selectively along the normal nerve pathways of the wing[16]. Finally, polarity information intrinsic to each neurone[5] might also guide outgrowth, particularly during its initial stages; extrinsic cues might then be needed only to induce large changes in the trajectory of the growing axon. As the surface along which the neurones of the fly wing navigate can now be exposed without disrupting outgrowth significantly, it may be possible to manipulate this surface directly, to study a variety of putative guidance mechanisms.

Position-dependent properties of retinal axons and their growth cones

Friedrich Bonhoeffer & Julita Huf

Max-Planck-Institut für Entwicklungsbiologie, Spemannstr. 35, D-7400 Tübingen, FRG

The formation of the very orderly neuronal projection from the retina to the optic tectum is not yet understood, but several mechanisms are thought to be involved in a coordinated fashion. These mechanisms may include mechanical or chemical guidance in channels, guidance by spatial gradients of positional markers, gradients of temporal (maturation) markers or specific inter-axon interactions (see ref. 1 for review). The last-mentioned mechanism could explain the fibre order found in optic nerve and tract. It requires that some or all growing retinal axons can distinguish between retinal axons of various origins and grow preferentially along retinal axons originating from the same area as themselves. The *in vitro* experiments described here show that growth cones from the temporal half of the chick retina grow preferentially along temporal axons, whereas growth cones from nasal retina do not distinguish between nasal and temporal axons.

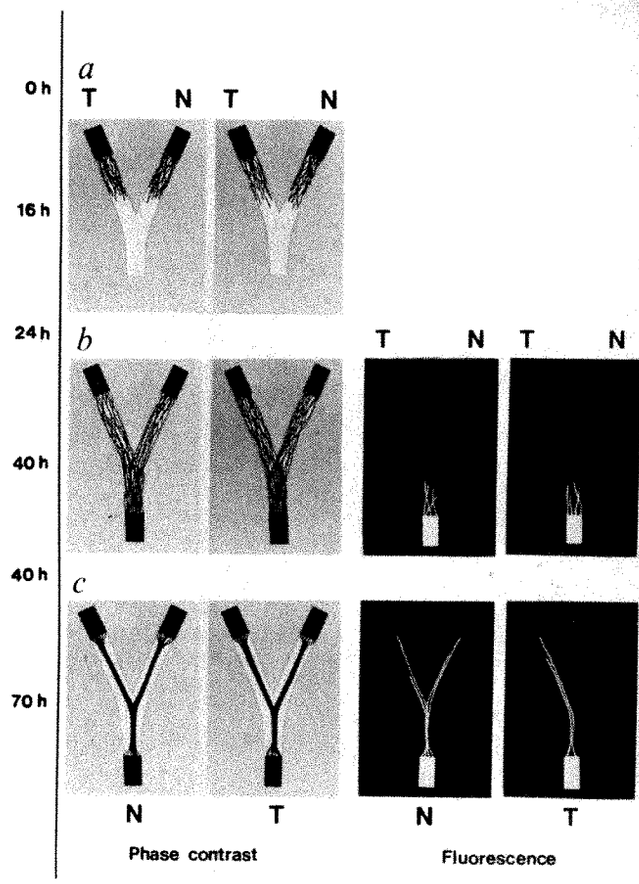

Fig. 1 Schematic description of the experiment. *a*, Phase-contrast diagram of axon growth, with first explantations at 0 h; *b*, explantation of fluorescent explants at 24 h; *c*, addition of α-laminin at 40 h. Axons visualized at 16, 40 and 70 h. T, temporal; N, nasal. **Methods.** Nasal and temporal explants (0.2 × 2 mm) of chick retina were prepared as described previously[6]. They were placed at time 0 onto laminin-coated round coverslips and incubated in culture medium at 37 °C. Laminin was applied to the coverslips by first treating them with 3-(triethoxysilyl)propylamine and then incubating them in laminin (40 $\mu g\ ml^{-1}$) for 3 h at 37 °C. The laminin serves as substrate for growing axons which are visible in phase contrast (*a*). To restrict axonal growth to the indicated Y-shaped field, border lines were drawn with a hypodermic needle on the laminin surface. Axons from nasal and temporal explants joined at the stem of the Y after ~20 h. At ~24 h, a fluorescent explant (either temporal or nasal) was placed at the foot of the Y which was reached by the axons a few hours later. At 40 h the Y-shaped field was crowded with axons as seen in phase contrast and a few fluorescent axons growing up the stem of the Y could be seen in fluorescence (*b*). At about that time, anti-laminin (provided by Dr R. Timpl) was added to the culture. After ~1 h, all fibres were detached from the laminin-coated coverslip and the axons spanned Y-shaped bundles joining the explants. Now the further growth of fluorescent axons (which can be inhibited by antibodies against the cell adhesion molecule N-CAM; ref. 7) could only occur along pre-existing axons. As seen in *c*, temporal fluorescent axons strongly prefer to grow along temporal axons, whereas nasal axons grow along both nasal and temporal axons.

Two 6-day-old chick embryo retinal explants were placed on a laminin-coated coverslip as described in Fig. 1 legend. One explant was taken from the temporal side of the area next to the optic fissure, whereas the other was taken from the nasal side. The axons were forced to grow within predetermined tracks scratched into the laminin so that the axons of both explants met and joined to form a 'Y'-like configuration. (The growth rate of nasal and temporal axons was about the same.) About 24 h later, a third rhodamine-stained fluorescent explant of either nasal or temporal origin was placed near the growth cones at the base of the Y. After a further 16 h, when most of the nasal and temporal axons had reached the labelled explant and some of the fluorescent axons were already leaving it, all axons were

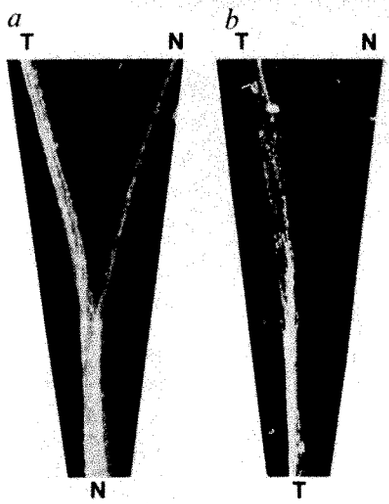

Fig. 2 *a*, Nasal fluorescent axons growing along both the nasal and the temporal axon bundles. The fraction of fluorescent fibres on either bundle is roughly proportional to the thickness of these bundles. *b*, Temporal fluorescent axons growing exclusively along the temporal axon bundle. The nasal axon bundle has been made barely visible by weak dark-field illumination. T, temporal; N, nasal.

detached from the laminin substrate by the addition of anti-laminin.

Because axons are very elastic, they form a structure similar to a tightrope once they lose their contact with the substrate. The only substrate remaining to support further growth of the fluorescent axons was the bundle of axons coming from the two unstained explants; axons had the choice of growing along nasal or temporal fibres within this bundle. Therefore, the preference of the labelled axons became apparent where the bundle bifurcated.

As shown in Figs 1 and 2, all temporal fibres grow towards the temporal explant, that is, they grow preferentially along temporal axons. The results are the same whether the temporal explants stem from more central or more peripheral positions in the retina. On the other hand, nasal fibres show no preference and grow towards either explant. The fraction of nasal fibres growing towards either of the explants is approximately proportional to the relative thickness of the fibre bundle coming from the explant. In Fig. 2*a*, for example, the number of axons growing towards the temporal explant is relatively high because the bundle of temporal fibres was relatively strong.

Of 61 experiments of this type, 53 could be evaluated; in the other 8 cases too few (or no) fibres passed the bifurcation point. The stained explants of the successful experiments were of nasal origin in 34 cases and of temporal origin in 19. Temporal axons grew exclusively towards the temporal explant, whereas nasal axons always grew towards both explants. The fraction of fluorescent axons growing along either unstained bundle was roughly proportional to the relative thickness of these bundles.

According to our results, axons of temporal origin exhibit position-specific properties of self recognition; temporal growth cones recognize temporal axons. From previous observations it is known that temporal axons show a strong tendency to fasciculate with each other (in contrast to nasal axons[2,3]), in good agreement with the observations reported here. Until now, however, it has not been clear whether this difference in behaviour results from different properties of the nasal and temporal growth cones, or their axons, or both. Our experiments indicate that both axons and growth cones of temporal retinal ganglion cells are different from nasal axons and growth cones.

We have also performed analogous experiments concerning the dorso-ventral axis. Explants were taken from dorsal and ventral positions relatively far apart (half the meridian) from both temporal and nasal retina. These experiments have not revealed any position-specific effects. Anatomical investigations have shown that chick retinal axons are already sorted out in the dorso-ventral dimension when they arrive at the tectum, whereas no sorting of nasal and temporal fibres has been detected[4]. Therefore, differences between dorsal and ventral axons in our *in vitro* assay might have been expected rather than differences between nasal and temporal axons, but the opposite is in fact the case. Our finding that temporal axons have a strong preference for growing along other temporal axons *in vitro*, however, is in excellent agreement with *in vivo* observations in the frog[5]. In contrast to the nasal fibres, the temporal axons of frog fasciculate with each other in the optic tract and form a dense bundle. Whether and how these position-specific properties of axons and growth cones are used during the formation of the chick retino-tectal projection is not known.

We thank Drs Alfred Gierer and Jonathan Raper for stimulating discussions and helpful comments on the manuscript.

Synapsin I is a spectrin-binding protein immunologically related to erythrocyte protein 4.1

Anthony J. Baines & Vann Bennett

Department of Cell Biology and Anatomy, Johns Hopkins University School of Medicine, Baltimore, Maryland 21205, USA

The membrane-associated cytoskeleton is considered to be the apparatus by which cells regulate the properties of their plasma membranes, although recent evidence has indicated additional roles for the proteins of this structure, including an involvement in intracellular transport and exocytosis (see refs 1–3 for review). Of the membrane skeletal proteins, to date only spectrin (fodrin) and ankyrin have been purified and characterized from non-erythroid sources. Protein 4.1 in the red cell is a spectrin-binding protein[4,5] that enhances the binding of spectrin to actin[4,6,7] and can apparently bind to at least one transmembrane protein[8–10] Immunoreactive forms of 4.1 have been detected in several cell types, including brain[11–14]. Here we report the purification of brain 4.1 on the basis of its cross-reactivity with erythrocyte 4.1 and spectrin-binding activity. We further show that brain 4.1 is identical to the synaptic vesicle protein, synapsin I, one of the brain's major substrates for cyclic AMP and Ca^{2+}–calmodulin-dependent kinases[15,16]. Spectrin and synapsin are present in brain homogenates in an ~1:1 molar ratio. Although synapsin I has been implicated in synaptic transmission, no activity has been previously ascribed to it.

Antibodies raised against pig erythrocyte 4.1 recognize only protein 4.1 in pig erythrocyte ghosts (Fig. 1). Cross-reactive polypeptides in brain (rat, pig or calf) have an apparent relative molecular mass (M_r) of 75,000 and 73,000 (judged by SDS-gel electrophoresis with a discontinuous buffer system[17]).

The cross-reactive polypeptides were extracted from myelin-depleted brain membranes under conditions similar to those used for the extraction of erythrocyte protein 4.1. Thus, they were virtually inextractable in solutions of low ionic strength but were liberated readily from the membranes by treatment with solutions of higher ionic strength (for example >0.2 M KCl). The extracted protein failed to bind DEAE-cellulose (in 10 mM Na-phosphate at *p*Hs as high as 8.2) or hydroxylapatite in the presence of 1 M KCl. However, it was

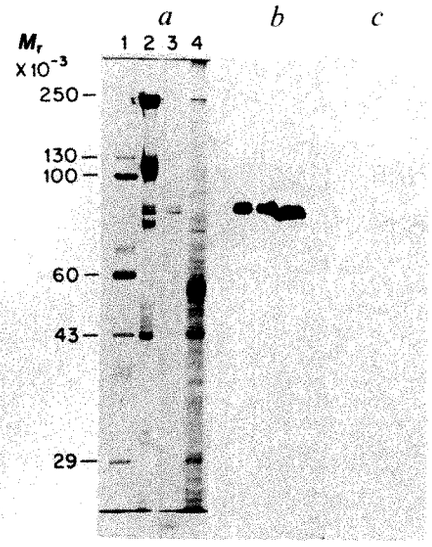

Fig. 1 Identification of a brain protein immunologically related to erythrocyte 4.1. Antibodies were raised in rabbits against SDS-denatured protein 4.1 that had been purified by standard procedures[4,5] and were affinity-purified on 4.1 immobilized on nitrocellulose strips after SDS-gel electrophoresis and blotting[38]. In *a*, *b* and *c*, proteins were electrophoresed on 9% SDS-polyacrylamide gels[17] and stained with Coomassie blue (*a*) or transferred to nitrocellulose paper[27] (*b*, *c*) for reaction with anti-red blood cell (RBC) 4.1 antibodies and ^{125}I-protein A (*b*) or non-immune IgG (*c*). Lanes 1, M_r standards: filamin (250,000), vinculin (130,000), α-actinin (100,000), catalase (60,000), actin (43,000), cabonic anhydrase (29,000); lanes 2, pig RBC ghosts; 3, pig RBC 4.1; 4, pig brain post-nuclear supernatant.

retained by carboxymethyl-cellulose and by hydroxylapatite at low ionic strength and *p*H 6.8. These properties are those of a very basic protein[18] and allowed the scheme for purification shown in Fig. 2. The purified brain 4.1 displayed anomalous migration between different SDS gel systems. Using a continuous gel buffer[19] we obtained subunits of M_r 88,000 and 85,000: in this system, brain 4.1 migrates more slowly than erythrocyte 4.1, as has been observed previously[12].

The spectrin-binding activity of brain 4.1 was shown using 'blot binding' techniques in which fractions were taken from various stages of purification of brain 4.1 and were electrophoretically separated, transferred to nitrocellulose and incubated with ^{125}I-labelled erythrocyte spectrin (Fig. 2). As a control for nonspecific binding, additional unlabelled spectrin was included in some of the incubations to displace specific binding. Brain 4.1 at later stages of the purification specifically binds ^{125}I-spectrin on the nitrocellulose (Fig. 2*a*,*b*), but this method was not sensitive enough to detect brain 4.1 in early stages of the purification. Other basic proteins (notably myelin basic protein) do not bind ^{125}I-spectrin.

Conversely, ^{125}I-brain 4.1 was incubated with blots on which erythrocyte and brain spectrins were immobilized (Fig. 3). As controls for nonspecific binding, we used heat-denatured ^{125}I-brain 4.1. As additional internal controls for binding of a basic protein (brain 4.1) to an acidic protein (spectrin), actin, tropomyosin and total erythrocyte ghost proteins were included in the blots. Again, we find specific binding of the ^{125}I-brain 4.1 to spectrin. One characteristic of erythrocyte 4.1 is that it binds to both α- and β-subunits of erythrocyte spectrin[7]. Blots in which ^{125}I-brain 4.1 was incubated with isolated α- and β-subunits of brain spectrin showed specific binding to both. Preliminary results indicate that brain 4.1 and erythrocyte 4.1 compete for the same site on brain spectrin, as brain 4.1 displaces binding of ^{125}I-brain spectrin to erythrocyte 4.1 on blots (not shown). The interaction between brain 4.1 and brain spectrin is also demonstrable by affinity chromatography (not shown).

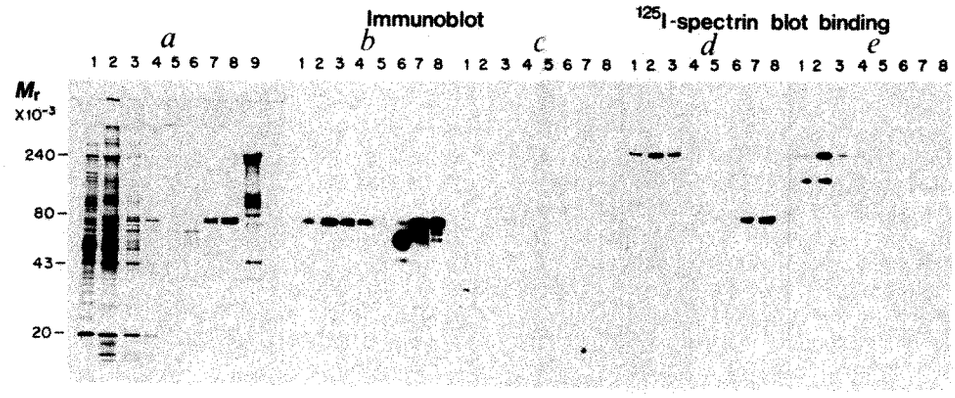

Fig. 2 Purification of brain 4.1. Fractions from the purification procedure were analysed on 5–15% polyacrylamide gels, which were stained with Coomassie blue (*a*) or transferred to nitrocellulose[27] (*b*–*e*). Nitrocellulose replicas were reacted with: *b*, anti-RBC 4.1; or *c*, non-immune IgG followed by ^{125}I-protein A. In *d* and *e* they were incubated with ^{125}I-RBC spectrin (20 nM, 2×10^6 c.p.m. ml^{-1} as described in ref. 27) in the absence (*d*) or presence (*e*) of a 20 fold excess of unlabelled spectrin. Lanes 1, myelin-depleted pig brain membranes; 2, 0.25 M KCl extract; 3, first hydroxylapatite (HA) column eluate; 4, DEAE supernatant; 5, carboxymethyl-cellulose (CMC) flow-through; 6, 30 mM NaCl eluate; 7, 60 mM NaCl eluate from CMC; 8, second HA column, $MgCl_2$ eluate; 9, M_r standards (human erythrocyte ghosts). In *b*, lane 8 contains half the amount of protein loaded in the corresponding lanes in *a* and *c*–*e*.

Methods. Myelin-depleted membranes[27] from pig brain (350–450 g) were washed twice with 40 mM KCl, 2 mM EGTA in buffer A (10 mM Na-phosphate, 1 mM dithiothreitol (DTT), 1 mM NaN_3, 1 μg ml^{-1} leupeptin, 1 μg ml^{-1} pepstatin A, 1 μg ml^{-1} chymostatin, 200 μg ml^{-1} phenylmethylsylphonyl fluoride (PMSF), 1 mM diisopropyl fluorophosphate (DFP) *p*H 7.4) and were brought to 1:1 with buffer A containing 0.25 M KCl and 2 mM EGTA. Incubation at 37 °C for 30 min released most of the cross-reactive peptides, which were recovered in the supernatant after centrifugation at 30,000*g* for 30 min. The protein extract was concentrated 10-fold by precipitation with ammonium sulphate at 65% saturation and resuspended in, and dialysed against, 1 M KCl, 1 mM EDTA, 0.1% Tween 20 in buffer A lacking DFP. After centrifugation at 180,000*g* for 90 min, the supernatant was made 5 mM in $MgCl_2$ and applied to a 20-ml column of hydroxylapatite (fast flow, Calbiochem) equilibrated with 1 M KCl, 10 mM Na-phosphate, 5 mM $MgCl_2$, *p*H 7.4. The void volume, containing the cross-reactive peptides, was dialysed extensively against 1 mM EDTA in buffer A lacking DFP, followed by batchwise absorption with 10 ml DEAE-cellulose (Whatman DE53, equilibrated with buffer A, lacking DFP): cross-reactive peptides were recovered in the supernatant after centrifugation at 1,000*g* for 2 min. The supernatant was applied to a 10-ml column of carboxymethyl-cellulose (Whatman CM32), equilibrated with buffer B (10 mM Na-phosphate, 1 mM EDTA, 0.1% Tween 20, 0.5 mM DTT, 1 mM NaN_3, *p*H 7.4), then the column was washed with buffer B and eluted stepwise with 30 mM NaCl in buffer B and 60 mM NaCl, 5 μg ml^{-1} leupeptin in buffer B. Peak fractions from the second step were dialysed against buffer C (1 mM Na-PIPES, 0.1 mM DTT, 0.05% Tween 20, 1 mM NaN_3, 1 μg ml^{-1} leupeptin *p*H 6.8) and applied to a 2-ml column of hydroxylapatite (high-resolution (Calbiochem), equilibrated with buffer C). Cross-reactive spectrin-binding peptides were eluted with 5 mM $MgCl_2$ in buffer C. Yields of 2–5 mg were typically obtained. The protein was typically 90–95% pure when prepared from pig brain, but a contaminant of M_r 48,000 was present as 10–15% of the total protein when this method was applied to calf brain. This yield represents ≥2% of the total brain 4.1 in a homogenate, major losses occurring because of incomplete extraction from membranes, proteolysis and adsorption to surfaces.

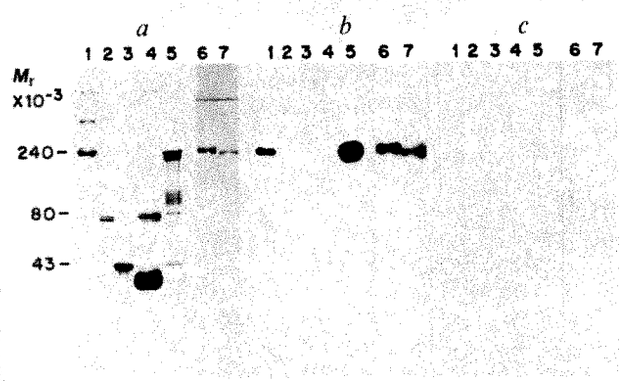

Fig. 3 ^{125}I-brain 4.1 specifically binds to erythrocyte and brain spectrin, α- and β-subunits. After SDS-gel electrophoresis on 5–15% gels, proteins were either stained with Coomassie blue (*a*) or electrophoretically transferred to nitrocellulose (*b*, *c*). Lanes 1, pig brain spectrin; 2, pig brain 4.1; 3, rabbit skeletal muscle actin; 4, rabbit skeletal muscle tropomyosin; 5, human erythrocyte ghosts; 6, brain spectrin α-subunit; 7, brain spectrin β-subunit. Actin, tropomyosin and ghost proteins were included as additional controls for nonspecific interaction between acidic proteins and a basic protein (brain 4.1). Brain spectrin and its subunits were prepared as described previously[27]. Nitrocellulose replicas were incubated with ^{125}I-brain 4.2 (10 nM, 2×10^6 c.p.m. ml^{-1}) in blot buffer (4% (w/v) bovine serum albumin (Pentex), 0.15 M NaCl, 10 mM Na-phosphate, 1 mM EDTA, 0.2% Triton X-100, 1 mM NaN_3, *p*H 7.1) for 18 h at 4 °C. In *c*, the ^{125}I-brain 4.1 had been denatured by heating to 60 °C for 20 min before incubation with the nitrocellulose paper. Unbound ^{125}I-brain 4.1 was removed by washing the replicas five times with blot buffer lacking albumin.

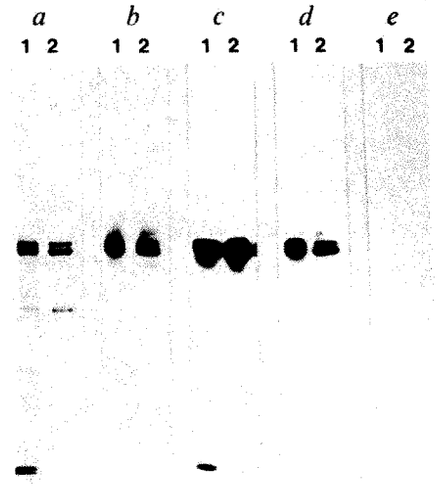

Fig. 4 Synapsin I cross-reacts with anti-RBC 4.1 and anti-brain 4.1 antibodies and binds ^{125}I-spectrin. Samples of bovine synapsin I (lanes 1) and bovine brain 4.1 (lanes 2) were electrophoresed on polyacrylamide gels which were stained with Coomassie blue (*a*) or transferred to nitrocellulose paper (*b*–*e*). The nitrocellulose paper was reacted[27] with: *b*, anti-RBC 4.1 and ^{125}I-protein A; *c*, anti-brain 4.1 and ^{125}I-protein A; *d*, ^{125}I-brain spectrin (20 nM, 2×10^6 c.p.m. ml^{-1}); and *e*, ^{125}I-brain spectrin in the presence of a 40-fold excess of unlabelled spectrin.

Brain and erythrocyte 4.1 are the products of different genes, with distinct two-dimensional peptide maps (not shown). Similarly, mammalian brain spectrin[20,21] and brain ankyrin[22] have fingerprints distinct from their erythrocyte counterparts. However, the two components of brain 4.1 give rise to nearly identical fingerprints (not shown). Limited chymotryptic digests of brain 4.1 resolved on SDS gels show ~10 peptides which cross-react with erythrocyte 4.1, suggesting a substantial degree of antigenic homology (not shown).

Like erythrocyte 4.1 (ref. 23), brain 4.1 is a substrate for cAMP-dependent kinase. When brain membranes were incubated with [γ-^{32}P]ATP and 10 μM cAMP, a pair of polypeptides became labelled which are specifically immunoprecipitable with anti-brain 4.1 antibody. In the absence of cAMP, these polypeptides do not become appreciably labelled (data not shown).

We conclude that the protein we have purified is closely related to erythrocyte 4.1, because: (1) it has cross-reactivity with anti-4.1 IgG; (2) it consists of two basic, sequence-related polypeptides; (3) it binds spectrin; and (4) it is a subtrate for cAMP-dependent protein kinases.

The properties of brain 4.1 are strikingly similar to those of synapsin I, a protein associated with synaptic vesicles[24]. Synapsin I was initially identified as a major substrate in brain for cAMP-dependent protein kinase[15] and is a doublet of M_r ~80,000 on SDS gels[25].

The physical properties of brain 4.1 and synapsin I are similar: synapsin I is basic (*p*I 10.3) with two polypeptide components that give rise to similar peptide maps[25]. Both brain 4.1 and synapsin I[26] are released from brain membranes in solutions of >0.15 M KCl. Immunoprecipitated ^{32}P-brain 4.1 co-migrates on SDS gels with a pair of ^{32}P-polypeptide that seem to be those defined by Johnson *et al.*[15] as synapsin I (not shown).

Standard synapsin I, prepared by extraction of brain membranes of *p*H 3, isoelectric precipitation of contaminants at *p*H 6, followed by hydroxylapatite and gel-filtration chromatography[25] (a gift of Dr H. C. Palfrey) has identical electrophoretic mobility on SDS gels to brain 4.1 (Fig. 4). Synapsin I and brain 4.1 were immunologically cross-reactive, as they both reacted on SDS gel blots with anti-red cell 4.1 and anti-brain 4.1 IgG, but not with non-immune IgG. Furthermore, they both bind ^{125}I-brain spectrin on gel blots, the binding being displaceable with unlabelled spectrin.

Finally, two-dimensional ^{125}I-iodo peptide maps of synapsin I and brain 4.1 are identical in all but two (minor) spots out of some 30 visible on the maps (Fig. 5), the variant spots differing only in their mobilities on the plates. The variations in the two spots need not imply variations in primary structure, but may reflect different post-translational modifications. Differing phosphorylation states, or modification to the proteins that occurred during their preparation, might give rise to such variation. The proteins clearly have very closely related amino-acid sequences and we believe that they are one and the same.

Synapsin I has previously only been studied as a substrate for protein kinases and its function was unknown. Here we report the first evidence that synapsin is a spectrin-binding protein which seems to be related to erythrocyte membrane skeletal protein 4.1.

An estimate of the stoichiometry of spectrin and synapsin I can be made: in whole brain homogenates, spectrin dimer (M_r = 500,000) comprises 2.4% of the total protein[27] and synapsin I (M_r = 75,000) 0.4% (ref. 28). These values correspond to 48 pmol spectrin and 53 pmol synapsin per mg total protein, that is, close to a ratio of 1:1. This stoichiometry is similar to that of the corresponding proteins in the erythrocyte[29].

The subcellular organization of spectrin in neurones has not yet been determined precisely. However, both spectrin and synapsin I are enriched in synapses[24,30] and are prominent components of isolated synaptosomes[26,31]. Spectrin is also a prominent component of the postsynaptic density[32]. Initial work suggested that synapsin I was a component of the postsynaptic density[33], but DeCamilli *et al.*[24] concluded it was not, although they could not eliminate the possibility that their antibody was excluded from the postsynaptic density. Bearing in mind that synapsin is present stoichiometrically with spectrin, this point is open to re-examination. Furthermore, recent work[12,34] suggests that although proteins immunoreactive with erythrocyte spectrin and 4.1 (presumably brain spectrin and synapsin) co-localize in neurones, they occur predominantly in the neuronal perikarya.

A spectrin–synapsin linkage may play a part in neurotransmission. Spectrin may afford a linkage (via synapsin) between

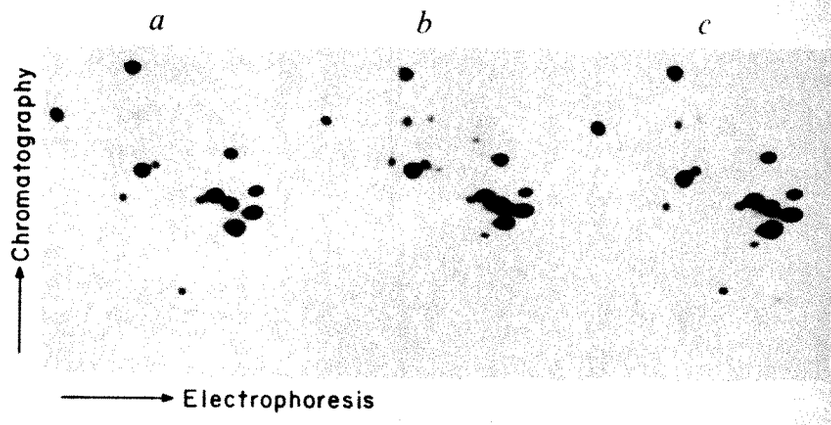

Fig. 5 Brain 4.1 and synapsin I have very similar peptide maps. *a*, Brain 4.1; *b*, synapsin; *c*, a mixture of brain 4.1 and synapsin. Peptide maps of bovine brain 4.1 and bovine synapsin I were prepared by the method described in ref. 27.

synaptic vesicles and the plasma membrane. However, spectrin has also been identified as an axonally transported protein, sometimes associated with membrane-bounded organelles[35]. Thus, an additional or alternative role for spectrin and synapsin might encompass linkage (or regulation of linkage) of synaptic vesicles to cytoskeletal elements. Such cytoskeletal elements need not be only actin. Although erythrocyte 4.1 seems to enhance the binding of brain spectrin to actin[36], our preliminary results have not so far revealed such a role for synapsin. However, synapsin may bind microtubules (unpublished data), which are also present in synaptosomes[31].

Erythrocyte 4.1 is able to bind at least one transmembrane protein. Binding of synapsin to a transmembrane protein of the synaptic vesicle may be of importance in regulation of neurotransmitter secretion, as synapsin is released from its membrane binding site on phosphorylation of synapsin by cAMP- or Ca^{2+}/calmodulin-dependent protein kinases[26], which phosphorylate synapsin in response to hormonal or electrical stimulation of nerves[37].

The neurohumoral regulation of growth hormone secretion is mediated in part by two hypothalamic peptides that reach the anterior pituitary via the hypothalamo-hypophysial portal blood system[1]. Somatostatin inhibits the release of growth hormone[2], whereas growth hormone-releasing factor (GRF) positively regulates both growth hormone synthesis[3,4] and secretion[5,6]. Two forms of human GRF, 40 and 44 amino acids long, have been characterized from extra-hypothalamic tumours[7,8] as well as from the hypothalamus[9]. Analysis of human GRF complementary DNA[10,11] and genomic[12] clones indicates that the GRF peptides are first synthesized as a 107- or 108-amino-acid precursor protein. To examine the physiological consequences of GRF expression, we have established strains of transgenic mice containing a fusion gene including the promoter/regulatory region of the mouse metallothionein-I (MT-I) gene[13] and the coding region of the human GRF gene[12]. We report that expression of the human GRF precursor protein in these animals results in measurable levels of human GRF and increased levels of mouse growth hormone in plasma and accelerated growth rates relative to control littermates. These results demonstrate a direct role for GRF in the positive regulation of somatic growth. Unexpectedly, female transgenic mice carrying the MT-GRF fusion gene are fertile, in contrast to female transgenic mice expressing human or rat growth hormone, which are generally infertile. These transgenic mouse strains should provide useful animal models for the study of several types of human growth disorders.

It was shown previously that the hormonal cascade controlling somatic growth could be manipulated by the germline introduction of foreign genes. Expression of either rat[14] or human[15] growth hormone (GH) in transgenic mice results in increased growth rates, giving rise to large animals. Because GRF is believed to be an important physiological regulator of growth hormone in animals, we sought to analyse further its role in growth control by creating strains of animals that express supraphysiological levels of GRF. Neither rat nor human growth hormone genes are themselves expressed in transgenic animals[16,17]; this deficiency has been overcome by fusing these structural genes to an expressed heterologous gene promoter.

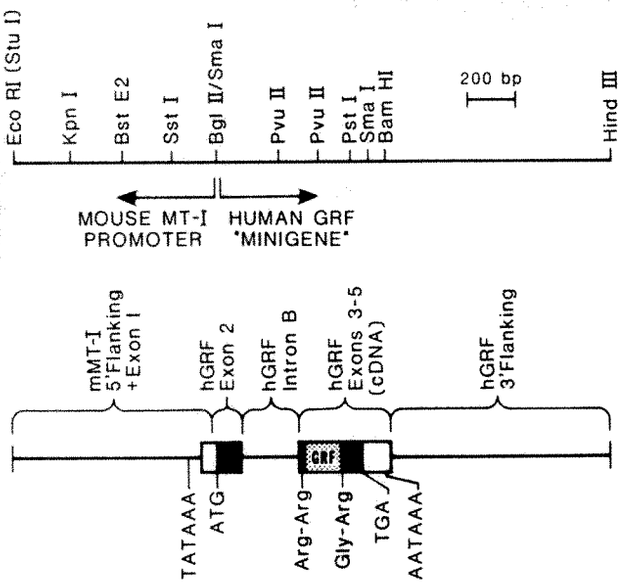

Fig. 1 Structure of the mouse metallothionein-I/human growth hormone-releasing factor fusion gene. The upper portion of the figure is a restriction map for common 6-bp cutters. *Bgl*II/*Sma*I indicates the site of the fusion between the mouse MT-I promoter and the human GRF minigene. The lower portion of the figure is a schematic representation of the 2.5-kb *Eco*RI–*Hin*dIII fragment of DNA used for microinjection. Open boxes represent 5′ and 3′ untranslated exon regions, and shaded boxes represent the coding exon regions. The derivations of various parts of the fusion gene are indicated. The fusion occurs in the 5′ untranslated regions of both genes. The large exon labelled 3–5 was constructed by replacing part of the human GRF gene with a human GRF cDNA, effectively eliminating intron C (2.4 kb) and intron D (3.0 kb) of the human GRF gene[12]. Consensus sequences involved in transcription initiation, translation initiation and termination, polyadenylation, and proteolytic processing of the GRF peptide from its precursor are shown.

The mouse metallothionein-I gene promoter offers several advantages for this type of approach; it is expressed at fairly high levels in most mouse tissues[18], it can be regulated by heavy metals[18], and both expression and regulation are retained in gene transfer experiments[19–21]. Because of the possibility that the human GRF gene, like the human growth hormone gene, might not be expressed in transgenic animals, we initially chose to use the heterologous mouse MT-I promoter to express human GRF.

The structure of the mouse MT-I/human GRF fusion gene construct used (referred to as MT-GRF) is shown in Fig. 1. A 770-base pair (bp) fragment of the mouse MT-I gene, including sequences responsible for metal-inducibility and transcription initiation, was fused to a human GRF minigene which includes the entire coding region of the GRF precursor protein. The human GRF minigene was created by combining cDNA and genomic clones such that the 10-kilobase (kb) human GRF gene, which normally includes five exons[12], has been reduced to <1 kb and retains a single intron of 230 bp (see Fig. 1). Analysis of human GRF cDNA clones suggests that the GRF precursor protein can consist of either 107 or 108 amino acids, differing in the presence or absence of serine 103 (ref. 11). DNA sequence analysis of the human GRF gene[12] indicates that this difference may be explained by alternative RNA processing. The cDNA used to construct the MT-GRF fusion gene should encode only the 108-amino-acid form of the GRF precursor protein[10]. To determine whether the MT-GRF fusion gene could be expressed and regulated correctly, it was introduced into cultured mouse fibroblast cells using $CaPO_4$-mediated DNA transfection[22] and co-selection for neomycin resistance conferred by the vector pSV2-neo[23]. Several stable cell lines that were generated in this manner express a MT-GRF fusion mRNA of the expected size whose abundance is increased by metal treatment, and accumulate radioassayable human GRF (hGRF) in the culture medium (K.E.M., unpublished results).

Table 1 Expression of the MT-GRF fusion gene in transgenic mice

Mouse	No. of gene copies per cell	Liver GRF mRNA (relative amount)	Plasma hGRF (ng ml^{-1})	Plasma mGH (ng ml^{-1})	Growth (ratio)
♂760-5	<1	3	24	1,051	1.35
♂762-3	2	0	<10	21	0.93
♀762-5	4	63	26	141	1.33
♀765-2	2	102	207	415	1.24
♂800-1	1	0	<10	149	1.12
♀800-8	1	3	14	402	1.05
♂801-3	3	0	<10	38	0.97
♀801-5	8	38	99	809	1.35
♂801-9	1	4	20	541	1.42
♀802-3	5	1	45	913	1.51
♀803-4	10	118	263	1,095	1.41
♀803-5	1	5	24	166	1.45
♂803-6	10	16	50	302	1.24
♀803-7	20	*	*	*	1.36

A 2.5-kb *Eco*RI–*Hin*dIII fragment containing the MT-GRF fusion gene was microinjected into the male pronucleus of fertilized F_2 hybrid mouse eggs and the eggs implanted into the oviducts of pseudopregnant recipients[24]. At weaning, DNA was isolated from a piece of tail and analysed for the fusion gene by dot-blotting using a human GRF cDNA as probe[10]. Positive animals were re-analysed by Southern DNA blotting and copy number determined by comparison with a standard curve generated from known amounts of MT-GRF plasmid DNA. Positive animals were maintained on water containing 25 mM $ZnSO_4$. RNA was isolated following partial hepatectomy and analysed by Northern blotting using a human GRF cDNA probe. Autoradiograms were densitometrically scanned to determine relative RNA amounts. Plasma GRF and GH were determined by radioimmunoassay of serum samples from animals at 9 weeks old. The GH radioimmunoassay was able to detect 16 ng ml^{-1} serum GH (two control animals had 16 and 46 ng ml^{-1} GH) and the GRF radioimmunoassay was able to detect 10 ng ml^{-1} serum GRF (two control animals had <10 ng ml^{-1} GRF). The growth ratio was determined at 9 weeks of age and represents a comparison with age- and sex-matched littermates.

* ♀803-7 died prematurely. Although we were able to measure liver GRF mRNA, the amount could not be quantitated because of RNA degradation in the postmortem liver. Plasma GRF and GH levels could not be determined accurately for the same reason.

The MT-GRF fusion gene (~1,600 molecules) was microinjected into the male pronucleus of 350 F_2 hybrid eggs (obtained by mating C57BL/6×SJL hybrid adults) and the eggs were transferred into the oviducts of pseudopregnant recipients as described elsewhere[24]. Fifty-nine animals developed from the microinjected eggs; at the time of weaning, DNA was isolated from a piece of tail taken from these animals. The presence of the foreign MT-GRF gene was detected by hybridization to a human GRF cDNA clone[10] using conditions in which cross-hybridization with the mouse GRF gene is negligible. Fourteen animals carried the MT-GRF fusion gene; these animals were maintained on water with 25 mM $ZnSO_4$ to enhance expression of the fusion gene[15]. Table 1 summarizes the expression of the MT-GRF fusion gene in these 14 transgenic mice; 11 of the 14 animals express the MT-GRF messenger RNA in the liver, a major site of metallothionein expression[18]. The amount of the fusion mRNA in the livers of these mice varies by as much as 100-fold, and does not seem to be strongly correlated with the number of copies of the fusion gene in each animal. Animals expressing the fusion gene have measurable levels of human GRF in their serum, and have increased levels of serum growth hormone (Table 1). Ten of the mice showed significant increases in growth at 9 weeks old, and were 25–50% larger than control littermates. At maturity, some of the MT-GRF animals were nearly twice the size of control animals. Examination of the data in Table 1 reveals that there is no strong correlation between GRF levels, GH levels and growth.

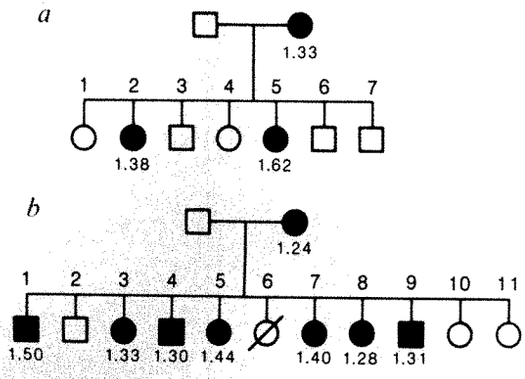

Fig. 2 Pedigree analysis of MT-GRF transgenic mice. Mice that carry the MT-GRF fusion gene (determined by DNA blotting of tail snips) are indicated by the solid symbols. Squares represent males and circles represent females. The animal number is given above each symbol; the numbers below the solid symbols indicate weight ratios at 9 weeks old compared with age- and sex-matched littermates. *a*, Pedigree of MT-GRF mouse ♀762-5; *b*, that of MT-GRF mouse ♀765-2. Mouse ♀765-2-6 died but was previously scored as a non-carrier.

To determine whether the MT-GRF fusion gene and the large size are heritable, two of the MT-GRF founder animals were bred with control animals; offspring from these matings were analysed for the presence of the MT-GRF fusion gene and for their rate of growth. Figure 2 shows two pedigrees demonstrating that both the fusion gene and the 'large' phenotype are inherited by ~50% of the total offspring. DNA analysis showed that all positive offspring carried the same number of copies of the fusion gene as the corresponding parent (data not shown). Four other females were also mated and produced litters. Thus, all six of the females tested were fertile (two were killed before breeding). In addition, male MT-GRF mice 760-5 and 801-9 (see Table 1) sired litters that included offspring carrying the fusion gene and displaying the large phenotype, indicating that both males and females carrying the MT-GRF fusion gene are fertile and transmit the gene. We now know that both the MT-GRF fusion gene and the large phenotype are inherited by ~50% of the offspring examined in the F_2 generation of animals.

To determine whether expression of the MT-GRF fusion gene in transgenic mice demonstrates a tissue specificity similar to that of the endogenous MT-I gene, we analysed both MT-I and MT-GRF RNAs in six tissues from either a control mouse or an MT-GRF mouse (female 765-2-3) (see F_1 in Fig. 2*b*); the results are presented in Fig. 3. The control animal expressed MT-I mRNA at high levels in liver, kidney, gut and pancreas, and at lower levels in brain and spleen. This agrees well with the known tissue distribution of MT-I mRNA[18]. The control animal did not express detectable hGRF mRNA in any tissue. Although the hGRF probe might detect endogenous mouse GRF mRNA in the brain, the low abundance of GRF mRNA even in the hypothalamus (<0.01%) makes detection unlikely. The transgenic mouse ♀765-2-3 showed a tissue distribution of MT-I mRNA much like that of the control mouse with one exception; the amount of liver MT-I mRNA was substantially reduced (Fig. 3). The reason for this is unclear, but it cannot be explained by RNA degradation and is a reproducible result in this animal. In the transgenic mouse, the MT-GRF fusion mRNA is expressed at high levels in the liver, gut and pancreas, at low levels in kidney and spleen, and was not detected in the brain (Fig. 3). Although the expression of the fusion gene in this animal demonstrates a tissue specificity similar to that of the mouse MT-I gene, there are clear and reproducible differences, most noticeably the low level of expression of MT-GRF mRNA in the kidney. We have recently examined the pattern of MT-GRF gene expression in a second pedigree (♂801-5-9) and have found that although the general pattern of tissue specificity parallels that of mouse MT-I, there are subtle differences particular to this animal and distinct from the MT-GRF animal ♀765-2-3 (data not shown). Similar results were obtained on examination of the tissue specificity of metallothionein/growth hormone fusion genes[15]. In this case, an extensive survey of multiple animals showed that expression varied among different tissues and different animals, suggesting that factors such as the site of integration probably influence expression of the foreign gene.

Although many tissues apparently express the MT-GRF mRNA and presumably synthesize the GRF precursor protein, we do not know which tissues are capable of proteolytically processing this precursor to generate the mature GRF peptide. The antibody used to detect plasma GRF would detect both the precursor and the mature peptide[10]. It seems likely that such processing must occur to some extent, as the free N-terminus of the GRF peptide is known to be required for biological activity[7,8]. We are presently using chromatographic techniques to determine what percentage of the immunoassayable GRF in the plasma is mature peptide as opposed to precursor.

Our results demonstrate that expression of supraphysiological levels of GRF in mice leads to increased somatic growth. Conversely, it has been shown that passive immunization of rats with antibodies against GRF can inhibit somatic growth[25]. Taken

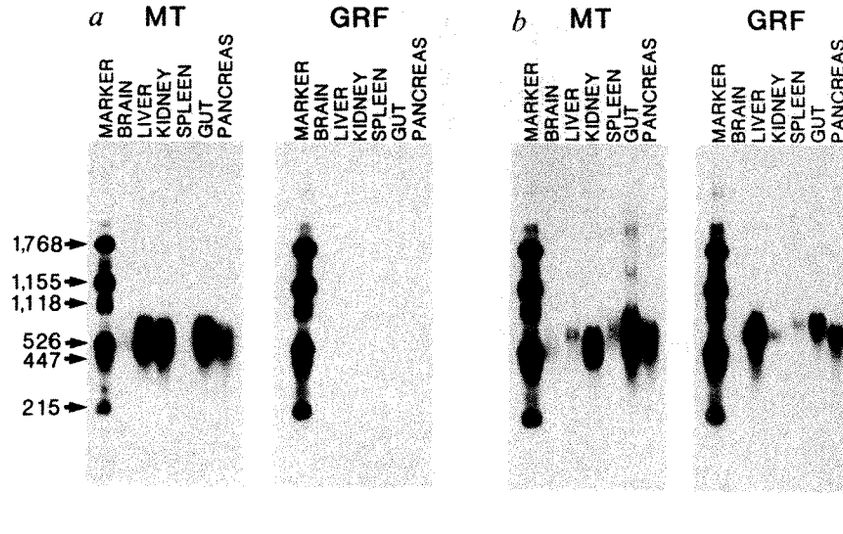

Fig. 3 Expression of human GRF mRNA in MT-GRF transgenic mice. *a*, Results from a control mouse; *b*, results from MT-GRF transgenic mouse ♀765-2-3. Each panel shows Northern blots of RNAs isolated from six different tissues. Duplicate blots from each animal were probed with either mouse MT-I (mMT-I) or hGRF probes as indicated. Size markers (in nucleotides) are denatured *Hin*dIII-cut simian virus 40 DNA.

Methods. Both animals were maintained on water with 76 mM $ZnSO_4$ for several weeks before killing. The indicated organs were removed and frozen at −70 °C until use. Total RNA was prepared by homogenization in guanidine isothiocyanate and centrifugation through caesium chloride as described[29]; 5 μg of each RNA was denatured and electrophoresed on formaldehyde/1.5% agarose gels[30] and the RNA transferred to nitrocellulose filters as described[31]. Filters were probed with either a mouse MT-I genomic clone, pSH[13], or a human GRF cDNA clone, phGRF-54 (ref. 10). Probes were labelled by nick-translation using [α-^{32}P]dCTP (NEN). Exposure time of the autoradiograms ~16 h.

together, these data suggest strongly that GRF has an important role in the promotion of growth. Transgenic mice carrying the MT-GRF fusion gene have elevated levels of plasma growth hormone and grow at a rate 25–50% greater than that of control littermates; this is significantly less than the increased growth observed in transgenic mice expressing growth hormone, many of which grow to twice the normal size[14,15]. However, in the transgenic animals expressing growth hormone, most body tissues express the gene and have the potential to make growth hormone, whereas in our experiments growth hormone is only made in the anterior pituitary and thus may be rate-limiting. An unexpected finding was that females expressing the MT-GRF fusion gene are fertile, although transgenic female mice expressing the growth hormone gene are generally infertile[16]; this suggests that the enhancement of growth in the MT-GRF females is more physiological, perhaps because the effect is mediated through endogenous somatotropes.

We examined the pituitaries of two MT-GRF transgenic animals that express the fusion gene at high levels (♀762-5 and ♀765-2-3). In both cases the pituitary was at least three times normal size and showed signs of marked hyperplasia. The condition of these animals is remarkably similar to the clinical findings in patients with certain types of human growth disorders characterized by elevated levels of growth hormone in serum and pituitary hyperplasia. Rather than pituitary adenoma, the more common cause of such symptoms, a tumour is found at a remote site, often a pancreatic or bronchial carcinoma[26–28]. These tumours do not produce growth hormone, yet on resection plasma GH levels fall. Such rare tumours are now recognized to be ectopic sources of GRF[7,8] and the MT-GRF transgenic mice seem to provide a good animal model for this class of growth disorders. The finding of pituitary hyperplasia suggests that GRF, in addition to regulating GH production, might have a role in somatotroph proliferation.

We thank Richard Palmiter for providing the mouse MT-I promoter and for continued interest in the project, Gail Cerelli, Paul Fallon and Myrna Trumbauer for technical assistance, the laboratory of Wylie Vale for GRF and GH radioimmunoassays, and Marijke terHorst for preparing the manuscript. This work was supported by grants from the NIH and NIAMDD to R.M.E., and from the NIH to R.L.B. R.E.H. was supported by NIH training grant HD07155 and K.E.M. by Damon Runyon-Walter Winchell Cancer Fund Fellowship DRG-648.

Phagosome acidification blocked by intracellular *Toxoplasma gondii*

L. David Sibley*, Earl Weidner* & James L. Krahenbuhl†

* Department of Zoology and Physiology, Louisiana State University, Baton Rouge, Louisiana 70803, USA
† Department of Immunology Research, National Hansen's Disease Center, Carville, Louisiana 70721, USA

***Toxoplasma gondii* belongs to a group of highly virulent intracellular parasites that reside in host cell vacuoles which resist typical phagosome–lysosome fusion[1]. Live *Toxoplasma* replicate prodigiously within modified phagocytic vacuoles formed during invagination of the host plasma membrane[2,3]. In contrast, heat-killed *Toxoplasma* or specific antibody (heat-inactivated)-coated live *Toxoplasma*-containing vacuoles readily undergo lysosome fusion and digestion in normal macrophages[2,4]. Of newly recognized significance to *Toxoplasma* survival is the microbicidal effect of phagosome acidification, which reportedly can occur independently of fusion with other acidic vesicles[5–8]. We report here that modified live *Toxoplasma*-containing vacuoles fail to acidify in normal macrophages, as indicated by the sensitive *p*H probe fluorescein. In contrast, when live *Toxoplasma* are coated with specific antibody (heat-inactivated), they trigger phagosome acidification when entering normal macrophages. A similar acidification is observed when normal phagocytes ingest dead *Toxoplasma*. Extracellular *Toxoplasma* are highly susceptible to acidic *p*H conditions, indicating that the acidification block in the modified vacuoles may be important for intracellular survival.**

The endogenous acidification of macrophage phagosomes may involve two independent mechanisms that operate before acidic vesicle fusion. First, NADPH-oxidase activity, associated with the phagocytic respiratory burst, forms superoxide radicals and delivers H^+ ions to the phagosome[5]. Second, phagosome acidification may involve the Mg-ATPase H^+-ion pump identified in pinosomes[9] and ligand-receptor endosomes[10–15] also formed by plasma membrane invagination. Given the potential for similar acidic changes in newly formed phagosomes[6] and the *p*H susceptibility of *Toxoplasma*[16,17], we investigated how the *in situ p*H of macrophage vacuoles containing *Toxoplasma* affected intracellular survival.

The fate of live compared with heat-killed or antibody-coated *Toxoplasma* in normal or activated mouse peritoneal macrophages was evaluated microscopically at intervals after infection *in vitro*. Live *Toxoplasma* here refers to extracellular parasites freshly collected from mouse ascites[18], representing the maximum viability obtainable. Acridine orange was used to prelabel acidic cell compartments, including lysosomes of macrophages cultured on coverslips[19]. One hour after infection, 80% of live *Toxoplasma*-containing vacuoles blocked fusion of acridine orange-labelled vesicles in normal macrophages. However, 86% of heat-killed (60 °C for 10 min) or antibody (heat-inactivated)-coated live *Toxoplasma* vacuoles fused with acridine orange-labelled vesicles within 1 h of phagocytosis by normal macrophages. In activated macrophages from immune mice[9] which were cultured *in vitro* for 8 h, 85% of live *Toxoplasma* vacuoles fused with acridine orange compartments, were digested, and thus resemble heat-killed or antibody-coated *Toxoplasma* vacuoles.

To evaluate the cidal effect of acidic *p*H, extracellular *Toxoplasma* were incubated in media at fixed *p*H values and then evaluated for their ability to survive in host cells. The viability of live *Toxoplasma* was reduced to $\leq$60% of control after incubation in media at *p*H 6.0, as evaluated by plaque formation on fibroblast monolayers[20] and fusion with acridine orange-labelled vesicles in normal macrophages (Fig. 1).

Having established the high susceptibility of extracellular *Toxoplasma* to acidic *p*H, we examined the *in situ p*H of modified

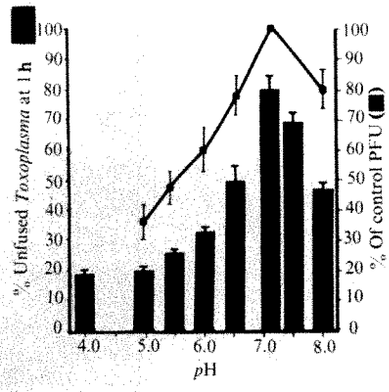

Fig. 1 Viability of *Toxoplasma* as evaluated by ability to block fusion of acidic vesicles (labelled with acridine orange) in macrophages (bars) and plaque formation on fibroblast monolayers (line) (expressed as plaque-forming units, PFU). Significant reduction in *Toxoplasma* viability was observed by both methods when extracellular *Toxoplasma* were exposed to media of *p*H 6.0.

Methods. RH strain *Toxoplasma* tachizoites (asexually replicating stages from acute infections in mice) were collected in Hank's balanced salt solution (HBSS) *p*H 7.2 (ref. 18). After 10 min incubation in isotonic HBSS adjusted to *p*H values from 4.0 to 8.0 (Orion Research millivolt *p*H meter 611), *Toxoplasma* were returned to HBSS at *p*H 7.2 and used for viability assays within 30 min. Normal mouse peritoneal macrophages were cultured in endotoxin-free ($\leq$0.01 ng ml^{-1}, Limulus Amebocyte Assay, Associates of Cap Cod Inc.) RPMI-1640 with 10% heat-inactivated fetal calf serum (CRMPI, Gibco) on 12-mm-diameter glass coverslips in 24-well plates for 18 h before use. The extent of fusion in normal macrophages labelled with acridine orange[19] was evaluated 1 h after *Toxoplasma* infection ($n = 3$)[25]. Plaque formation on human fibroblast monolayers[20] was evaluated after 7 days and expressed as mean % control (*p*H 7.2) from triplicate 25-cm^2 flasks.

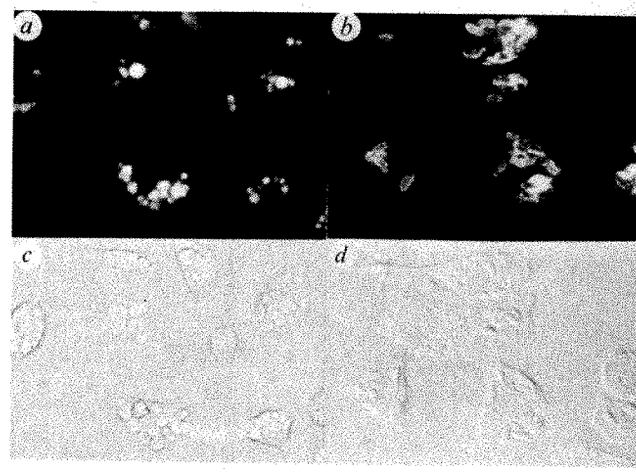

Fig. 2 Macrophage monolayers containing fluorescein-labelled *Toxoplasma*-containing vacuoles photographed on a Leitz Ortholux II epifluorescence microscope using a Nikon HFX 35-mm camera on Kodak Tri-X panchromatic film. *a*, Epifluorescence; *b*, phase contrast; *c*, epifluorescence; *d*, differential interference contrast. Monolayers were pulsed for 5 min with live or heat-killed *Toxoplasma* in CRPMI containing 2 mg ml^{-1} fluorescein dextran (relative molecular mass 20,000; Sigma), rinsed extensively in phosphate-buffered saline (PBS) and recultured. Approximately 80% of phagocytic vacuoles contained visible fluorescein dextran which did not affect block of acridine orange-labelled vesicle fusion or *Toxoplasma* replication in normal macrophages. Spectrofluorometry measurements indicated that pinocytosis of fluorescein dextran accounted for 10% of the total label internalized during *Toxoplasma* infection. *Toxoplasma* labelled with rabbit IgG and FITC-goat anti-rabbit (Sigma) were internalized by macrophage monolayers during 1 min infection challenge.

and heat-killed or antibody-coated *Toxoplasma* vacuoles in macrophage monolayers. *In situ* *p*H measurements were estimated from a standard curve relating fluorescence intensity (I_0) of intracellular fluorescein-labelled *Toxoplasma* to fixed *p*H values (s.e. = $\pm$0.15 unit; see Fig. 3*a* legend). The excitation spectrum of fluorescein is sensitive to *p*H changes between 4.0 and 8.0 and is independent of fluorochrome concentration when expressed as the I_0 (520 nm) ratio of excitation at 495/450 nm (ref. 21).

Modified live *Toxoplasma*-containing vacuoles were labelled using the fluid phase marker fluorescein dextran present in the media during infection with *Toxoplasma* (Fig. 2*a*, *b*). Normal macrophage monolayers containing modified vacuoles labelled with fluorescein dextran showed a slight decrease in I_0 during the first hour after infection (Fig. 3*b*). This slight acidification from *p*H 7.2 to 6.8 is probably due to the 20% of *Toxoplasma* which fuse with acidic cell compartments and the small amount of fluorescein dextran pinocytosed by macrophages during infection (see Fig. 2 legend). Most fluorescein dextran in the modified vacuoles did not undergo decreases in I_0, demonstrating that live *Toxoplasma* reside in neutral *p*H vacuoles.

The acidification of heat-killed or antibody-coated *Toxoplasma* vacuoles, which are destined to fuse with lysosomes, was evaluated in macrophages challenged with either heat-killed *Toxoplasma* in the presence of fluorescein dextran (Fig. 2*a*, *b*) or fluorescein isothiocyanate (FITC)-antibody-coated *Toxoplasma* (Fig. 2*c*, *d*). Normal macrophage vacuoles containing heat-killed *Toxoplasma* and fluorescein dextran underwent an extensive fall in *p*H from 7.2 to 5.2 after 1 h (Fig. 3*b*). Consistent with their intracellular fate, a similar rapid acidification of these vacuoles was observed with FITC-antibody-coated live *Toxoplasma* in normal macrophages (Fig. 3*b*). Of considerable interest, live *Toxoplasma* labelled with fluorescein dextran underwent a rapid acidification in activated macrophages (Fig. 3*b*). We did not detect the previously reported transient alkalinization to *p*H 7.4 at 2–3 min post-phagocytosis, although this may be because we used external media at *p*H 7.2 rather than 6.8 (ref. 6).

The kinetics of acidification of heat-killed or antibody-coated *Toxoplasma* vacuoles (Fig. 3*b*) indicates that a rapid shift to acidic *p*H is initiated within the first 3–5 min, starting from *p*H 7.2 and falling to *p*H 5.6 at 15 min post-phagocytosis. This rapid acidification rate appears similar to that of other reports on phagosomes of macrophages[6] and *Amoeba*[22]. During the initial 15 min post-phagocytosis, the rate of *p*H change in phagosomes is significantly higher than the rate of fusion with acidic compartments prelabelled with acridine orange (Fig. 4). At 15 min, when acidification is 70% complete, 65% of the vacuoles still show no evidence of acridine orange vesicle fusion (Fig. 4). This pattern is consistent with the model that phagocytic vacuole acidification precedes fusion with other acidic vesicles, including lysosomes[8].

Several mechanisms may be involved in the rapid acidification of compartments of heat-killed or antibody-coated *Toxoplasma* vacuoles. First, acidification may represent fusion of cytoplasmic vesicles which deliver proton-pumping ability to the phagosome, such as acidisomes described in *Paramecium*[23]. However, this explanation would only fit the data in Fig. 4 if the delivery vesicles are not active before vacuole fusion and thus not labelled with acridine orange. In this case, the failure of acidification of live *Toxoplasma* vacuoles represents a block of delivery-vesicle fusion. Alternatively, the observed differences in acidification may result from the degree of endogenous NADPH-oxidase and Mg-ATPase H^+-ion pump activity within the phagosome.

We have demonstrated here that live *Toxoplasma*-containing vacuoles show little capacity for acidification whereas both

antibody-coated and heat-killed *Toxoplasma* are internalized by normal macrophages into phagocytic vacuoles with an inherent ability to acidify. Activated macrophages challenged with live *Toxoplasma* also form phagocytic vacuoles with a marked ability to acidify. Similarly, the entry of live *Toxoplasma* into normal macrophages does not stimulate the oxygen radical production which is typical of phagocytosis of antibody-coated *Toxoplasma* by normal macrophages and of live *Toxoplasma* phagocytosed by activated macrophages[18]. These two observations suggest that differences in plasma membrane enzyme activation during formation of live as opposed to heat-killed or antibody-coated *Toxoplasma* vacuoles are responsible for their ultimate intracellular fate.

Although Fc and C3b receptors may trigger acidification during phagocytosis of antibody-coated *Toxoplasma*, acidification resulting from ingestion of heat-killed *Toxoplasma* by normal macrophages and live *Toxoplasma* by activated macrophages must be initiated by an alternative receptor, as antibody was not present in these preparations. Initiation is either not triggered when live *Toxoplasma* enter normal macrophages, or is inhibited, as demonstrated by the failure of modified live *Toxoplasma*-containing phagosomes to acidify. A similar pattern of variable extent of endosome acidification occurs in ligand-receptor endosomes, where *p*H values range from 6.4 to 5.0 depending on the receptor involved[12–15]. Although *Toxoplasma* show a specific attachment phase before entry[2–4], neither the receptor involved in this step nor the distribution of other cell-surface receptors within the phagosome have been characterized.

The significance of phagosome acidification to intracellular *Toxoplasma* is paramount to survival, judging from their high susceptibility to mild acidic conditions when they are extracellular. Thus, the failure of acidification exhibited by live *Toxoplasma*-containing vacuoles in normal macrophages enables *Toxoplasma* to survive within cells normally considered microbicidal. In support of this hypothesis, two other intracellular parasites which resist lysosome fusion have been shown to reside in neutral (*p*H = 6.9)[7] or weakly acidic (*p*H 6.1)[24] compartments in normal macrophages. Increased capacity for phagosome acidification in activated macrophages and in normal macrophages in the presence of specific antibody probably contributes to the destruction of intracellular *Toxoplasma*.

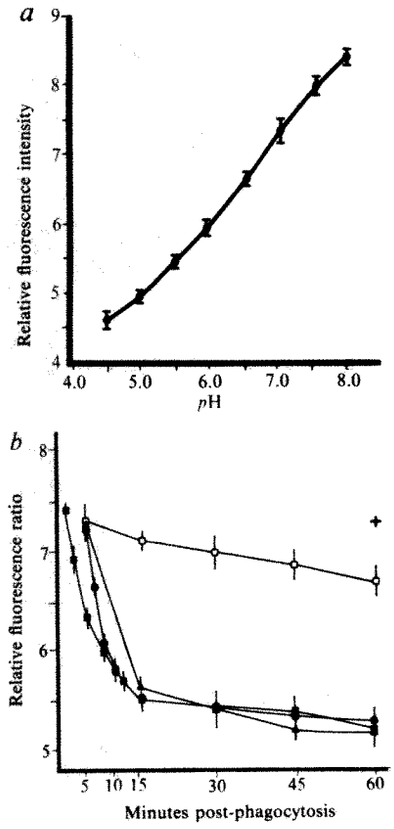

Fig. 3 *a*, *In situ* standard curve relating fluorescence intensity (I_0) ratio of intracellular FITC-labelled *Toxoplasma* to fixed *p*H values. *b*, Fluorescence intensity ratios from macrophage monolayers containing fluorescein-labelled *Toxoplasma* vacuoles at intervals after phagocytosis. A decrease in I_0 represents a shift in the intravacuolar *p*H to acidic conditions (*a*). A slight decline in I_0 is evident during the first hour after infection from modified live *Toxoplasma*-containing vacuoles in normal macrophages (□), probably due to the 20% of *Toxoplasma* in this preparation which fuse with acidic vesicles. In contrast, a rapid decrease in I_0 is observed from macrophage vacuoles containing heat-killed *Toxoplasma* and fluorescein dextran (▲), and FITC-antibody-labelled live *Toxoplasma* (■) in normal macrophages and from live *Toxoplasma* and fluorescein dextran (●) in activated macrophages.
Methods. *a*, Macrophage monolayers containing FITC-*Toxoplasma* (see Fig. 2*a*, *b*) were incubated in sodium citrate (*p*H 4.0, 4.5, 5.0) or PBS (*p*H 5.5, 6.0, 6.5, 7.0, 7.5, 8.0) containing 10 μm monensin to collapse cell *p*H gradients and clamp intracellular compartments at the fixed *p*H of the external buffer. Fluorescence intensity was recorded from macrophages attached to coverslips placed in 1-cm cuvettes using an Aminco-Bowman spectrofluorometer with 10-nm bandwidth excitation (altered between 450 and 495) and 5-nm bandwidth emission centred at 520 nm, $n = 6$ (ref. 21). Correction for background scatter and autofluorescence was made by subtraction of I_0 readings from a similar set of monolayers which did not contain fluorescein. *b*, Infected macrophages labelled with fluorescein (cell density 2×10^6 per coverslip; 2–5 *Toxoplasma* per host cell) were rinsed in PBS and I_0 recorded in PBS at 37 °C. Corrected values were obtained by subtracting background fluorescence readings from unlabelled infected monolayers. A separate set of three coverslips was used to determine mean I_0 ratio for each time point. Intracellular acidification of heat-killed or antibody-coated *Toxoplasma*-containing vacuoles was reversible by addition of 10 μM monensin in PBS at *p*H 7.2 (+), but was not affected by changes in external buffer *p*H in the absence of ionophore.

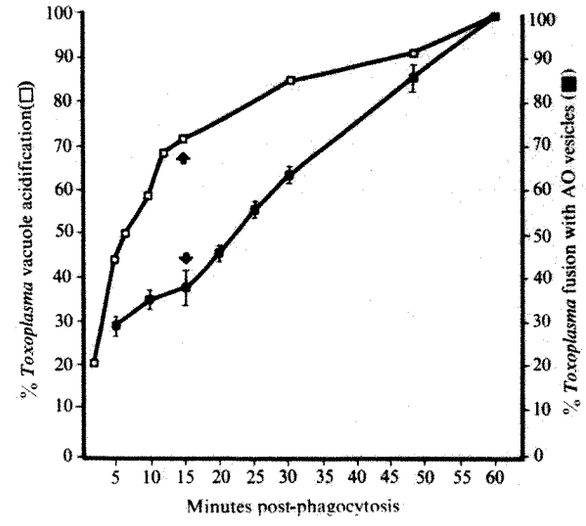

Fig. 4 Comparison of the rate of fusion of acidic vesicle (labelled with acridine orange, AO) (■) with *p*H changes (□) in normal macrophage containing heat-killed or antibody-coated *Toxoplasma*. Most acidification occurs before the fusion of acidic vesicles including lysosomes. The % of total acidification is calculated from I_0 data points in Fig. 3*b* representing FITC-labelled *Toxoplasma* ingested during a 1-min pulse. The extent of acidic vesicle fusion was obtained from normal macrophages labelled with acridine orange and challenged similarly with FITC-*Toxoplasma*. Three separate coverslips were used to score each time point. Similar kinetic curves for fusion rate were obtained with heat-killed *Toxoplasma* in normal macrophages and live *Toxoplasma* in activated macrophages.

We thank Dr Jack Remington for providing *Toxoplasma* strains and Dr Elmer Pfefferkorn for fibroblast cultures. This work was supported in part by a Grant-in-Aid of Research from Sigma Xi, the Scientific Research Society and NIAID research grant AI22442-01.

Mitogens trigger a calcium-independent signal for proliferation in phorbol-ester-treated lymphocytes

Erwin W. Gelfand, Roy K. Cheung, Gordon B. Mills & Sergio Grinstein

Divisions of Immunology/Rheumatology and Cell Biology, Research Institute, Hospital for Sick Children, Toronto, Canada M5G 1X8

The activation of T lymphocytes by mitogens requires at least two signals; the first, delivered to T cells by a mitogen in conjunction with accessory cells (monocytes/macrophages), leads to the generation of the second signal, interleukin-2 (IL-2). The first signal also induces the expression of IL-2 receptors on the surface of a subpopulation of T cells; binding of IL-2 to its receptor then initiates a cascade of events culminating in DNA synthesis by these cells[1-4]. Certain compounds act synergistically with mitogens in promoting T-cell proliferation by substituting for the activities of interacting cells or their products. For example, the phorbol ester 12-*O*-tetradecanoyl phorbol 13-acetate (TPA) has been shown to restore the ability of macrophage-depleted T-cell populations to respond to mitogenic lectins[5-7]. Transmembrane fluxes of calcium, leading to increased free cytosolic calcium concentrations ($[Ca^{2+}]_i$), have been demonstrated following mitogen binding to lymphocytes and have been implicated in the initiation of cell proliferation[8-10]. We show here that the effect of TPA on lymphocyte proliferation occurs in the absence of extracellular Ca^{2+} or detectable changes in $[Ca^{2+}]_i$, but only in the presence of mitogens. This suggests that in cells which have been incubated with the phorbol ester, mitogens can induce proliferation by a calcium-independent signal.

Mitogenic lectins such as phytohaemagglutin (PHA) and concanavalin A, and non-mitogenic lectins such as wheat germ agglutinin, lead to a rapid rise in $[Ca^{2+}]_i$ even when there is no proliferative response[9], and this hampers attempts to evaluate the requirement for an increase in $[Ca^{2+}]_i$ in the initiation of cell proliferation. However, we have shown previously that, in contrast to PHA-induced activation of monocyte-depleted human T cells, the T-cell mitogen[11] protein A (SpA from *Staphylcoccus aureus*, Cowan I strain) does not produce changes in $[Ca^{2+}]_i$ or DNA synthesis in the absence of monocytes[12]. Monocytes preincubated with SpA trigger a rapid increase in $[Ca^{2+}]_i$ as well as a proliferative response in these isolated T cells. We therefore used this sytem to determine whether TPA can serve as a co-mitogen and whether the effect of TPA on SpA-induced proliferation of isolated human T cells (in the absence of monocytes) requires, or is accompanied by, changes in $[Ca^{2+}]_i$.

Table 1 illustrates the effects of PHA and SpA on $[Ca^{2+}]_i$ monitored by quin 2 fluorescence during the first 24 h and by the proliferative response measured using ^{3}H-thymidine incorporation at 72 h. Incubation of a mixed population of peripheral blood mononuclear cells (PBM) with PHA or SpA resulted in significant incorporation of ^{3}H-thymidine and increases in $[Ca^{2+}]_i$. The response to PHA was rapid, $[Ca^{2+}]_i$ more than doubling within 10 min, then falling progressively and reaching

Table 1 Mitogen-dependent effects on levels of cytoplasmic Ca^{2+} and lymphocyte proliferation

	$[Ca^{2+}]_i$ (nM)				^{3}H-thymidine incorporation (c.p.m.)
	0	10 min	3 h	24 h	
PBM + PHA	108 ± 2.0	235 ± 8.0	187 ± 7.4	114 ± 3.1	44,090 ± 2,670
PBM + SpA	110 ± 2.7	128 ± 12.4	180 ± 5.5	114 ± 3.8	22,165 ± 1,860
E^+ + PHA	106 ± 2.0	245 ± 7.8	186 ± 2.4	116 ± 3.5	62,210 ± 2,110
E^+ + SpA	106 ± 2.4	110 ± 5.3	113 ± 3.4	114 ± 3.0	4,520 ± 760

Peripheral blood mononuclear cells (PBM) were isolated following Ficoll-Hypaque gradient centrifugation. Erythrocyte-rosetting T cells (E^+) were obtained by rosette enrichment as described elsewhere[23]. Cells (200 μl, 5×10^5 ml^{-1}) were cultured with PHA (10 μg ml^{-1}, Difco) or SpA (100 μg ml^{-1}, Pharmacia for 72 h in RPMI-1640 containing 10% fetal calf serum. Four hours before the end of the culture, 1 μCi ^{3}H-thymidine (6.7 Ci mmol^{-1}) was added; labelled DNA was counted in a liquid scintillation counter. The mitogens were added at time 0 and $[Ca^{2+}]_i$ levels recorded at 10 min, 3 h and 24 h. For monitoring $[Ca^{2+}]_i$, 10×10^6 cells ml^{-1} were incubated with 10 μM acetoxymethyl quin-2 (generously provided by Dr T. J. Rink, and prepared as a 2 mM stock solution in dimethyl sulphoxide) as described previously[10]. The cells were incubated with quin-2 before each assay point. A Perkin-Elmer spectrofluorimeter (Model 650-40) was used for fluorescence measurements, for which the cells were suspended in HEPES-buffered saline containing 1 mM Ca^{2+} (ref. 10). Calculation of free cytosolic Ca^{2+} concentration ($[Ca^{2+}]_i$) was as described previously[10,24]. Although reported to affect the response of lymphocytes to mitogen[9], the concentration of quin-2 used here was shown to be non-mitogenic and did not significantly interfere with mitogen-induced proliferation. Results represent the means ±s.e.m. of three separate experiments carried out in duplicate (Ca^{2+} determinations) or triplicate (^{3}H-thymidine incorporation). In the absence of mitogen, background c.p.m. were <1,000 and $[Ca^{2+}]_i$ was 106-112 nM.

Table 2 TPA modulation of mitogen-induced changes in levels of cytosolic free Ca^{2+} and lymphocyte proliferation

	$[Ca^{2+}]_i$ (nM)				^{3}H-thymidine incorporation (c.p.m.)
	0	10 min	3 h	24 h	
TPA (16 h)	112 ± 3.0	112 ± 3.2	110 ± 2.5	112 ± 2.5	3,100 ± 270
PHA	111 ± 2.3	236 ± 5.6	191 ± 5.3	—	40,530 ± 1,350
TPA (16 h) →PHA	108 ± 1.2	246 ± 7.6	204 ± 4.2	—	52,400 ± 5,790
PHA	114 ± 3.2	260 ± 6.2	201 ± 3.2	118 ± 4.6	34,870 ± 2,480
TPA (1 h) →PHA	108 ± 3.2	256 ± 8.2	202 ± 3.5	120 ± 5.2	47,980 ± 2,870
SpA	109 ± 2.4	112 ± 1.6	112 ± 4.0	—	4,040 ± 670
TPA (16 h) →SpA	112 ± 1.5	120 ± 5.6	115 ± 5.1	—	23,110 ± 3,160
SpA	105 ± 3.2	110 ± 6.4	116 ± 6.2	114 ± 5.2	2,250 ± 690
TPA (1 h) →SpA	116 ± 2.1	118 ± 2.6	120 ± 3.6	122 ± 5.2	20,570 ± 1,160

Human E-rosetting T cells (10×10^6 ml^{-1}) were incubated with TPA (10^{-9} M) (Sigma) for 1 or 16 h in RPMI-1640 plus 10% fetal calf serum. The cells were then washed three times in RPMI containing defatted bovine serum albumin (BSA, Sigma) and twice with RPMI to remove residual TPA[25]. Aliquots of the cells were then either loaded with quin-2 for $[Ca^{2+}]_i$ determinations or used in studies of lymphocyte proliferation (see Table 1). Results represent the means ±s.e.m. of three separate experiments.

Table 3 Mitogen-dependent changes observed in the presence of EGTA

Expt *a*

Initial incubation	Second incubation	^{3}H-thymidine incorporation (c.p.m.)
Medium	Medium	1,100 ± 200

Medium	PHA	22,840 ± 3,240
Medium	TPA → PHA	25,110 ± 2,910
EGTA	TPA	2,190 ± 270
EGTA	PHA	4,220 ± 730
EGTA	TPA → PHA	24,790 ± 2,720
Medium	SpA	4,570 ± 660
Medium	TPA → SpA	16,200 ± 570
EGTA	SpA	5,870 ± 320
EGTA	TPA → SpA	18,500 ± 1,080

Expt *b*

	$[Ca^{2+}]_i$ (nM)		
Initial incubation	Second incubation		
Medium	106 ± 2.0	PHA	245 ± 7.8
Medium	112 ± 3.0	TPA	112 ± 3.2
TPA	108 ± 3.2	PHA	256 ± 8.2
EGTA	102 ± 6.6	TPA	103 ± 5.2
EGTA	105 ± 3.0	PHA	107 ± 2.8
EGTA → TPA	108 ± 2.6	PHA	108 ± 3.2

E-rosetting T cells were used in these studies. Expt *a*): Determination of ^{3}H-thymidine incorporation. In the initial incubation, 5×10^5 cells ml^{-1} were incubated with medium containing EGTA (2 mM) or medium (RPMI-1640) alone for 30 min at 37 °C. In the second incubation, TPA (10^{-9} M) was added where indicated for 1 h, followed by the addition of mitogen for 1 h at 37 °C. Only then were the cells washed three times with RPMI-containing defatted BSA and twice in RPMI. Aliquots (200 μl) of cells (5×10^5 ml^{-1}) were then incubated for 72 h in RPMI-1640 plus 10% fetal calf serum. Previous studies have shown that a 1-h incubation with PHA, followed by cell washing, results in 80–90% of the proliferative response observed when PHA is left in culture for the entire 72 h[16]. Results represent the means ±s.e.m. of three experiments carried out in triplicate. Expt *b*: Determination of $[Ca^{2+}]_i$ levels. Initial incubation: cells were first incubated with quin-2 (10 μM) for 60 min, washed, then incubated with medium containing EGTA (2 mM) or medium only (see Table 1) for 30 min at 37 °C. TPA (10^{-9} M) was then added for 1 h as indicated. Baseline levels of $[Ca^{2+}]_i$ were obtained. In the second incubation, PHA (or TPA) was added and $[Ca^{2+}]_i$ levels determined 10 min later. Results represent the means ±s.e.m. of three separate experiments carried out in duplicate.

baseline levels after 24 h. The response to SpA was somewhat slower, with a period of 2–3 h required to reach maximum $[Ca^{2+}]_i$ levels. This delay probably reflects the requirement for monocyte/T-cell interaction in the response to SpA[12]. Purified T cells (E^+) respond to PHA in a similar manner to the unfractionated PBM, with both a rapid increase in $[Ca^{2+}]_i$ and a greater proliferative response. In contrast, as previously reported[12], incubation of purified T cells with SpA resulted in a greatly reduced ^{3}H-thymidine incorporation and no significant change in $[Ca^{2+}]_i$.

TPA is the most potent of the group of phorbol diesters known to promote tumours or induce cellular differentiation[13]. By itself, TPA (10^{-9} M) is weakly mitogenic but does not lead to changes in $[Ca^{2+}]_i$ (ref. 8 and Table 2). We found that preincubation of cells with TPA for 1 or 16 h, followed by the addition of PHA, produced a greater proliferative response than observed with cells not preincubated with TPA. The increase in cytosolic free Ca^{2+} following addition of PHA was similar with or without TPA pretreatment.

When purified T cells were incubated with TPA for 1 or 16 h, they subsequently exhibited a proliferative response to SpA (Table 2); the magnitude of ^{3}H-thymidine incorporation was similar to that seen with PBM (Table 1). In the presence of SpA, $[Ca^{2+}]_i$ levels were only marginally higher in cells preincubated with TPA than in cells exposed to SpA alone; monitoring of $[Ca^{2+}]_i$ indicated little change in levels during the 24-h period following addition of SpA. These results indicate that preincubation enables T cells to proliferate in response to SpA without an accompanying rise in $[Ca^{2+}]_i$.

In monocyte-dependent systems, TPA can often restore the proliferative response to mitogens in monocyte-depleted cell populations[4–6]. Although TPA can augment the production of interleukin-1 (a monocyte-derived lymphokine)[14,15] the effects of TPA described in Table 2 are monocyte-independent and the drug seems to act directly on purified T cells. These effects of TPA on SpA-induced T-cell proliferation can be easily distinguished from those observed following addition of monocytes; in the presence of monocytes, $[Ca^{2+}]_i$ increased significantly (Table 1, PBM) whereas with TPA pretreatment of purified T cells there was little deviation from baseline $[Ca^{2+}]_i$ following the addition of SpA (Table 2).

We have shown previously that triggering of a PHA-induced proliferative response is dependent on the presence of extracellular Ca^{2+} (ref. 16). We therefore investigated whether TPA treatment would produce a PHA-induced proliferative response in the absence of raised $[Ca^{2+}]_i$. We found that, in contrast to cells in Ca^{2+}-containing medium, T lymphocytes treated with the Ca^{2+} chelator EGTA and then incubated with PHA for 1 h in EGTA-containing medium, failed to incorporate ^{3}H-thymidine when returned to normal (and lectin-free) medium for the remaining 72 h (Table 3, expt *a* and ref. 16). Cells treated similarly, except for preincubation with TPA, demonstrated a response to PHA (and SpA). As the TPA preincubation was carried out with EGTA-treated cells in EGTA-containing medium, this result suggests that the TPA effects do not require extracellular Ca^{2+}, in contrast to previous reports[17]. Cells pretreated with EGTA and incubated with TPA and PHA in EGTA-containing medium showed no increase in $[Ca^{2+}]_i$ (Table 3, expt *b*), but did show an increase in ^{3}H-thymidine incorporation (Table 3, expt *a*).

The importance of increases in Ca^{2+} as a signal for mitogen-induced proliferation has been demonstrated in several different systems (reviewed in ref. 18), although the nature of the Ca^{2+} signal and the target for its activity are unknown. On the other hand, TPA is known to be co-mitogenic for lymphocytes and may act by directly activating protein kinase C, leading to protein phosphorylation[19–22]. The present report, as well as previous studies[8], have shown that TPA does not mobilize Ca^{2+} as measured directly using the fluorescent indicator quin-2. We used two independent systems, one in which changes in $[Ca^{2+}]_i$ do not occur in response to mitogen alone and one in which changes in $[Ca^{2+}]_i$ were prevented by the presence of EGTA. In both systems, following treatment with TPA, T lymphocytes become able to proliferate in response to mitogens. As TPA, an activator of protein kinase C, is itself non-mitogenic, this suggests that another, calcium-independent, signal can be generated by the mitogen; the nature of this signal remains to be elucidated.

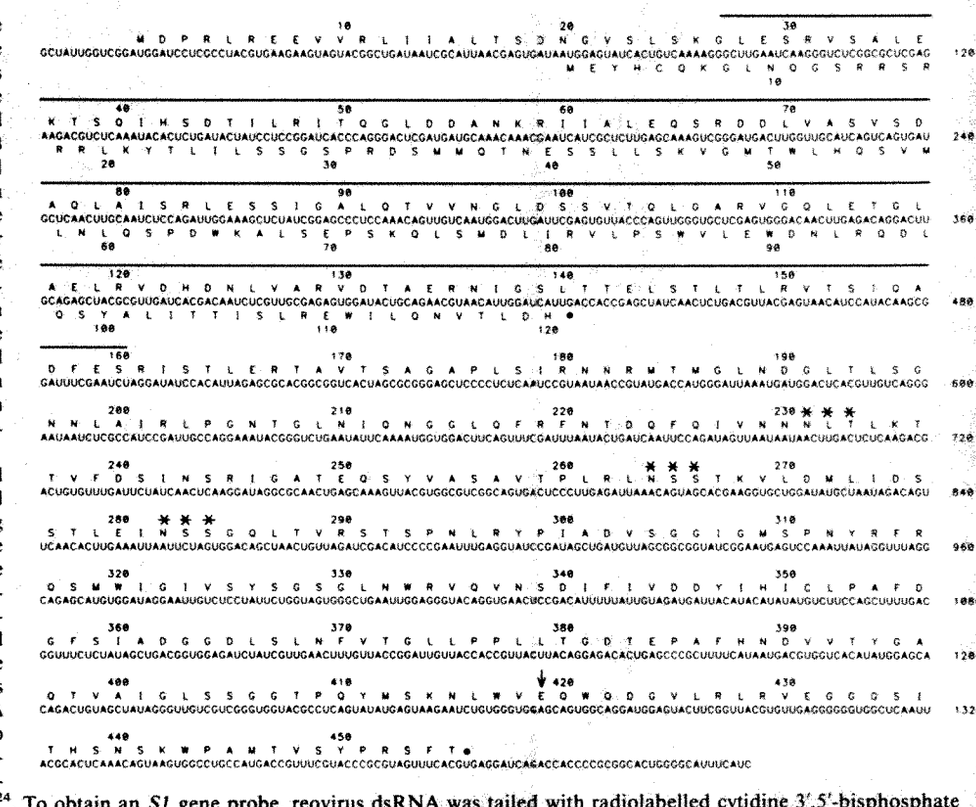
The use of modern techniques has led to new insights into the molecular mechanisms of viral pathogenesis[1]. Although the infectious process is quite complex, it is clear that one critical stage, the interaction of viral attachment proteins with cell-surface receptors, often has a major role in determining the pattern of infection[2]. The mammalian reoviruses have served as useful models for understanding the molecular basis of viral pathogenesis[2]. The mammalian reovirus haemagglutinin (σ1 protein), which is an outer capsid protein, has been shown to be a major factor in determining virus–host cell interactions[2]. To further our understanding of the structure and function of the haemagglutinin, we have cloned a complementary DNA copy of the reovirus type 3 *S1* double-stranded RNA gene which encodes the virus haemagglutinin and have sequenced the DNA complementary to the *S1* gene. Analysis of the predicted amino-acid sequence of the virus haemagglutinin has allowed us to determine that the amino-terminal portion contains an α-helical coiled-coil structure and that the carboxy-terminal portion contains the receptor-interacting domains. Using this information, we propose here a model of how the reovirus haemagglutinin is attached to the virus particle.

Figure 1 shows the nucleotide sequence of the entire reovirus type 3 *S1* gene. The gene consists of 1,416 nucleotide bases and has two open reading frames. The first open reading frame begins at nucleotide 13 and terminates at nucleotide 1,377, encoding a protein of 455 amino acids and computed relative molecular mass of 49,071. This protein corresponds to the reovirus haemagglutinin (σ1 protein) as determined by the previously estimated sizes[3,4].

The predicted amino-acid sequence of the virus haemagglutinin contains three potential glycosylation sites (see Fig. 1). Although it has been reported that the haemagglutinin of reovirus grown in the L strain of mouse fibroblasts can incorporate radiolabelled amino-sugars at a low level[5], there has been no confirmation that the three potential sites are glycosylated in the haemagglutinin.

A second open reading frame in the *S1* gene begins at nucleotide 71 and terminates at nucleotide 430 and would encode a polypeptide of 120 amino acids. The presence of two open reading frames agrees with both ribosome binding studies[6] and *in vitro* translation studies[7] which conclude that the *S1* gene has two initiation sites. Recently, the 120-amino-acid protein has been detected in reovirus-infected cells[8].

Examinations of the amino-acid sequence of the reovirus type 3 haemagglutinin reveals certain features, in particular, a heptapeptide repeat pattern (*a–b–c–d–e–f–g*) between amino acids 28 and 158, representing approximately one-third of the molecule at the amino-terminal end. In this pattern, amino acids at positions *a* and *d* are primarily hydrophobic (Table 1). Another striking feature of the sequence is that there are two proline residues flanking this heptapeptide repeat at amino acid positions 3 and 176, but no prolines within the heptapeptide repeat pattern. The heptapeptide repeat, the position of the hydrophobic amino acid and the absence of both proline and aromatic amino acids from the heptapeptide repeat are typical of an α-helical coiled-coil structure where the hydrophobic residues at positions *a* and *d* form the interface between the α-helices[9,10]; this agrees with computer analysis of protein secondary-structure predictions[11] which shows this area to



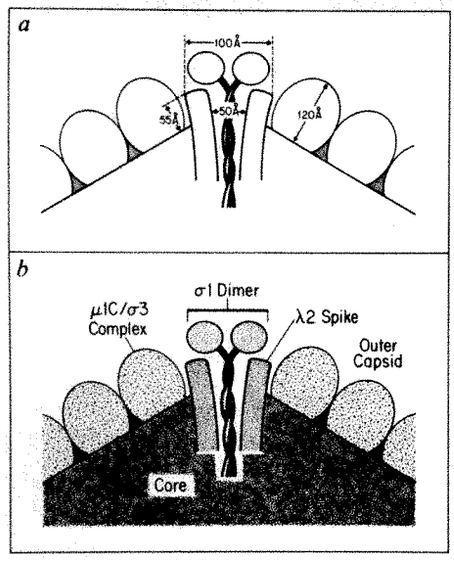


Fig. 1 The determined nucleotide sequence of reovirus type 3 *S1* gene and predicted amino-acid sequences for both open reading frames. The one-letter amino-acid notation used is recommenced by the IUPAC-IUB Commission on Biochemical Nomenclature[22]. The numbers given above the amino-acid sequence designate the residue positions for the first open reading frame. The numbers on the right show nucleotide positions. The α-helical region is indicated by a thick line above the amino-acid residues. The potential glycosylation sites are marked by an asterisk. The mutation site for an immune-selected variant (K) is indicated by an arrow.

Methods. Genomic double-stranded (ds) RNA was isolated from purified reovirus type 3 (Dearing) and, using the enzyme poly(A) polymerase (BRL), ~30 AMP molecules were added to the 3′ termini[23]. The polyadenylated RNA was used as a template to synthesize oligo(dT)-primed single-stranded (ss) cDNA[24]. The complementary ss cDNA fragments were hybridized to obtain ds cDNA fragments which were inserted into pBR322 by G-C tailing[25]. The recombinant plasmids were used to transform *Escherichia coli* MC1061 cells[24]. To obtain an *S1* gene probe, reovirus dsRNA was tailed with radiolabelled cytidine 3′,5′-bisphosphate using T_4 RNA ligase[26]. The radiolabelled *S1* dsRNA was then used to screen the cDNA library. A full-length cDNA clone of the *S1* gene was isolated. Restriction enzyme fragments for this cDNA clone were ligated into bacteriophage vector M13 mp9 RF-DNA[27] and sequenced by the dideoxy-chain terminator method[28].

The α-helical region is shown to extend through the $\lambda 2$ channel into the viral core. The globular-like structure sits on top of the $\lambda 2$ channel and interacts with host cell receptors. *c*, Summary of structure-function of the virus haemagglutinin.

consist of an α-helical structure. Similar predictions of a coiled-coil structure based on sequence data and computer analysis were reported for the influenza virus haemagglutinin[12]. This structure was subsequently verified by crystallography and shown to represent ~23% of the polypeptide that provides the major force stabilizing the trimeric subunit interactions[13].

By definition, the α-helices of a coiled-coil structure are wound around each other; this predicts at least a dimer form for the reovirus haemagglutinin. Studies show that there are 24 haemagglutinin molecules per virion which are located on the 12 projections/spikes on the outer capsid[14]. Thus, both the stoichiometry and the coiled-coil structure support a dimer form for the haemagglutinin.

In contrast to the amino-terminal portion, the carboxy-terminal portion of the virus haemagglutinin shows no dominant structural pattern. Computer analysis of protein secondary-structure predictions[11] show that this area is a mixture of short α-helices, β-sheets and random coils and that it contains many turns. This area also contains 12 proline residues and bulky aromatic amino acids, unlike the α-helical amino-terminal portion. All these features suggest a globular-like structure at the carboxy-terminal portion of the haemagglutinin protein.

Recent studies on a reovirus variant strain (designated variant K)[15] have localized the receptor-binding region to the carboxy terminus of the virus haemagglutinin (R.B.-D., unpublished data). In particlar, the *S1* gene of this immune-selected variant, in which the receptor-binding site is altered[16], is similar to the *S1* gene of reovirus type 3; the only nucleotide base change in the variant *S1* gene is a point mutation at nucleotide 1,267 (corresponding to a change in amino acid 419 from glutamic acid to lysine). Thus, the receptor-binding site is in the carboxy-terminal portion of the haemagglutinin protein.

The protein sequence of the reovirus haemagglutinin was compared with all the protein sequences available in the National Biomedical Research Foundation database, using the Goad–Kanehisa program for finding local homologies[17]. Significantly high scores (8 and 7 s.d.) were obtained with nematode myosin and rabbit tropomyosin. Optimal alignment of reovirus haemagglutinin (amino acids 27–100) and nematode myosin (amino acids 1,391–1,464) gives an average of 28% identical residues. When comparisons are based on grouping amino acids containing similar side chains, the extent of homology increases to an average of 51%. However, myosin[18] and tropomyosin[10] both consist of α-helical coiled-coil structures. To evaluate whether the observed homologies were due to evolutionary relatedness or structural relatedness, further computer analysis was performed on the homologies and revealed scores (4.5 and 4 s.d.) which indicated definite structural relatedness between reovirus haemagglutinin and myosin/tropomyosin. Because of the lack of any known functional similarities, the evolutionary relatedness of these proteins remains uncertain.

Figure 2 shows a model of the virus haemagglutinin and its orientation in the virus. Also shown are the known dimensions of the outer capsid, the location of the $\mu 1C/\sigma 3$ complex, the $\lambda 2$ projections/spikes and the channel within the $\lambda 2$ protein. Evidence that the haemagglutinin lies close to the $\lambda 2$ protein comes from analysis of extragenic suppressor mutations[19]. Temperature-sensitive (ts) mutants of reovirus containing defects in the $\lambda 2$ protein (tsB-352) revert to a non-ts phenotype with second mutations in the $\sigma 1$ protein. Such second-site mutations occur predominantly in proteins which share an intimate structural relationship. Further evidence for a close interaction between $\lambda 2$ and $\sigma 1$ proteins is the fact that although $\sigma 1$ protein is the major neutralization antigen, monoclonal antibodies against $\lambda 2$ protein also result in neutralization[20], presumably through steric hindrance of the $\sigma 1$ protein function.

The $\sigma 1$ protein has been drawn in the model as a dimer containing an extended α-helix whose length when fully extended is $\simeq$180 Å. Unlike the adenovirus fibre protein, which projects as an extended rod from the surface of the adenovirus core, no structure has been seen to project from the surface of

the reovirus particle. Therefore, the extended α-helix of the protein must be accommodated within the virion. The location of the haemagglutinin over the $\lambda 2$ channel makes it likely that the extended α-helical portion of the haemagglutinin extends into the channel, while the globular portion containing the receptor-interacting region is present on the outer surface of the virus particle. This model is consistent with the known channel diameter of the core spike (50 Å) and the radius of the outer capsid (120 Å)[21]. The location of the α-helix in the $\lambda 2$ channel would provide an anchor, attaching the $\sigma 1$ protein to the virus particle. Recent work in this laboratory on the morphology of the reovirion supports the proposed model (M. Nibert, unpublished data). The present studies should now make it possible to analyse, on a molecular level, the structure of the reovirus attachment protein and its interaction with its host cell receptor.

We thank Dr Kenneth Tyler and Max Nibert for discussions and comments; Drs Edmund Choi and Jonathan Seidman for help with DNA sequencing and for discussions; Dr Stephen Harrison for discussion; Dr Angus Graham for continuous support; and Elaine Freimont for technical assistance. This work was supported by NIAID, PHS research grant 5 R01 AI13178, with partial support from the Shipley Institute of Medicine and the MRC of Canada (N.S. and Dr Angus Graham). R.B.-D. is supported by FCAC (Gouvernement du Québec).

Note added in proof: Since the submission of this manuscript, two other laboratories have published the sequence of the reovirus type 3 *S1* gene[30,31].

An immunoglobulin promoter displays cell-type specificity independently of the enhancer

John Foster, Jeannine Stafford & Cary Queen

Laboratory of Biochemistry, National Cancer Institute, National Institutes of Health, Bethesda, Maryland 20205, USA

Recent studies in which cloned immunoglobulin genes were introduced into cultured cells have produced two significant findings. First, the genes are expressed after transfection into lymphoid cells but not non-lymphoid cells[1-3]. Second, transcription of an immunoglobulin gene requires, in addition to the promoter region, an enhancer element located downstream of the transcription start site[4-10]. These findings raise the question of whether it is the promoter or the enhancer region that is responsible for the observed cell-type specificity. It has, in fact, been shown that immunoglobulin enhancers function only in lymphoid cells[6,8,9]. We show here that the promoter for an immunoglobulin κ light-chain gene also is strongly specific for lymphoid cells. Our result re-emphasizes the importance of promoters relative to enhancers in determining which cells express which genes.

Because the κ light-chain enhancer is already known to be cell-type specific, any study of the specificity of the κ-chain promoter must separate the promoter from the enhancer. For this purpose, we constructed the plasmid pLX40 (Fig. 1*a*), which contains three important elements: (1) part of the MOPC 41 κ light-chain gene[11] extending from ~1.1 kilobases (kb) before the transcription initiation site to 2.1 kb after the initiation site; (2) the simian virus 40 (SV40) early promoter attached to the bacterial *neo* gene[12]; and (3) the polyoma virus large-T antigen gene and origin of replication. The part of the κ-chain gene used excludes the enhancer, which has been mapped[5] to a region 1.6 kb further downstream. The κ-chain gene polyadenylation signal, also deleted in this construction, is replaced by an SV40 poly(A) signal to allow processing of κ-chain transcripts into stable messenger RNA[4,5]. The role of the SV40 promoter is to provide an internal control for transcription from the κ-chain promoter. The polyoma segment allows the plasmid to replicate to a high level in most mouse lymphoid and non-lymphoid cell lines (ref. 13 and our unpublished data), thus increasing the amount of RNA synthesized by increasing the amount of DNA template[4,5,7].

The κ-chain promoter cannot function without an enhancer, and so, to study transcription from the promoter, we inserted three different enhancers into pLX40 at an upstream *Eco*RI site. A 238-base pair (bp) fragment of polyoma (nucleotides 5,028-5,265)[14] including the enhancer region[15] was inserted in both orientations to form the plasmids pLX40P.1 and pLX40P.2. A 216-bp fragment of the Moloney murine sarcoma virus (MSV) long terminal repeat (nucleotides 210-426)[16], containing the 73/72-bp repeat unit with full enhancer activity[16], was inserted to form the plasmid pLX40M.1. For purposes of comparison, a 473-bp fragment of the κ-chain gene (nucleotides 3,689-4,161)[17] containing the κ enhancer itself[5,6] was also inserted in both orientations to form the plasmids pLX40K.1 and pLX40K.2. Although pLX40 already contains the SV40 enhancer as part of the SV40 origin (Fig. 1*a*), we inserted the enhancers from murine viruses to obtain maximal activation of the κ-chain promoter in mouse cells[18,19]. In fact, pLX40 also contains the polyoma enhancer as part of the polyoma replicon, but the enhancer does not stimulate the κ-chain promoter in this configuration[4,5].

This set of six plasmids was transfected into antibody-secreting MPC 11 mouse myeloma cells and three lines of non-lymphoid mouse cells. Forty-eight hours after transfection, total RNA was extracted from the cells and assayed by the S_1 nuclease method[20,21] in conditions of probe excess. For each RNA sample, one aliquot was tested with a 5′ end-labelled, double-stranded probe specific for κ-chain transcripts and an equal aliquot with such a probe specific for *neo* transcripts (Fig. 1*b*). The two hybridizations were carried out at temperatures optimal for the respective probes, and the two S_1 nuclease-treated reactions combined before loading on a gel.

Figure 2 shows the results of a typical S_1 experiment after transfection of the plasmids into MPC 11 cells. Bands of the intact *neo* and κ probes were present (Fig. 2), because of some re-annealing of the probes during the hybridizations and to some upstream transcription from pBR322 sequences (data not shown). In addition, a strong band was present beneath the *neo* probe. The size of this fragment corresponds to transcripts

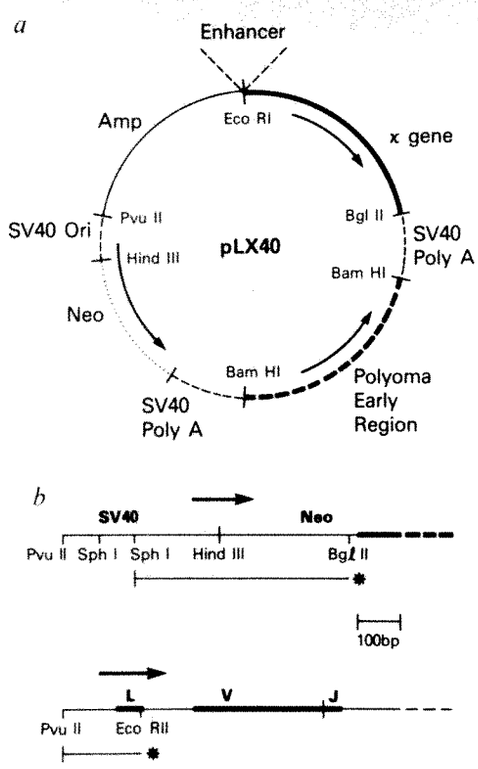

Fig. 1 *a*, Schematic diagram of the plasmid pLX40. Sources of DNA fragments are indicated as follows: pBR322, solid line; SV40, dashed line; *neo* gene, dotted line; polyomavirus, heavy dashed line; κ gene, heavy line. The structure of the pBR322-*neo*-SV40 segment is as described elsewhere[12]; the κ segment extends from the upstream *Eco*RI site to the *Bgl*II site in the intron[11,17]; the SV40 segment after the κ-chain gene is the same as the SV40 segment after the *neo* gene, and the polyoma segment is the same as used previously[4]. Arrows indicate the approximate initiation sites and directions of transcription for the SV40 early promoter, the polyoma early promoter and the κ promoter. Enhancers were inserted at the *Eco*RI site by means of linkers to form other plasmids. *b*, Strategy for S_1 nuclease assays. The *neo*-specific and κ-specific probes are shown underneath the respective genes, with the ^{32}P-labelled ends denoted by asterisks. Initiation sites and direction of SV40 early and κ transcription are shown by arrows, and translated regions of DNA are drawn in heavy line. L, leader segment; V, variable region; J, joining segment. The plasmid pLX40 and derivatives were constructed by standard methods; details are available on request to the authors. The *neo* and κ probes were prepared as described previously[2] with specific activities of $\sim 2 \times 10^6$ d.p.m. per pmol fragment.

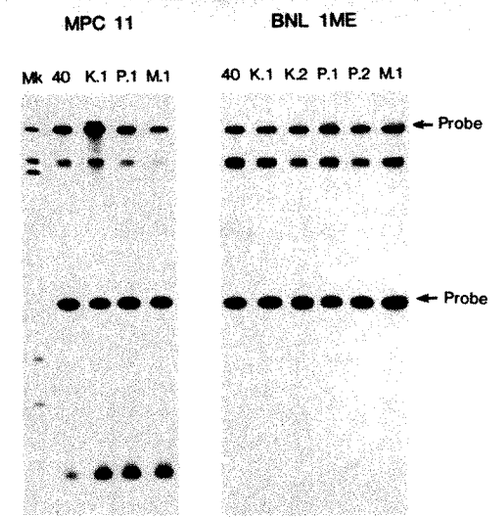

Fig. 2 S_1 nuclease assay of RNA from transfected cells. Cells of strains MPC 11 or BNL 1ME A.7R.1 were transfected with DNA of the indicated plasmids. Total RNA was extracted from the cells after 48 h and an equal aliquot of each RNA sample was hybridized at 53 °C to a *neo*-specific probe and at 48 °C to a κ-specific probe. After S_1 digestion, the reactions were combined and analysed on a polyacrylamide gel. The upper and lower bands marked probe co-migrated respectively with undigested *neo* and κ probe. The markers are from a labelled, denatured *Hin*fI digest of the plasmid pSV2-neo[12] and have lengths in nucleotides of 517, 396, 362, 134, 109 and 83. Mk, markers; 40, plasmid pLX40; K.1, pLX40K.1; K.2, pLX40K.2; P.1, pLX40P.1; P.2, pLX40P.2; M.1, pLX40M.1. Transfection of cells, extraction of RNA and S_1 assays were performed as described previously[2].

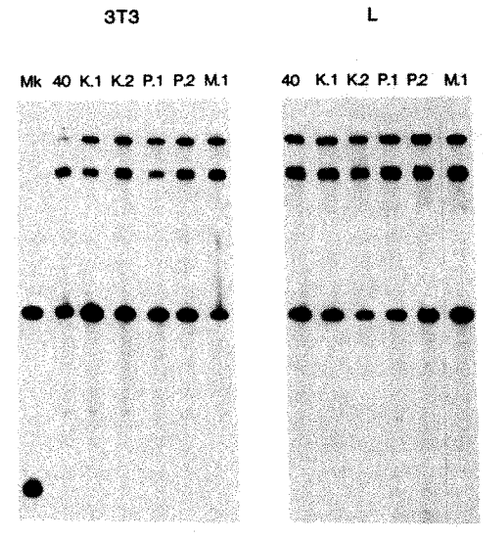

Fig. 3 S_1 nuclease assay of RNA from transfected cells. The assay was performed as in Fig. 2. Lane Mk is an S_1 analysis with the κ probe of RNA from MPC 11 cells transfected with pLX40P.1, performed in parallel with the other reactions. The cells were transfected as before[2], with the addition of a dimethyl sulphoxide shock step as described elsewhere[26].

initiating from the SV40 promoter; the band runs as a doublet because of heterogeneity in the SV40 early transcription start site[22]. Another strongly protected fragment was present in all the samples below the κ probe. This fragment is characteristic of transcripts initiated by the κ-chain promoter 25 bp before the first codon of the gene[4,7]. Neither the *neo*-specific nor κ-specific fragment were protected by RNA extracted from untransfected cells[2]. The transcription from the κ-chain promoter on pLX40 presumably resulted from the effect of the SV40 enhancer. κ-chain transcription was stimulated ~fivefold more by any of the murine enhancers (Fig. 2).

The set of plasmids was also transfected into a transformed line of liver cells BNL 1ME A.7R.1 (ATTC TIB 75) as a representative non-lymphoid cell line. Strong *neo*-specific bands were detected after S_1 analysis, showing that the plasmids were successfully transfected into the liver cells and could be transcribed. Indeed, more *neo* RNA was produced in the liver cells than in the myeloma cells, probably because of a higher transfection efficiency. Nonetheless, κ-chain transcripts were almost undetectable in the liver cell RNAs, although longer photographic exposures did reveal a small amount of κ-chain specific transcript from pLX40P.1, P.2 and M.1. Very similar results were obtained when the plasmids were transfected into mouse L and 3T3 cells (Fig. 3): the SV40 promoter transcribed the *neo* gene strongly on all the plasmids, but κ-chain transcription was very weak from pLX40P.1, P.2 and M.1 and undetectable from the other plasmids. The MSV enhancer is known to function in both L and 3T3 cells[16,18] and the polyoma enhancer functions in a wide range of cells, including 3T6 cells[19], and apparently in 3T3 cells where polyomavirus can replicate[14]. Hence, the very low level of κ-chain transcripts detected from pLX40P.1, P.2 and M.1 suggests that it is the κ-chain promoter itself which is intrinsically inactive in the non-lymphoid cells.

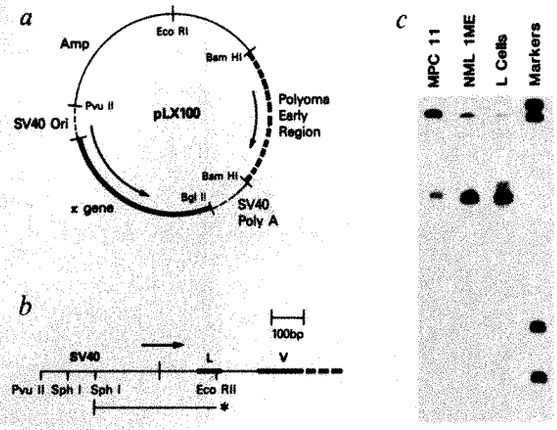

Fig. 4 *a*, Schematic diagram of the plasmid pLX100. Transcripts and sources of the DNA fragments are indicated as in Fig. 1. To construct the plasmid, a fragment of the plasmid pLX40 extending from the *Pvu*II site upstream of the κ gene (Fig. 1*b*) to the *Bam*HI site after the gene was inserted between the unique *Hin*dIII and *Bam*HI sites of the plasmid pSV2-neo[12]; the *Bam*HI polyoma fragment of pLX40 was then inserted at the *Bam*HI site of the new plasmid. *b*, Probe used for S_1 nuclease assays of RNA from pLX100. The probe is shown beneath the region of pLX100 where the SV40 origin and the κ gene are joined, with the ^{32}P-labelled end denoted by an asterisk. The arrow indicates transcription from the SV40 early promoter. *c*, S_1 nuclease assay of RNA from transfected cells. Cells of the indicated strains were transfected with pLX100 DNA, and extracted RNA was analysed at 53 °C with the probe shown in *b*. The topmost band in each lane co-migrated with undigested probe. The markers are part of a *Hin*fI digest of pSV2-neo DNA and have sizes in nucleotides of 396, 362, 134 and 109.

However, an alternative explanation is that κ-chain transcripts are synthesized at a higher level but are unstable in non-lymphoid cells. To eliminate this possibility, we constructed the plasmid pLX100 (Fig. 4*a*) in which the SV40 early promoter was attached to the same deleted κ-chain gene used in the pLX40 plasmids. The new plasmid was transfected into MPC 11, BNL 1ME and L cells, and extracted RNA was assayed by the S_1 method, using a suitable probe (Fig. 4*b*). In contrast to transcripts of the κ-chain gene initiating from its own promoter on the pLX40 plasmids (Figs 2, 3), transcripts of the κ-chain gene initiating from the SV40 promoter gave a strong signal (Fig. 4*c*). In fact, these transcripts were detected at a higher level in the non-lymphoid cells than in the myeloma cells, probably because of the higher transfection efficiency of the non-lymphoid cells seen above. In any case, the results show clearly that transcripts of this κ-chain gene are stable in non-lymphoid cells, and we therefore conclude that the κ-chain promoter initiates transcription very weakly in those cells.

We also transfected the pLX40 plasmids into lines of pre-B, B and T cells. We found that both the promoter and enhancer function in these cells, but not as efficiently as in myeloma cells, the activities in T cells being especially weak (manuscript in preparation).

The precise sequences responsible for the observed cell-type specificity of the κ-chain promoter may *a priori* be at a considerable distance from the actual transcription start site. However, we have shown that sequences more than 100 bp upstream of the start site are not required for high-level transcription in myeloma cells (C. Stauber and C.Q., unpublished data), and sequences downstream of the variable segment are also not required[7]. Hence, it seems likely that the actual sequences inducing high-level transcription specifically in B-lymphoid cells are fairly close to the transcription start site. Excellent candidates for these sequences would be two short regions of homology found in all light-chain genes examined, about 50–100 bp upstream of the start site[23,24]. Similar conclusions have recently been reached by others[25].

Identical V_β T-cell receptor genes used in alloreactive cytotoxic and antigen plus I–A specific helper T cells

Fabio Rupp, Hans Acha-Orbea, Hans Hengartner, Rolf Zinkernagel & Rolf Joho

Abteilung für Experimentelle Pathologie, Universitätsspital, Sternwartstrasse 2, 8091 Zürich, Switzerland

T lymphocytes involved in the cellular immune response carry cell-surface receptors responsible for antigen and self recognition. This T-cell receptor molecule is a heterodimeric protein consisting of disulphide-linked α- and β-chains with variable (V) and constant (C) regions[1–5]. Several complementary DNA and genomic DNA clones have been isolated and characterized[6–12]. These analyses showed that the genomic arrangement and rearrangement of T-cell receptor genes using V_T, diversity (D_T), joining (J_T) and C_T gene segments is very similar to the structure of the known immunoglobulin genes (see ref. 13 for review). We have isolated two cDNA clones from an allospecific cytotoxic T cell, one of which shows a productive V_β–J_β–C_β1 rearrangement without an intervening D_β segment. This V_β gene segment is identical to the V_β gene expressed in a helper T-cell clone specific for chicken red blood cells and H-2I^b (ref. 14). The other clone carries the C_β2 gene of the T-cell receptor, but the C_β2 sequence is preceded by a DNA sequence that does not show any similarity to V_β or J_β sequences.

An allospecific cytotoxic T-cell clone 3F9 of BALB/c origin with specificity for H-2D^b has been established[15]. To isolate cDNA clones bearing sequences for the different chains (α and β) of the T-cell receptor molecule(s), we constructed a cDNA library in the bacteriophage λgt11. A synthetic oligonucleotide complementary to part of the C region of the β-chain was synthesized and used to screen the λgt11-3F9 cDNA library for cross-hybridizing cDNA clones. Twenty such clones were isolated from ~100,000 recombinant phages. Southern blot analysis of cloned phage DNA indicated two groups of cDNA clones, probably corresponding to C_β1 and C_β2 sequences. One clone bearing the longest DNA insert of each group was chosen, and the cDNA was subcloned into the *Eco*RI site of pEMBL8 (−). The restriction map and sequencing strategy of the two clones is outlined in Fig. 1. Sequence analysis of p3F9-β1 confirmed that this clone was derived from a C_β1-bearing transcript

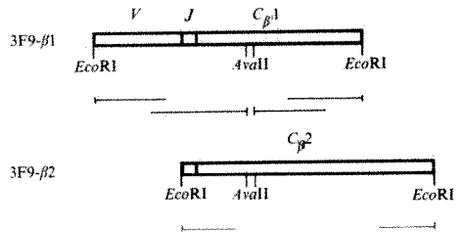

Fig. 1 Restriction site map and sequencing strategy. The 3F9 cDNA library and the cDNA clones p3F9-β1 and p3F9-β2 were produced according to standard procedures[18]. Briefly, poly(A) RNA was isolated from 3F9 cells and reverse transcribed into cDNA. Double-stranded cDNA was generated with reverse transcriptase and *Escherichia coli* polymerase I by self priming of second-strand synthesis. The DNA was methylated with *Eco*RI methylase, treated with S_1 nuclease, ligated to *Eco*RI linkers, size selected and cloned into λgt11 (ref. 19). An oligonucleotide complementary to the C region of the β-chain (position 211–239) was synthesized using an Applied Biosystem 380A DNA synthesizer, ^{32}P-labelled with [γ-^{32}P]ATP and T_4 polynucleotide kinase and used to screen the 3F9 cDNA library for cross-hybridizing phage clones. The cDNA inserts were subcloned into the *Eco*RI site of pEMBL8 (−) (ref. 20) and subjected to DNA sequence analysis [21].

(sequence not shown), whereas p3F9-β2 was derived from a $C_\beta 2$-bearing transcript (Fig. 3*b*).

Figure 2 shows the DNA sequence of the 5′ half of p3F9-β1. We found a DNA sequence encoding the $J_\beta 1.1$ gene segment upstream of the $C_\beta 1$ sequence. This $J_\beta 1.1$ sequence is preceded by a DNA sequence with an open reading frame. With two exceptions this sequence is identical to the known V_β gene segment of the T-helper cell line LB2, specific for chicken red blood cells and H-2I^b restricted[14]. The p3F9-β1 clone does not contain the 5′ end of the corresponding messenger RNA because its sequence lacks the first seven amino acids of the mature β-chain and the hydrophobic leader sequence when compared with the LB2 cDNA sequence. Towards the 3′ end of the V_β region, the p3F9-β1 sequence shows two base differences from the LB2 sequence. Both of these nucleotide changes alter the corresponding amino acids (Ala to Thr, and Leu to Ile); it is possible that these are either allelic differences between 3F9 (BALB/c) and LB2 (C57BL/6) or somatic mutations that have arisen during T-cell development. The V_β gene in LB2 is expressed with $J_\beta 2.3$ and $C_\beta 2$ and it is likely that a *D* gene segment has been inserted between V_β and $J_\beta 2.3$. A DNA sequence corresponding to the *D* gene segment of LB2 is missing in p3F9-β1. This implies that the V_β gene in 3F9 has joined directly to the $J_\beta 1.1$ gene segment or that the D_β gene segment has been deleted during a V_β to D_β-J_β joining event.

To confirm the absence of a *D* gene segment in 3F9, we determined the 3′ end of the V_β gene by comparing it with a germline V_β gene. A genomic unrearranged V_β gene had previously been cloned from B10.A liver DNA[8]. This germline V_β gene is homologous at its 3′ end with the V_β gene found in 3F9 and LB2 (Fig. 2). The last 17 nucleotides of the 2B4.71 germline *V*-region gene are identical to the sequence immediately preceding the $J_\beta 1.1$ gene segment in p3F9-β1. The 2B4.71 coding sequence ends with CTG (coding for Leu) and is followed by the conserved heptamer CACAGCA thought to be involved in *V*-(*D*)-*J* joining.

Comparison of the 3′ end of the 2B4.71 germline gene with the cDNA sequence of p3F9-β1 and LB2 implies that the 3′ end of the V_β gene in p3F9-β1 is represented by the triplet CTA (coding for Leu) and in LB2 by the triplet ATA (coding for Ile). From this we conclude that the same V_β gene can be used by T cells with different antigen specificities and different effector functions. In the allospecific killer T cells 3F9, the V_β gene is rearranged and transcribed as a V_β-$J_\beta 1.1$-$C_\beta 1$ unit without a *D* gene segment between the V_β and $J_\beta 1.1$ gene segment. In the chicken red blood cell-specific T-helper cell LB2, the same V_β gene has been rearranged and is transcribed as a V_β-*D*-$J_\beta 2.3$-$C_\beta 2$ unit[14]. Together with an earlier report[16] of a human cDNA molecule lacking a *D* gene segment inserted between *V* and *J* gene segments, this confirms the notion that diversity of the β-chain of the T-cell receptor can be created by insertion of none, one or more *D* gene segment(s) between the V_β and a J_β gene segment of the $J_\beta 1$ or $J_\beta 2$ gene cluster.

Our work shows that cytotoxic and helper T cells draw V_β genes from the same gene pool, although cytotoxic T cells are restricted by class I antigens of the major histocompatibility complex (MHC), whereas helper T cells recognize MHC class II molecules. If the V_α gene pool is also shared between cytotoxic and helper T cells, it becomes difficult to explain strict MHC class I versus class II restricted recognition of antigen by the $\alpha\beta$ heterodimer alone. In this light it is interesting that a third T-cell-specific molecule (the γ-chain) has been identified[17]. This γ-chain is predominantly expressed in cytotoxic T cells and it is thought to be part of a second receptor in cytotoxic T lymphocytes involved in recognition of MHC class I molecules. Alternatively, the distinction between class I and class II molecules could be made by the α-chain of a single receptor. In this case, V_α gene of cytotoxic and helper T cells should be derived from two different V_α gene pools.

Figure 3 shows part of the DNA sequence of p3F9-β2. The sequence corresponding to the 3′ end of the cDNA molecule is identical to the 3′ untranslated sequence of the $C_\beta 2$ gene so far sequenced. The 5′ end of the molcule has an open reading frame of 42 nucleotides (as far as the cDNA molecule extends) which leads into the start of the $C_\beta 2$ gene. The nucleotide sequence upstream of the $C_\beta 2$ gene is not the same as one of the $J_\beta 2$ gene segments normally found in this position. However, it is almost the same as a sequence detected upstream of the $D_\beta 2.1$ gene segment (at the 5′ end of the $J_\beta 2$ gene cluster)[12].

Figure 3 shows the sequence comparison of the 5′ end of p3F9-β2 and the genomic DNA sequence found 50–90 nucleotides upstream of the $D_\beta 2.1$ gene segment. The end of this homologous stretch of DNA is characterized by a consensus sequence of a donor site for RNA splicing. The p3F9-β2 cDNA is derived from a mRNA that may have arisen by splicing a RNA transcript from this genomic DNA sequence directly to the $C_\beta 2$ coding sequence. This means that the normal donor sites for RNA splicing which are present at the 3′ ends of the various $J_\beta 2$ gene segments have been omitted. The reasons for this aberrant RNA splicing are not clear; however, Southern blot analysis of genomic 3F9 DNA indicates that DNA deletions have occurred near the $J_\beta 2$ region (M. Schilham, R. Lang and

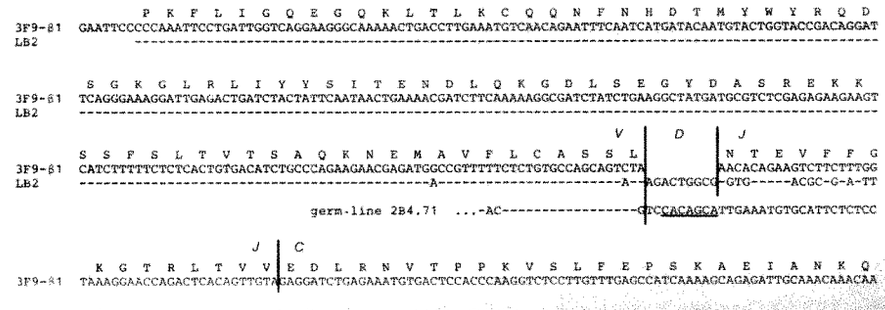

Fig. 2 Sequence of p3F9-β1. The V_β, $J_\beta 1.1$ and the beginning of the $C_\beta 1$ sequence of p3F9-β1 is shown and compared with the corresponding sequence of LB2 (ref. 14). The first seven nucleotides are derived from the *Eco*RI linker. Identical nucleotides are indicated by dashes. The germline (liver) gene 2B4.71 is shown to determine the *V*/*D* boundary of p3F9-β1 (ref. 8). The conserved heptamer following the coding region of the germline V_β gene is underlined.

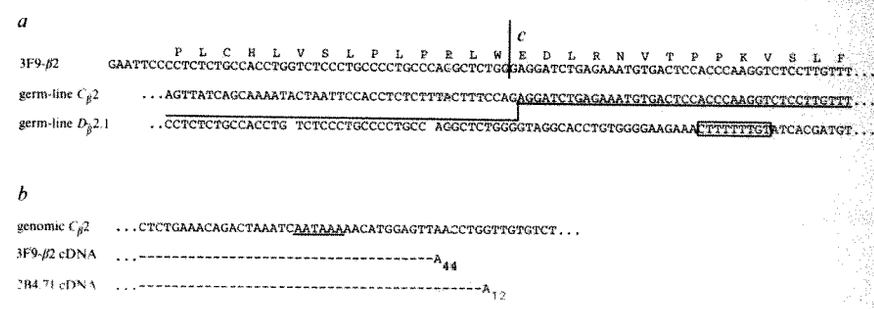

Fig. 3 Sequence of p3F9-β2. *a*, The 5′ terminal sequence and the beginning of the $C_\beta 2$ sequence are shown and compared with the germline sequence[10,11] of $C_\beta 2$ and a DNA sequence 5′ to the $D_\beta 2.1$ gene segment[12]. The conserved nonamer preceding the $D_\beta 2.1$ gene segment is boxed. The sequence found in the cDNA plasmid p3F9-β2 is indicated by a line. *b*, The 3′ terminal sequence of two cDNAs and the corresponding genomic sequence is shown. The polyadenylation signal ATAAA is underlined.

R.J., unpublished observations). Therefore, it is possible that the $J_\beta 2$ gene cluster has been deleted and a RNA transcript starting upstream of this deletion is now differently spliced. This finding implies that a promoter activity should be present 5′ of the J_β gene region. Similar cDNA molecules have been isolated from other T cells, but the cDNA molecules from other T cells contain J_β sequences 5′ of their respective C_β sequences[12,16].

p3F9-β2 contains a long tail of A residues at its 3′ end. Therefore, we could determine the position of poly(A) addition in the primary transcript. Figure 3*b* compares the 3′ ends of two different cDNA molecules both derived from a β2 mRNA with the corresponding genomic $C_\beta 2$ gene[10,11]. Although both transcripts are identical in the heteropolymeric region of the 3′ end, the site where polyadenylation begins varies by four to six nucleotides. If this does not result from allelic differences in the 3′ untranslated regions of 3F9 (BALB/c) and 2B4.71 (B10.A), then this comparison indicates that the exact position of polyadenylation is not determined on different transcripts even of the same gene.

Detection and sequence of mutations in the factor VIII gene of haemophiliacs

Jane Gitschier, William I. Wood, Edward G. D. Tuddenham*, Marc A. Shuman†, Therese M. Goralka, Ellson Y. Chen & Richard M. Lawn

Genentech, Inc., 460 Point San Bruno Boulevard, South San Francisco, California 94080, USA
* Haemophilia Centre, Academic Department of Haematology, Royal Free Hospital School of Medicine, London NW3 2QG, UK
† Hematology Section, Cancer Research Institute, University of California, San Francisco, California 94143, USA

The most common inherited bleeding disorder in man, haemophilia A, is caused by defect in factor VIII, a component in the blood coagulation pathway. The X-chromosome-linked disease almost certainly stems from a heterogeneous collection of genetic lesions. Because, without proper treatment, haemophilia can be a fatal disease, new mutations are necessary to account for its constant frequency in the population[1]. In addition, haemophilia A displays a wide range of severity, and some 15% of haemophiliacs generate high levels of antibodies against factor VIII ('inhibitor patients'). The present work elucidates the molecular genetic basis of haemophilia in some individuals. Using the recently cloned factor VIII gene as a probe[2,3], we have identified two different nonsense point mutations in the factor VIII gene of haemophiliacs, as well as two different partial deletions of the gene. Our survey of 92 haemophiliacs indicates no firm correlation between antibody (inhibitor) production and gross gene defects.

In an initial study involving 36 haemophilia patients, DNA samples were digested and analysed by Southern blot hybridization to the cloned factor VIII gene. Each DNA sample was digested with 4–11 restriction enzymes to search for variant hybridization patterns. One result of this endeavour has been the discovery of a common restriction fragment length polymorphism with *Bcl*I which allows the tracking of specific X chromosomes in many families. The use of this factor VIII DNA polymorphism in gene localization and prenatal diagnosis is reported elsewhere[4]. The restriction enzyme *Taq*I proved particularly useful for revealing differences in the DNA of individual haemophiliacs. This result is not surprising, because the recognition sequence for *Taq*I contains the CpG dimer, which is the major site of methylation of human DNA. CpG dimers are probably mutation hot spots because of subsequent deamination of methylcytosine to thymidine, resulting in C to T transitions[5]. The location of the affected restriction enzyme sites and the sequence of the factor VIII gene[2] alerted us to the possibility of in-frame stop codon mutations generated by C to T transitions in the *Taq*I sequence. Five of the seven *Taq*I sites in exons of the factor VIII gene can be converted to nonsense mutations by such a mechanism. We therefore concentrated on the screening of 92 haemophilic DNA samples with *Taq*I. (The restriction enzyme *Msp*I also contains CpG in its recognition sequence, but no variant hybridizing bands were found in 20 samples.) Case-specific *Taq*I site mutations were discovered in the DNA of four severe haemophiliacs (none of these four patients has any detectable factor VIII activity).

Figure 1 shows a representative Southern blot of 11 DNA samples digested with *Taq*I and probed with the 9-kilobase (kb) cloned factor VIII complementary DNA. Distinct variant fragments can be seen in haemophilic patients H2 and H6. The *Taq*I site change in patient H2 was mapped to exon 24 of the 26 exons comprising the human factor VIII gene[3]. A hybridiz-

ation probe containing only exons 21–26 simplifies the band pattern and was subsequently used in the analysis of DNA from haemophiliac H2 and members of his family (Fig. 2*a*). Absence of the *Taq*I site in exon 24 produces a 4.2-kb hybridizing band found only in patient H2. His mother as well as his father, sister and two brothers display the normal 1.4- and 2.8-kb fragments, but not the 4.2-kb fragment, suggesting that this new mutation occurred in the X chromosome of individual H2, a result consistent with the lack of previous haemophilia in this family.

A region of H2 DNA which includes this mutation was cloned into bacteriophage λ, and exon 24 was sequenced. The DNA sequence was identical to that of normal DNA analysed previously[2], except that the *Taq*I site had changed from TCGA to TTGA in the H2 DNA. This mutation generates an in-frame stop codon in the factor VIII gene 124 amino acids before the normal chain termination. Because this mutation was found in only 1 case out of 92 haemophilic and 80 non-haemophilic X chromosomes examined, and because it first appeared in the only affected member of this family, we propose that this nonsense mutation is likely to be the cause of haemophilia in this individual. In addition to having a new haemophilia mutation,

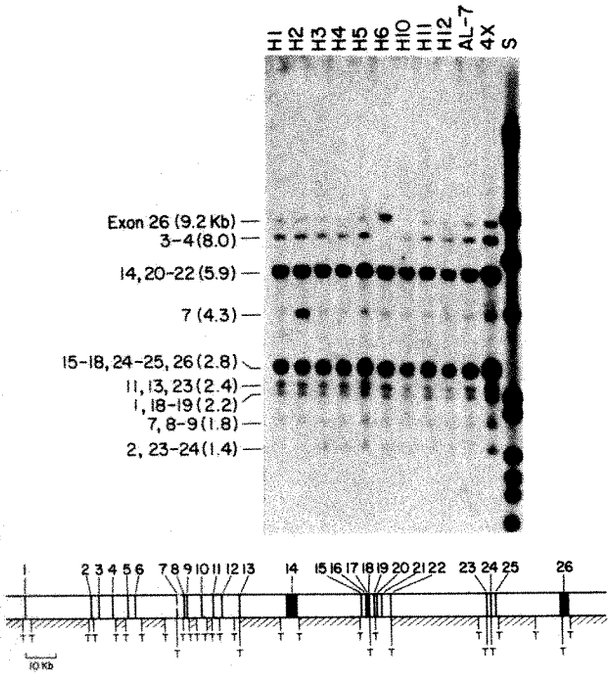

Fig. 1 Southern blot of haemophilia DNA samples showing two variations with the enzyme *Taq*I. The blot was hybridized to the full-length factor VIII probe (9.0-kb ClaI/*Sst*II fragment of pSAT.8cl; ref. 2) which contains all coding sequences and the 3′-untranslated region. Each hybridizing band corresponds to at least one exon; band sizes in kb are shown in parentheses. The lanes containing the haemophiliac samples are indicated by a number preceded by the letter H. The control lanes labelled AL-7 and 4X contain DNA prepared from cell lines which served as a source of the factor VIII mRNA and factor VIII genomic clones, respectively[2,3]. Lane S contains ^{32}P-end-labelled *Hin*dIII-digested λ DNA and *Hae*III-digested ΦX174 DNA as standards. The diagram shows the location of *Taq*I sites (T) in exons (indicated by a lower T) and introns of the factor VIII gene. The intron areas indicated by hatchmarks are not mapped with respect to *Taq*I sites as they are not detected by the factor VIII cDNA probe. Bands predicted to correspond to exons 5–6 and 12 were not detected in the blot shown; the size of the fragment corresponding to exon 10 is uncertain.

Methods. Genomic DNA (5 μg), prepared either from peripheral blood lymphocytes of haemophiliacs or from cell lines, was electrophoresed and blotted onto a nitrocellulose filter. The filter was hybridized to calf thymus primed ^{32}P-labelled probe in 50% formamide at 42 °C overnight and washed at 60 °C in 0.2XSSC before autoradiography[11,12].

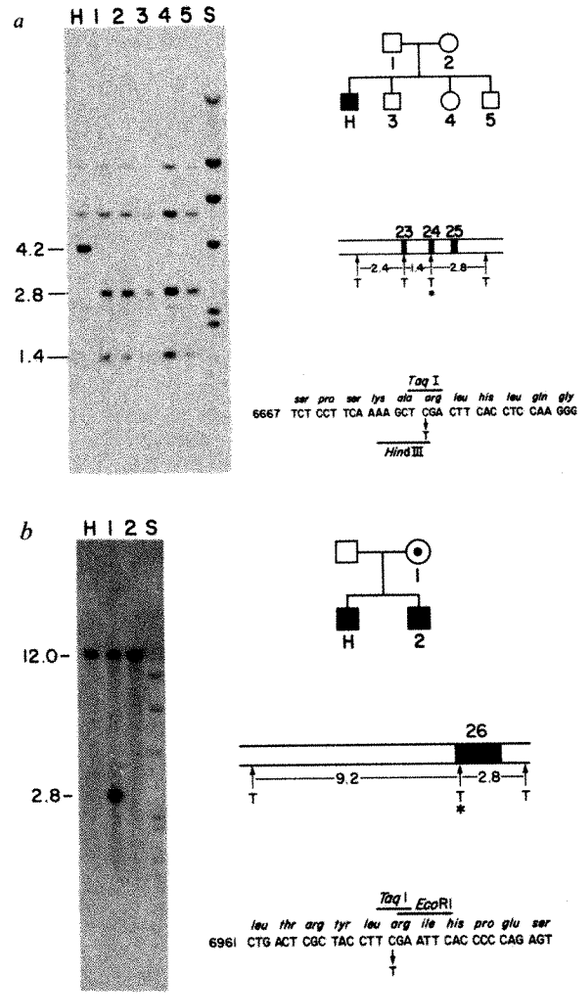

Fig. 2 Analysis of the factor VIII gene of patient H2 and patient H22. ***a***, A Southern blot of DNA from patient H2 and his family members was probed with a cDNA 783-bp *Apa*I/*Eco*RI fragment that includes all of exons 22–25 and parts of exons 21 and 26. Lanes H (haemophiliac), 1, 2, 3, 4 and 5 correspond to family members in the accompanying pedigree [□, normal male; ■, haemophiliac male; ○, normal female; ⊙, carrier female (not present on this particular pedigree)]. The diagram below the pedigree indicates with an asterisk the location of the missing *Taq*I site in exon 24. Below this is shown the sequence of normal DNA[2] and the changed base in H2 DNA that results in the loss of a *Taq*I site, the generation of a *Hin*dIII site (verified by a Southern blot, data not shown), and the occurrence of an in-frame stop codon TGA. The nucleotide number to the left follows ref. 2. ***b***, A Southern blot of *Taq*I-digested DNA from patient H22, his mother and brother was probed with a 1.9-kb *Eco*RI cDNA fragment (from clone λ10.3) that includes almost all of exon 26 (ref. 2). The mother (lane 1) has the normal 2.8-kb *Taq*I allele as well as the variant 12.0-kb allele, which she shares with her two haemophilic sons. The *Taq*I site that is missing in H22 DNA, and the normal DNA sequence and the altered nucleotide in H22 are indicated.

Methods. Blot hybridization was performed as described in Fig. 1 legend. For sequence analysis, DNA from patient H2 was preparatively digested with *Bam*HI. A 15-kb region, known to contain exon 24, was gel isolated and cloned into bacteriophage vector Charon 30 (ref. 11). An exon 24-containing 600-bp *Hae*III fragment of the resulting λ clone was subcloned into M13 and sequenced by dideoxy-chain termination procedures. The C to T transition is the only difference found between the normal and H2 sequence. Similarly, for patient H22, a 5.3-kb *Bam*HI fragment was cloned into vector Charon 30. A 1.6-kb *Sst*I/*Bam*HI fragment from this cloned DNA was then subcloned into M13 for sequencing from the *Sst*I site for ~600 bp to read through the *Taq*I and *Eco*RI sites.

H2 is also a significant case because the patient, a severe haemophiliac with <1% factor VIII activity, has developed an extremely high titre of anti-factor VIII antibody (8,000 Bethesda units).

A different premature termination mutation was found in patient H22. The *Taq*I site normally found in exon 26 has been lost, leading to the replacement of the normal 2.8-kb hybridizing band with a 12-kb band (Fig. 2*b*). Haemophiliac H22 and his haemophilic brother (Fig. 2*b*, lanes H and 2, respectively) display the 12-kb fragment, while DNA from their mother (lane 1), who is a carrier of haemophilia, contains the affected X chromosome with the 12-kb fragment, and a normal X chromosome with the 2.8-kb fragment. Cloning of H22 DNA and sequence analysis demonstrated a TCGA to TTGA transition of the *Taq*I site in exon 26, again generating an in-frame stop codon which we propose to be the basis of this haemophilia. Although this sequence predicts the synthesis of a protein only 26 amino acids shorter than normal factor VIII, such a truncated protein may well be inactive. The absent portion of the molecule is contained in one of the active subunits (relative molecular mass 80,000)[2,6,7] of the mature protein and includes a cysteine residue which is conserved in the duplicated C domains[3,7] and which may be important for the stability or active conformation of the protein. (Although patient H22 is a severe haemophiliac, he does not produce antibodies against factor VIII.)

In the case of patient H6, the missing *Taq*I site is located within an intron, about 400 base pairs (bp) 3′ to exon 2 and 2,000 bp 5′ to exon 3. Figure 3*a* illustrates the inheritance of this mutation in the H6 family. The normal *Taq*I fragments of 1.5 and 8.0 kb detected using a subgenic probe are replaced by a 9.5-kb fragment in H6 DNA. The haemophiliac's mother (Fig. 3*a*, lane 1) is an obligate carrier of haemophilia because her father (and four uncles) was a haemophiliac. The carrier status of the haemophiliac's sister and her two daughters (Fig. 3*a*, lanes 4–6) was unknown before this experiment. The results from this Southern blot indicate that the sister and one niece are carriers of haemophilia, whereas the other niece is not. We believe this to be the first carrier detection of haemophilia A made by DNA diagnosis using a probe within the factor VIII gene. The H6 DNA surrounding the missing *Taq*I site was cloned and sequenced and, again, a TCGA to TTGA transition in the *Taq*I site was found. This mutation does not create a sequence resembling consensus splice donor or acceptor sites[3,8], and is not located near the intron–exon borders. Thus, it is not apparent whether this sequence change leads to aberrant RNA splicing, and therefore whether it is directly responsible for the disease in this family.

The final variant involves a new *Taq*I site in haemophiliac H40 DNA. The site of mutation is in the last intron of the factor VIII gene, ~20 kb 3′ of exon 25 and 1.7 kb 5′ of exon 26. A TCAA to TCGA change creates the new *Taq*I site. Sequence analysis of this intron also revealed a second difference when compared with the sequence of our previously isolated genomic clones[3]. A T to C transition appears 22 nucleotides 5′ to the *Taq*I site mutation. We do not know whether this particular T-C variation is common among individuals. However, both of these sequence changes occur in a region homologous to the *Alu* family of interspersed repetitive DNA[9]. Furthermore, there is no obvious connection between these sequence anomalies in the H40 family and the disease; no consensus splice sites are created by these changes.

To summarize the *Taq*I survey, we have identified four independent *Taq*I site mutations in the factor VIII genes of haemophiliacs. Three of these involve the loss of a *Taq*I site (two of these changes are in exons) and one involves the introduction of a *Taq*I site in an intron. In addition to the 92 haemophilic DNA samples examined with *Taq*I, 80 normal (non-haemophilic) chromosomes have been screened by hybridization of Southern blots of *Taq*I-digested DNA with a full-length factor VIII probe. Of those 172 chromosomes, only the 4 *Taq*I site mutations have been observed, suggesting that each one is a rare variant (≤0.6%).

We propose that the in-frame stop codons found in exon 24 of the factor VIII gene in patient H2 and in exon 26 in H22 are the cause of haemophilia A in these families. Additional mutations cannot be ruled out, however. The phenotype could be due to inactivity or instability of the truncated protein or an effect of premature termination on the stability of the messenger

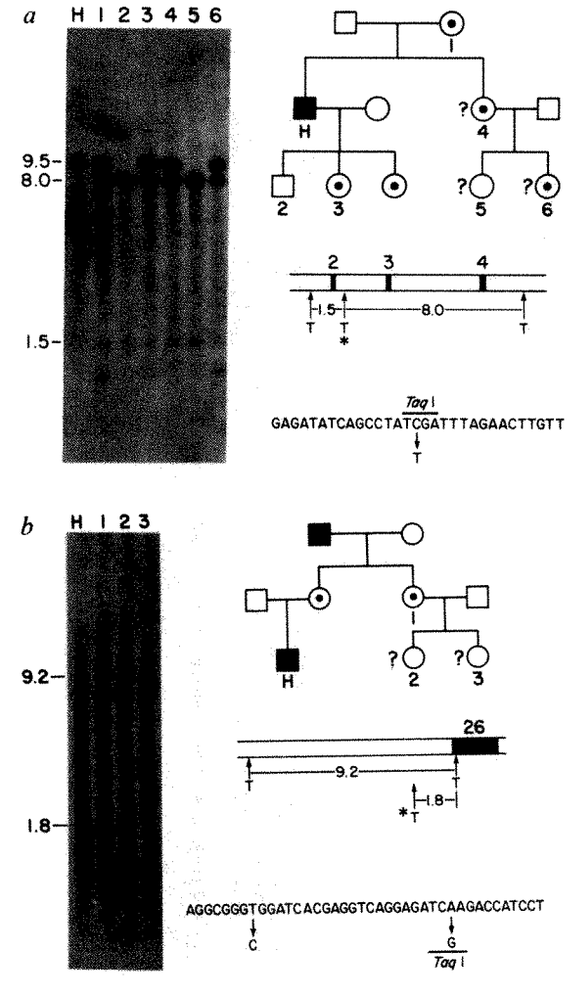

Fig. 3 Analysis of the factor VIII gene of patients H6 DNA and H40. ***a***, A Southern blot of *Taq*I-digested DNAs from patient H6 (H) and his family members was probed with 347-bp *Eco*RI cDNA fragment that includes only exons 2, 3 and 4 (ref. 2). The question marks on the pedigree indicate that before this experiment the carrier status of 4, 5 and 6 was unknown. The diagram below the pedigree shows the location of the *Taq*I site (T*) 3′ of exon 2 that is absent in the DNA of patient H6. Also shown is the sequence of normal DNA and the C to T change in the sequenced H6 DNA. ***b***, A Southern blot of *Taq*I-digested DNA from patient H40, his aunt and two cousins was hybridized to a ^{32}P-labelled 500-bp *Sst*I/*Eco*RI genomic fragment prepared from cosmid clone p613 (ref. 3). The unusual *Taq*I site in H40 DNA was mapped to an intron 1.7 kb 5′ of exon 26, as shown by T* in the schematic diagram. The 1.8-kb *Taq*I fragment is present in DNA samples from the haemophiliac and the aunt, who also has one normal allele, but is not found in DNA from the female cousins.

Methods. From the H6 DNA, the appropriate 7.0-kb *Bcl*I fragment was prepared and cloned into *Bam*HI arms of the Charon 30 vector. A 600-bp *Eco*RI/*Kpn*I fragment from this H6 λ clone, as well as the corresponding normal fragment from cosmid clone p624 (ref. 3), were subcloned into M13 and sequenced by dideoxy-chain termination methods. The C to T change in the *Taq*I site was the only difference in sequence between these two samples. From patient H40, *Bam*HI-digested DNA was preparatively run on a gel, and a 5.3-kb region, known to contain the new *Taq*I site, was isolated and cloned into Charon 30 vector. From this λ clone, a 1.0-kb *Sst*I/*Sma*I fragment was isolated, and along with the analogous normal fragment, a 1.0-kb *Sst*I/*Sma*I fragment from cosmid clone p613 (ref. 3), was cloned into M13 and sequenced.

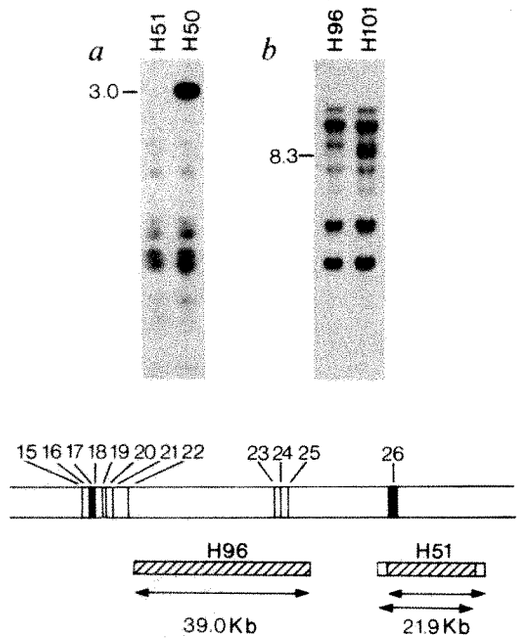

Fig. 4 Map of the deletions in the factor VIII genes of patients H51 and H96. ***a***, A Southern blot of *Rsa*I-digested genomic DNA from a number of haemophiliacs, including H51, was hybridized with the full-length factor VIII probe. A 3.0-kb *Rsa*I fragment present in all other haemophilic samples tested is absent in H51 DNA (only one non-deletion DNA, H50, is shown). To map the H51 deletion, three single-copy genomic fragments were prepared from a cosmid clone p625, which extends 37 kb beyond the 3′ end of the factor VIII gene. In addition, two genomic fragments 5′ of exon 26 were used. The extent of the 21.9-kb deletion in H51 DNA is shown below the diagram of the 3′ portion of the factor VIII gene. Due to the presence of repetitive DNA near the deletion boundaries, there is an uncertainty of ~2 kb in the precise deletion end points. ***b***, A Southern blot of *Sst*I-digested haemophilic DNAs similarly revealed that H96 DNA lacks an 8.3-kb fragment that is present in every other sample tested. The 39.0-kb deletion in H96 was mapped using one cDNA and three cloned genomic fragments from λ114, λ482 and p542 (refs 2, 3).

RNA. Neither patient H2 or H22 possesses detectable levels of factor VIII activity. (It has not been possible to measure truncated protein immunologically, as patient H2 produces high levels of anti-factor VIII antibodies, and patient H22 receives frequent infusions of factor VIII for treatment.) Eventual expression of these mutant genes in a heterologous cell system[2] may resolve these questions.

Finally, two cases of partial deletions of the factor VIII gene were detected in our survey. A Southern blot (Fig. 4) demonstrates that the DNA of patient H51 (a severe haemophiliac but not an inhibitor patient) lacks a 3.0-kb *Rsa*I fragment, which contains exon 26. Similarly, a Southern blot of *Sst*I-digested haemophiliac DNAs indicates that the DNA from the severe haemophiliac H96, who produces antibodies (10–50 Bethesda units), lacks an 8.3-kb fragment that includes exons 23–25. The extents of the H51 and H96 deletions were mapped by hybridizing genomic Southern blots with a series of cloned genomic probe fragments at the 3′ end of the factor VIII gene. In H96 DNA, the section missing from the factor VIII gene extends from 1 kb 3′ of exon 22 to 17.5 kb 5′ of exon 26, a total deletion of 39.0 kb. The deletion in H51 DNA, totalling 21.9 kb, extends roughly from 1 kb 5′ of exon 26 to 19 kb 3′ of the end of the transcribed factor VIII gene.

The 92 haemophilia A patients in this study can be categorized on the basis of their factor VIII activity as follows: 73 severe (<1% activity), 7 moderate (1–5% activity) and 12 mild (>5% activity). Fourteen of the severe haemophiliacs also produce inhibiting anti-factor VIII antibodies. All of the 92 DNA samples have been analysed with at least 2 restriction enzymes, while all 14 inhibitor patients were extensively examined with at least 6 enzymes to ensure resolution of all 26 exons of the factor VIII gene. In contrast to the findings of Giannelli *et al.*[10], who reported deletions in the factor IX gene of four out of five haemophilia B inhibitor patients, we observed only one case of a deletion (H96) in the factor VIII genes of the 14 haemophilia A inhibitor patients tested. The only other patient with a deletion found in this survey, H51, does not produce antibodies. Therefore, the suggestion that there is a correlation between the presence of antibodies and a deletion of part of the gene[10] is not borne out in the case of factor VIII.

We thank Yu-Cheng Liao and Doug Smith for assistance with DNA sequencing, Karen Wion and Philip Hollingshead for help with mapping, Jeanne Arch, Alane Gray and Carol Morita for manuscript preparation; Susan Karp, Laurie Weisberg and Peter Jones for collecting blood samples from haemophilia patients, Dennis Drayna for providing non-haemophiliac DNA samples, and the many patients and their families who participated in this study. This research was supported by Genentech, Inc.

A role for branchpoints in splicing *in vivo*

G. Rautmann & R. Breathnach

Laboratoire de Génétique Moléculaire des Eucaryotes du CNRS, Unité 184 de Biologie Moléculaire et de Génie Génétique de l'INSERM, Institut de Chimie Biologique, Faculté de Médicine, 11, rue Humann, 67085 Strasbourg Cedex, France

The nucleotides immediately surrounding intron/exon junctions of genes transcribed by RNA polymerase B can be derived from 'consensus' sequences for donor and acceptor splice sites by only a few base changes[1–3]. Studies *in vivo* have underlined the importance of these junction nucleotides for splicing[4–7]. In higher eukaryotes, no evidence has been found for specific internal intron sequences involved in splicing[8–10]. However, the recent discovery that, *in vitro*, introns are excised in a lariat form where the 5′ end of the intron is joined via a 2′-5′-phosphodiester linkage to an A residue (branchpoint acceptor) close to the 3′ end of the intron, suggests that internal intron sequences may nonetheless be important for splicing[11–13]. Indeed, in yeast nuclear genes, the internal sequence 5′-TACTAAC-3′ (or close homologue) is essential for splicing *in vivo*[14,15]. A proposed consensus sequence for branchpoints in mammalian introns is 5′-CT(A/G)A(C/T)-3′ (refs 11, 16, 17). This sequence resembles the essential yeast internal sequence. Are branchpoints involved in the splicing of introns of higher eukaryotes *in vivo*? We show here that a branchpoint sequence from a human globin gene (5′-CTGACTCTCTCTG-3′)[11] greatly enhances the efficiency of splicing of a 'synthetic' intron in HeLa cells. A mutated branchpoint sequence, 5′-CTCCTCTCTCTG-3′, in which the branchpoint acceptor nucleotide A has been deleted and the neighbouring purine G mutated to a C, does not exhibit this enhancing capability. We conclude that branchpoints have an important function in the splicing process *in vivo*.

We have described elsewhere the construction of synthetic splice sites designed to conform to the consensus sequences for

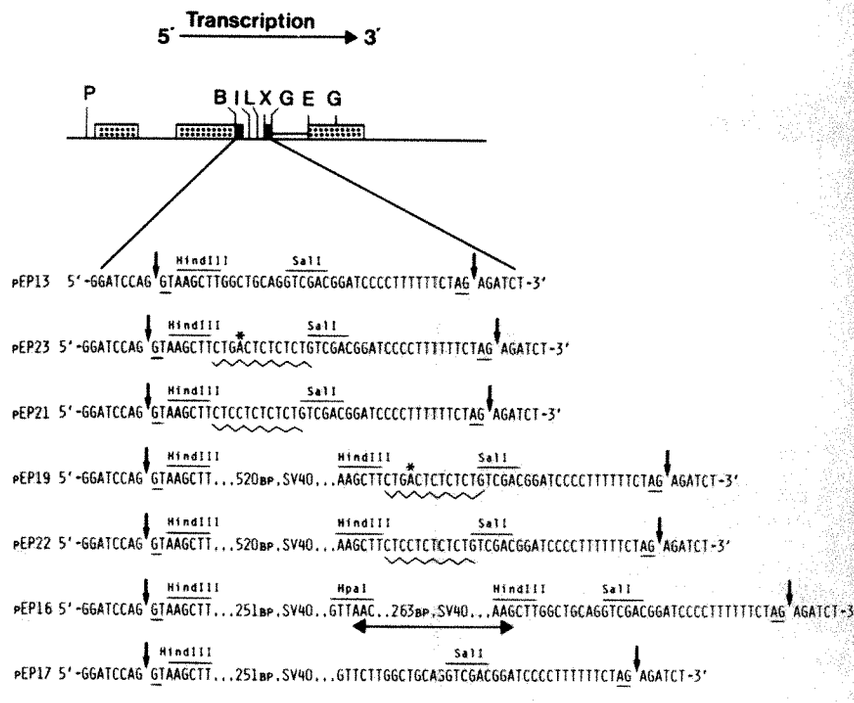

Fig. 1 Transcription units used to study splicing of synthetic introns. Dotted boxes represent rabbit β-globin gene exons and solid boxes represent exon sequences of the splicing oligonucleotide as described elsewhere[7]. Thus, the 5′ solid box represents the sequence 5′-GGATCCAG-3′ and the 3′ solid box the sequence 5′-AGATCT-3′. The *Bgl*II/*Eco*RI fragment shown as a double line represents a ~100-bp fragment of pBR328 (see ref. 7 for a full discussion). P, *Pst*I; B, *Bam*HI; I, *Hin*dIII; L, *Sal*I; X, *Xba*I; G, *Bgl*II; E, *Eco*RI. Sequences of synthetic introns described in the text are shown. Splice points are marked by arrows, and the invariant dinucleotides GT and AG present at the 5′ and 3′ ends of introns, respectively, are underlined. Construction of pEP13, pEP16 and pEP17 has been described elsewhere[7]. The *Hpa*I/*Alu*I fragment of the internal intron sequence of pEP16 deleted to make pEP17 is shown by horizontal arrows below the pEP16 sequence. *Hin*dIII and *Sal*I sites used to introduce the globin branchpoint sequence[11] 5′-CTGACTCTCTCTG-3′ or its mutated counterpart 5′-CTCCTCTCTCTG-3′ are shown (wavy underlining). The branchpoint acceptor nucleotide A used to make a 2′-5′-phosphodiester linkage with the G residue at the 5′ end of the intron is shown by an asterisk in the pEP23 and pEP19 sequences.

Methods. To introduce the branchpoint sequence, chemically synthesized[18] oligonucleotides 5′-AGCTTCTGACTCTCTCTG-3′ and 5′-TCGACAGAGAGAGTCAGA-3′ (phosphorylated at their 5′ ends by treatment with ATP and polynucleotide kinase) were mixed in a 1:1 ratio and ligated to a phosphatase-treated *Hin*dIII + *Sal*I digest of pEP13. pEP23 generated in this manner was linearized with *Hin*dIII and ligated to a *Hin*dIII fragment of SV40 DNA (bp 3,476–4,002, BBB numbering system[19] to make pEP19. The same *Hin*dIII fragment is present in the same orientation in pEP16, pEP 19 and pEP22. It has been represented in a different fashion in pEP16 only to show the deletion used to generate pEP17. A similar strategy was used to construct pEP21 and pEP22. Drawings are not to scale.

donor and acceptor splice sites and their expression *in vivo* as RNA from a β-globin gene vector[7]. This vector (pEP1, Fig. 2) contains a rabbit β-globin gene linked to simian virus (SV40) enhancer. In plasmids designed to express the synthetic splice sites, the *Bam*HI/*Eco*RI fragment of pEP1 carrying the globin large intron and flanking exon/intron junctions was replaced by a *Bam*HI/*Eco*RI fragment carrying the synthetic donor (5′-GGATCCAG↓GTAAGCTT-3′) and acceptor (5′-CTTTTTTCTAG↓AGATCT-3′) splice sites separated by various synthetic introns. In pEP13, the synthetic splice sites are separated by an internal intron sequence derived from the bacterial plasmid pUC8 (Fig. 1). In pEP16, a 526-base pair (bp) *Hin*dIII fragment from SV40 genomic DNA has been added to the internal intron sequences of pEP13 (Fig. 1). When introduced into HeLa cells by the calcium phosphate co-precipitation technique, both of these plasmid constructions lead to a very small amount of cytoplasmic RNA in which the synthetic donor splice site has been correctly spliced to the synthetic acceptor splice site[7].

Deletion of some internal intron sequences from pEP16 (arrows in Fig. 1) generated pEP17 (Fig. 1). Much greater amounts of correctly spliced RNA were obtained from cells transfected with pEP17 than with either pEP13 or pEP16 (see Fig. 10 of ref. 7 and below). It seemed possible that pEP13 and pEP16 lacked a sequence capable of functioning efficiently as a branchpoint. The deletion used to generate pEP17 might have fortuitously positioned a branchpoint sequence at a suitable distance from the synthetic acceptor, thereby greatly increasing splicing efficiency. A possible candidate for such a sequence is the pentanucleotide 5′-TTAAA-3′ positioned 50 nucleotides away from the acceptor splice site in pEP17 (within the 251-bp SV40 DNA segment (Fig. 1), but over 270 nucleotides away from the acceptor splice site in pEP16 (the sequences 5′-TTAAC-3′ and 5′-TTAAT-3′ have been proposed as branchpoints[16]). To test the hypothesis that pEP13 and pEP16 lack an efficient branchpoint sequence, we decided to introduce a known branchpoint sequence into these plasmids and test its effect on splicing.

The *Hin*dIII/*Sal*I fragments in the internal intron sequences of pEP13 and pEP16 were replaced by synthetic *Hin*dIII/*Sal*I fragments carrying the identified branchpoint sequence (5′-CTGACTCTCTCTG-3′) of a human globin gene[11] to generate pEP23 and pEP19, respectively (Fig. 1; pEP16 and pEP19 contain the same *Hin*dIII fragment in the same orientation). Each of these four plasmids and pEP17 was introduced by the calcium phosphate co-precipitation technique into HeLa cells, together with pEP1 (to monitor the efficiency of the transfection). Cytoplasmic RNA was collected 72 h later and used for S_1 nuclease mapping with a mixture of two 5′-end-labelled single-stranded DNA probes. One of these probes (probe A, Fig. 2) detects correctly spliced globin RNA derived from pEP1; this RNA will protect 54 nucleotides of probe A from S_1 nuclease digestion. The second probe (probe D, Fig. 2) is designed to detect RNA derived from pEP13, pEP16, pEP17, pEP19 or pEP23 in which both the small globin intron and the synthetic intron have been correctly removed by splicing. Such spliced RNA will protect 325 nucleotides of probe D from S_1 nuclease digestion (Fig. 2).

Figure 3 shows that much less spliced RNA is obtained with pEP13 and pEP16 than with pEP17, confirming our previous observations[7]. (We term spliced RNA, here and below, as RNA in which the synthetic donor site has been spliced to the synthetic acceptor site. We have shown previously[7] that when the synthetic acceptor is not used for splicing to the synthetic donor, splicing of the latter to a cryptic splice site in the *Eco*RI/*Bgl*II globin exon fragment occurs. This RNA cannot be detected using probe D.) Of the plasmids containing the globin branchpoint sequence, one (pEP23) yielded low levels of spliced RNA similar to those observed with pEP13 and pEP16, while the other (pEP19) yielded much higher levels of spliced RNA, similar to those observed with pEP17. It is highly unlikely that these results are due to different transfection efficiencies, as in all cases, roughly similar amounts of globin RNA were produced from the co-transfected pEP1 (as evidenced by the intensities of the ~54-nucleotide protected fragment in each lane of Fig. 3).

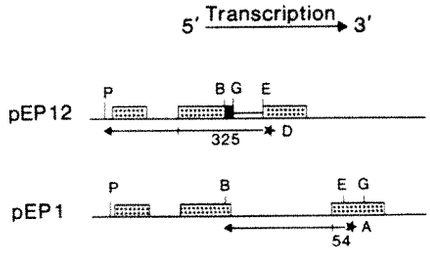

Fig. 2 Probes used for S_1 nuclease mapping. Symbols are as described in Fig. 1 legend. Construction of pEP1 and pEP12 has been described elswhere[7]. Briefly, pEP1 contains a rabbit β-globin gene linked to an SV40 enhancer. pEP12 represents a cDNA version of pEP13 from which the synthetic intron sequence has been deleted using the enzymes *Bam*HI and *Xba*I. For preparation of probe D, a *Pst*I/*Eco*RI fragment of pEP12 was 5′-end labelled with [γ-^{32}P]ATP and polynucleotide kinase, and strand-separated as described previously[7]. The strand labelled at the *Eco*RI terminus was isolated. RNA extracted from HeLa cells transfected with any of the plasmids pEP13–pEP23 in which both the small globin intron and the synthetic intron have been removed correctly will protect 325 nucleotides of probe D from nuclease S_1 digestion as shown (see ref. 7 for a more detailed discussion). For preparation of probe A, a *Bam*HI/*Eco*RI fragment of pEP1 was 5′-end-labelled and strand-separated. The strand labelled at the *Eco*RI terminus was isolated. Globin RNA from pEP1 will protect 54 nucleotides of this probe from nuclease S_1 digestion as shown. Drawings are not to scale. Cuts on the arrows indicate extents of probes protected by correctly spliced RNA.

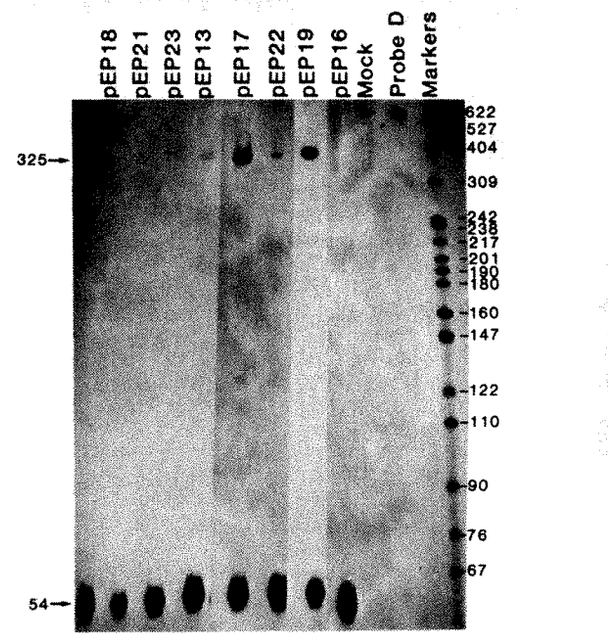

Fig. 3 Effect of a globin branchpoint sequence on splicing of synthetic introns. Plasmids shown in Fig. 1 were mixed in a 4:1 ratio with pEP1 and introduced into HeLa cells by the calcium phosphate co-precipitation procedure. Cytoplasmic RNA was isolated 72 h later and 50 μg used for nuclease S_1 mapping with a mixture of probes A and D (Fig. 2). Protected fragments of probe were electrophoresed on an 8% polyacrylamide 7 M urea gel. Size markers are from an *Msp*II digest of pBR322. Fragments of probe A protected by RNA from pEP1 are indicated by their size, ~54 nucleotides. Fragments of probe D protected by RNA from pEP13–pEP23 are also indicated by their size, ~325 nucleotides. Mock, mock-transfected HeLa cells. All experimental conditions were as described previously[7].

Introduction of a globin branchpoint sequence into the synthetic intron of pEP16 thus leads to a large increase in splicing efficiency. A similar effect is not seen for pEP23, perhaps because in this plasmid the branchpoint acceptor nucleotide A of the sequence 5′-CTGACTCTCTCTG-3′ is too close to the 5′ end of the intron (only 11 nucleotides away). However, there are clearly other differences between pEP19 and pEP23 (for instance intron size) which could explain the reduced splicing efficiency observed with the latter construction. We also show in Fig. 3 results obtained with pEP18, a version of pEP23 containing a branchpoint of the form 5′-CTGATCTCTCTG-3′ and thus carrying a single-nucleotide deletion relative to the pEP23 branchpoint. A low level of spliced RNA, similar to that seen with pEP23, was obtained with pEP18. If the significantly higher efficiency of splicing observed with pEP19 as compared with pEP16 is due to the presence of an efficient branchpoint sequence in the former, elimination of the branchpoint acceptor nucleotide A from the sequence 5′-CTGACTCTCTCTG-3′ present in pEP19 should greatly decrease splicing efficiency. The plasmid pEP22 contains the mutated branchpoint sequence 5′-CTCCTCTCTCTG-3′ (Fig. 1). For the mutated branchpoint sequence, we chose to delete the branchpoint acceptor nucleotide A and to mutate the neighbouring G residue to a C, as, although the branchpoint acceptor nucleotides identified to date are all A, it has not been demonstrated that a G cannot function as a branchpoint acceptor. We hypothesized that a pyrimidine would be less likely to function in this way, and therefore mutated the G to a C. Levels of spliced RNA obtained with pEP22 were indeed low (Fig. 3), and comparable to those obtained with pEP13. As expected, pEP21, a version of pEP23 with the mutated branchpoint sequence, also gave rise to the low level of spliced RNA apparently characteristic of constructions lacking an efficient branchpoint sequence.

We have shown that introduction of a globin branchpoint sequence into a synthetic intron can greatly enhance splicing efficiency, thus demonstrating the importance of branchpoint sequences for splicing *in vivo*. We assume that the low levels of spliced RNA obtained with constructions such as pEP13 and pEP16 reflect the use of an inefficient branchpoint, although it has not been shown that a branchpoint is essential for splicing. The sequence features defining a branchpoint and its optimal position relative to an acceptor splice site are unknown. Plasmids such as pEP16 which lack an efficient branchpoint sequence should prove useful in this respect.

We thank P. Chambon for useful discussions, M. C. Gesnel, M. Acker and B. Augsburger for technical assistance, A. Staub for synthesis of the oligonucleotides used in this work, and B. Boulay, C. Werlé and C. Aron for preparation of the manuscript. G.R. was a recipient of a grant from the Ligue Nationale Française contre le Cancer. This work was supported by grants from the CNRS, INSERM, the MIR (88V0092), the Fondation pour la Recherche Médicale and the Association pour le Développement de la Recherche sur le Cancer.

Two new volumes in the Topics in Molecular and Structural Biology Series

THE DEVELOPMENT AND EXPLOITATION OF BIRTHWEIGHT STANDARDS
by Roy Carr-Hill and Colin Pritchard

The result of a detailed study, this book suggests methodologies for constructing birthweight standards using a sample population. The results are of widespread clinical importance.

0 333 37297 2 208pp £40

CENTRAL AND PERIPHERAL MECHANISMS OF COLOUR VISION
edited by David Ottoson and S. Zeki

This book puts forward completely new interpretations and theories for the neurophysiological mechanisms of colour vision.

May 0 333 39321 X 350pp £40

THE DETECTION OF NEW ADVERSE DRUG REACTIONS
edited by M. D. B. Stephens

May 0 333 36886 X 240pp £25

DECISION MAKING IN GENERAL PRACTICE
edited by M. Sheldon, J. Brooke and A. Rector

July 0 333 36626 3 208pp £25

GENETIC TOXICOLOGY TESTING
edited by J. M. Parry and C. Arlett

Describes a collaborative study to investigate the mutagenic and carcinogenic properties of a series of "model" chemicals.

July 0 333 38897 6 350pp £40

THE MUSCLE SPINDLE
edited by I. A. Boyd and M. H. Gladden

New research reported in this book will be of great importance to neurophysiologists.

July 0 333 38446 6 £40

THE MANAGEMENT OF AIDS PATIENTS
edited by D. Miller, J. Weber and J. Green

Urgently required information by health professionals everywhere.

August 200pp hardback 0 333 40465 3 £25
paperback 0 333 40466 1 £9.95

QUANTITATIVE NEUROANATOMY IN TRANSMITTER RESEARCH
edited by Luigi Agnati and Kjell Fuxe

As well as recording the latest research findings this volume illustrates the use of new techniques in detecting and demonstrating the roles of different sections of the neuroanatomy in transmission.

September 0 333 39637 5 370pp £50

POLYSACCHARIDES
edited by E. D. T. Atkins and H. H. Wills

October 0 333 33371 3 250pp £30
Topics in Molecular and Structual Biology Series

MECHANISMS OF DRUG ACTION, VOLUME 1
edited by G. N. Woodruff

The first in a series of multi-contributed works looking in detail at the mechanisms by which various types of drugs affect functions of the body's systems.

November 0 333 39323 6 250pp £30

Four Satellite Symposia of the Ninth IUPHAR Congress, August 1984

FOLATES AND PTERINS, Volume 2: Chemistry and Biochemistry of Pterins

edited by **R.L. Blakley,** *St Jude Children's Research Hospital, Memphis, Tennessee* and **S.J. Benkovic,** *The Pennsylvania State University*

The first comprehensive review of folates in fifteen years. The contributions to the book, provide up-to-date accounts of folate metabolism and chemistry, explaining the metabolic basis for many forms of anemia and providing the basis for understanding the action of certain anticancer drugs, and detail the enzyme targets of some drugs used in treating cancer.

Series: Biochemistry: A Series of Monographs.

Contents: Naturally Occurring Pterin; Chemistry of Naturally Occurring Pterins; Biosynthesis of Pterins; Catabolism of Pterins; Phenylalanine Hydroxylase and Dihydropterin Reductase; Tyrosin Hydroxylase; Tryptophan Hydroxylase; Pterins in Other Metabolic Pathways; Index.

0471 89121 5 430pp April'85 £103.50

ALKALOIDS: CHEMICAL AND BIOLOGICAL PERSPECTIVES, Volumes 2 and 3

edited by **S.W. Pelletier,** *University of Georgia*

This interdisciplinary monograph series will provide up-to-date, comprehensive, and authoritative reviews on the chemistry and biological properties of the various classes of alkaloids. The scope of the series will include chapters on structure elucidation, chemical properties, synthesis, biogenesis, pharmacology, physiology, taxonomy, spectroscopy, and X-Ray Crystallography of Alkaloids.

Volume 2

Contents: Some Uses of X-Ray Diffraction in Alkaloid Chemistry; The Imidazole Alkaloids; Quinolizidine Alkaloids of the Leguminosae: Structural Types, Analyses, Chemotaxonomy, and Biological Properties; Chemistry and Pharmacology of the Maytansinoid Alkaloids; 13C and Proton NMR Shift Assignments and Physical Constants of C19-Diterpenoid Alkaloids; Subject and Organism Indexes.

0471 89299 8 504pp Dec'84 £69.35

Volume 3

Contents: The Pyridine and Piperidine Alkaloids: Chemistry and Pharmacology; The Idolosesquiterpine Alkaloids of the Annonaceae; Cyclopeptide Alkaloids; Cannabis Alkaloids; Synthesis of Lycopodium Alkaloids; The Synthesis of Indolizidine and Quinolizidine Alkaloids of *Tylophora, Cryptocarya, Ipomoea, Elaeocarpis* and Related Species; Recent Advances in the Total Synthesis of Pentacycic *Aspidosperma* Alkaloids; Indexes.

0471 89302 1 336pp March'85 £88.60

FUNGAL NUTRITION AND PHYSIOLOGY

by **M.O. Garraway,** *The Ohio State University,* and **R.C. Evans,** *Rutgers University*

A text for fungal physiology courses with a nutritional emphasis, discussing fungal nutrition and its implications for growth, development, and metabolite production. Main themes of the book are preceded by a review on structure of the fungal cell, followed by chapters on dormancy and germination, growth and reproduction, metabolism, and protein synthesis. The book is extensively illustrated, with tables and bibliography to amplify topics.

0471 05844 0 412pp Aug'84 £52.00

GROWTH AND MATURATION FACTORS, Volume 3

edited by **G. Guroff,** *National Institutes of Health, Bethesda, Maryland*

Critically examines specific growth factors, accounts for the effects of several factors on specific organs or organ systems, discusses methods applicable to all factors and covers growth factors from a more clinical aspect. The series touches upon just about every area of biological science, from neurobiology to oncology, basic research to clinical protocols.

Contents: Fibroblast Growth Factor; Ocular Growth and Differentiation Factors; Regulation of Neuronal Survival and Neuritic Growth in the Avian Ciliary Ganglion by Trophic Factors; Glia Maturation Factor and Other Factors Acting on Glia; Target Analysis of Growth Factor Receptors; Growth Factors in Fetal Development; The Mitogenic Effects of Proteases; Growth Factor Action and Ionic Signal Transduction: Characterization and Relation to Receptor Expression; Retinoids and Their Modulation of Cell Growth; B-Cell Growth Factors; Index.

0471 09707 1 344pp April'85 £86.15

MANUAL OF NONFERMENTING GRAM-NEGATIVE BACTERIA

by **T.R. Oberhofer,** *Madigan Army Medical Center*

This advanced laboratory manual is essential to the efficient recognition, identification and characterization of nonfermenting bacteria. The book provides detailed explanations of media selection and test performance as well as extensive tables of identification. Included are proven methods for identifying and differentiating clinical isolates.

0471 80544 0 168pp March'85 (pr) £29.00

MANUAL OF PRACTICAL MEDICAL MICROBIOLOGY AND PARASITOLOGY

edited by **T.R. Oberhofer,** *Madigan Army Medical Center, Tacoma, Washington*

A practical manual describing test procedures and methods used in clinical microbiology focusing on tests used for the recovery, isolation, and identification of aerobic bacteria, mycobacteria, and human parasites. It is intended as a working guide that will be of practical use in the performance of currently recognized and accepted conventional tests and newer, less widely known tests. Detailed procedures provide insight into the nature, purpose, and function of each test, and present areas of interest not readily found in most texts or references.

0471 80543 2 503pp March'85 (pr) £37.85

BIOLOGICAL REFERENCE MATERIALS: Availability, Uses, and Need for Validation of Nutrient Measurement

edited by **W.R. Wolf,** *United States Department of Agriculture*

This book deals with the development and distribution of certified biological reference materials and other homogeneous and well-characterized biological materials useful in the improvement of analytical methods for nutrient analysis. This book documents the availability of these materials for improving specific procedures and methodologies in this measurement system.

Contents: Certified Materials Available or in Preparation; Homogeneous and Well-Characterized Materials; Quality Control Materials for Nutrient Analysis; Environmental Specimen Banking; Open Discussion; Appendix; Index.

1687 and all that

A. Rupert Hall

Revolution in Science. By I. Bernard Cohen.
Harvard University Press: 1985. Pp.656. $25, £22.75.

FOR a considerable period of time historians and philosophers, but not to any extent working scientists, have debated the question: has the development of modern science been steadily continuous, or has it occurred by leaps and bounds with essentially level passages in between? The anonymous features that can be counted — numbers of scientists or journals, expenditure on research — show a reasonably smooth (and mutually comparable) exponential increase; but at the other extreme, selecting individuals, there is a universal belief that some have achieved far more than others. We speak of bosons and fermions, of amps and volts, of Newtonian mechanics and Mendelian genetics, and so in the ordinary discourse of science honour one name in a generation while forgetting all the others. Few doubt that despite the regularity of statistics the scientific papers of a Freud or an Einstein have meant more than the publications of many competent professional scientists. Moreover, the sense of singularity attaches to movements and institutions as well as to individuals: to the group of theoretical astronomers beginning with Copernicus and ending with Newton; to the Cavendish laboratory in the early part of this century; to the group of French chemists headed by Lavoisier who produced the *Méthode de Nomenclature Chymique* of 1787. There are networks of people who have collectively, so to speak, brought a given piece of science to the boil, and institutions that have maintained ebullition for a generation.

Astronomy as metaphor — political structures represented as a cosmos in the "Astronomical System of the French Revolution" (c. 1790). Nation, law and king replace the Sun at the centre of the system. (Reproduced from Revolution in Science.*)*

Boiling is clearly a different phenomenon from the slow and steady rise of temperature preceding it. Twenty odd years ago Thomas S. Kuhn generalized an alternation of steady and revolutionary states in the history of the different branches of science into a normal, indeed perpetual feature of science, at least for the "modern" epoch. Now his neighbour in Cambridge, Massachusetts, I. Bernard Cohen, has perfected a spacious study of the whole idea of revolution. Revolutions of the hours, of the planets, of states, of politics, of philosophy, are all gathered into his net but not (perhaps because the vehicles of expression are different) revolutions in painting and music. A whole chapter is given to the German equivalents of the romance noun "revolution" and another to the common (though erroneous) dictum that Immanuel Kant qualified his revolution in metaphysics as "Copernican" (Kant incidentally used the word "revolution" on 57 occasions and a German synonym such as "Umlauf" on 108!). The history of the phrase "industrial revolution" and its appropriateness in historiography are discussed in one chapter, the question of whether Alfred Wegener effected a revolution in the earth sciences in another. It is clear, even from these few examples, that the various chapters of the book are not on all fours with one another: some seem to be much concerned with *language* (as employed in exposition or apologia, in history or in philosophy), others with *judgement* (contemporary or later) of the significance of particular ideas or investigations.

It is hardly surprising that some great scientists (Einstein is a prominent example) have preferred the evolutionary to the revolutionary view of scientific progress, as Newton did too in his phrase about standing on the shoulders of giants, or that the idea of successions of revolutions in the sciences has commended itself more to historians, philosophers, sociologists and journalists than to the more modest of the innovators themselves. Again, Cohen documents learnedly the truth of the fairly obvious expectation that *talk* of revolutions in science has tended to become more usual as the *fact* of political revolution has become more common and traces the increasing frequency of political metaphor in the discourse of science itself. (The vivid case of the great cell pathologist and political activist Rudolf Virchow has been recently analysed by Renato Mazzolini.) Any suggestion, however, of a direct connection between sociopolitical revolution and revolution in science (considering, for example, the simultaneity of the special theory of relativity with the abortive Russian revolution in 1905) is surely to be regarded with scepticism: the Soviet Union, no mean exporter of political revolution, has tended towards conservatism in the wider issues of science, following the lead of Lenin.

Bernard Cohen's monumental scholarship makes evident in overwhelming detail the currency, since the late seventeenth century, of the notion that certain discoveries or theories have "revolutionized" science. His choice of examples is wide both in time and in topic: in sheer variety of riches this book has few parallels. From John Freind's affirming Harveian influence upon the treatment of amputations to the astronomical system of the French Revolution, it embraces a wealth of intriguing curiosities. Broadly, however, biology suffers in comparison with the physical sciences: the names of Schleiden and Schwann occur only in a quotation from Friedrich Engels. The late-nineteenth and twentieth century revolution in the medical sciences is silently passed over.

Not that one needs more examples, for it might be said that Cohen has both opened and wrapped up the history of scientific revolutions. Of course, one may well dispute his assessment of some well-known historical episodes, about which Cohen himself seems not always fully consistent.

Most curious is his endorsement of the view (first stated by Derek Price in 1957) that Copernicus was no revolutionary. It seems odd to minimize the cosmological and epistemological significance of Copernicus; if the Pythagoreans had long preceded him, Newton (with less occasion, we may think) allowed as much with respect to the theory of gravitation, for he thought that the Pythagoreans must have understood this also. No greater tribute could be paid to Copernicus than that implied in Newton's conclusion to the first Scholium of *Principia Mathematica* (1687): I wrote the following treatise, he declared, with the object of elucidating true motions and causes in nature from apparent causes and effects, and conversely of elucidating causes and effects from both true and apparent motions. If Copernicus had not proposed this problem, who did?

The Newtonian system without Copernicus as the first of the "giants" is indeed inconceivable. Bernard Cohen's difficulty arises from the perhaps inavoidable confusion between the idea of revolution as the work of an individual (Lenin, Lavoisier) and the idea of revolution as the fruition of a movement (bolshevism, pneumatic chemistry). Sometimes Cohen seems virtually to be defending the "great man" concept of change, or even (in his discussion of Wegener) the "neglected genius". More frequently, he seems to mark the great men on a scale of revolutionary activity or fervour: thus Bacon's great contribution to methodology "did not constitute a revolution in *science*"; Gilbert "did not establish a new science", unlike Galileo, "a heroic figure of the Scientific Revolution", although even "Galileo's revolution was not complete". Descartes's revolution "did not last" and "it seems clear there was no Keplerian revolution in science before 1687". One remembers that Alfred was a Good King. What is historically important is an understanding of how the separate, even disparate, endeavours of individuals contemporaneous with each other or in quick succession, culminate in some particularly noteworthy and well-founded shift in our vision of nature, for few historians believe that scientific revolutions are literally effected single-handed by a unique scientist. And so to me, for example, it makes good sense to speak of a "revolution in geology" between about 1790 and 1840, whereas talk of a "Lyellian revolution" would be unjustifiable. Or again, it is more constructive to consider the triumvirate Faraday–Maxwell–Hertz as a movement, than to try to weigh out the praise for innovation due to each.

Like many large historical works, Bernard Cohen's book excels as a quarry, rather than as a coherent argument. He is likely to have the last word for a long time to come. □

A. Rupert Hall is Emeritus Professor of the History of Science and Technology at the University of London.

Agents of change

S. Venitt

Chemical Carcinogens, 2nd Edn. ACS Monograph 182.
Edited by Charles E. Searle.
American Chemical Society: 1984. Pp. 1,373. $129.95 (North America), $155.95 (elsewhere).

UNTIL recently, the study of carcinogenesis has been largely correlative and phenomenological. What does chemical A do to biological systems X, Y and Z? Does B do it better and is it metabolized to C? What happens when you apply A before B, or B before A, or mix A and B together? And so forth. This approach has been very fruitful: we now know, for example, that most carcinogens are genotoxic and that most non-carcinogens are not; that many carcinogens are themselves electrophiles or are metabolized to electrophiles; that some substances "promote" tumours but do not initiate them; that many carcinogens are organotropic; and that carcinogenesis is a multi-step process. Much of this information was gathered together in the first edition of *Chemical Carcinogens*, published in 1976.

The study of the mechanism of carcinogenesis was transformed and became at once both analytical and synthetic when two groups independently showed that NIH-3T3 cells could be transformed *in vitro* by transfection with DNA from a human bladder tumour, and that a single base change within a proto-oncogene was in some cases sufficient to activate the oncogene. There has followed a flood of research (which shows no sign of abating) which stresses the importance of both point mutation and chromosomal rearrangement in the activation of proto-oncogenes. The idea that DNA is the critical target for carcinogens has thus gained support from two different streams: the older, painstaking, sometimes stumbling correlative approach, and the rather more breezy and with-it analytical methods of cell biology and recombinant DNA technology.

Nevertheless, "descriptive chemical carcinogenesis" will not go away. We still need to know whether chemicals, new or already in use, are likely to be carcinogenic. In this light appears the second edition of the American Chemical Society's *Chemical Carcinogens*, which offers an expanded view of the descriptive approach embodied in the first edition.

ACS *Chemical Monographs* are intended to serve two main functions: (i) "to make available to chemists a thorough treatment of a selected area in form usable by persons working in more or less unrelated fields to the end that they may correlate their own work with a larger area of physical science"; and (ii) "to stimulate further research in the specific field treated". The first edition filled these roles admirably, not only for chemists, but also for a wider audience interested in chemical carcinogenesis. This second edition, in two well-indexed and richly-referenced volumes, is a valuable update and expansion: there are now 22 chapters (all by leading specialists in each field) instead of 16.

Included are completely new chapters on cancer epidemiology, DNA–carcinogen–metabolite interactions, halogenated organic compounds, inorganic carcinogens, environmental *N*-nitroso carcinogens, triazenes, hydrazines, azo and azoxy compounds, aflatoxins, fusarial mycotoxins, carcinogenic medicines, and the inhibition of chemical carcinogenesis. Other topics which were covered in separate contributions in the first edition (for example, metabolism of carcinogens, carcinogens in plants and microorganisms) are now spread over several. Although much of the core of the first edition remains (polynuclear aromatic hydrocarbons; soots, tars and oils; aromatic amines and their epidemiology; laboratory hazards; alkylating agents; mineral fibres; *N*-nitroso compounds; bracken carcinogens; carcinogens in food; bioassays and short-term tests) several important topics are omitted, such as tumour promotion and co-carcinogenesis, endocrine aspects of carcinogenesis and respiratory carcinogenesis. This is a pity, and it is fair to assume that the vagaries of deadlines and non-availability of authors dictated the final content.

Much of the material consists of detailed and very helpful tabulations of carcinogens and descriptions of their metabolism and biological activity, with much emphasis on structure–activity relationships. In a text of this size and scope there are bound to be some contributions which are more thorough or more readable than others and it is tempting to give each of them marks out of ten. Although I have resisted the urge I must nevertheless single out Lawley's contribution on carcinogenesis by alkylating agents as the chapter which gives the deepest and broadest view of chemical carcinogenesis as it stood in 1981–1982. Viewing alkylating agents as "archetypal carcinogens", he provides us with a masterly, wide-ranging review, which includes discussions of chemical reactivity, dose–response relationships, mechanisms of mutagenicity, short-term tests, DNA repair, models of carcinogenesis, alkylating agents and human cancer — and, as a final flourish, squeezes in (in a note added in proof) a short account of the first reports of activation of proto-oncogenes by point mutation.

Orchestrating such an encyclopaedic text must have been an awesome task. The editor, Dr C.E. Searle, must be congratulated for producing such a useful revision of an already indispensable work. □

S. Venitt is a member of the Section of Chemical Carcinogenesis, Institute of Cancer Research, Royal Cancer Hospital, Sutton, Surrey.

ANNOUNCING

MIRDAB

MICROBIOLOGICAL RESOURCE DATABANK

CATALOG 1/1985

This first printed edition of MIRDAB contains a total of 601 records of animal cells (general, genetic mutants and hybridomas), plant cells and animal viruses. The information is highly structured to provide specific and relevant data on the cell or virus, its source and availability and an entry to the published scientific literature. Computerization of the data, with a view to future on-line availability when the critical mass warrants it, has enabled the convenient production of an ordered body of information along with two indexes to facilitate rapid retrieval even in the printed catalog.

CONTENTS OF CATALOG 1/1985

1. CELL AND VIRUS LINES
- Animal cells – general
- Animal cells – genetic mutants
- Animal cells – hybridomas
- Plant cells
- Animal viruses

2. INDEXES
- Cell/virus name index
- Application index

Entries within each category of cell or virus line have been ordered and indexed to simplify the task of locating cell lines or viruses that meet the user's needs. To find entries of potential interest, all that the user has to do is to page through the catalogue, keeping in mind the sorting rules which determine the order of appearance of records within each category, or to refer to one of the indexes at the back of the catalogue.

There are two indexes in the catalog:

1. A consolidated cell/virus name index
This is derived from the abbreviated cell or virus name, or from the cell line code of each cell or virus line.

2. An applications index
This index is divided into two major categories – animal cell applications and plant cell applications. Each group is subdivided as follows:

Animal cell applications
These are split into six types: **Assays, Diagnosis, Products** and **Toxicology** (all from Animal cells – general), **Diseases/disorders** (for genetic mutant cells) and applications on **Antigen specificity** (for the hybridomas). The names of diseases and disorders are combined into one sub-index since, for some Genetic mutant cells, there is a certain ambiguity as to whether particular syndrome names are "diseases" or "disorders".

Plant cell applications
The three areas covered are:
Crop improvement, Production, and **Miscellaneous applications.**

Editorial Board
The Editorial Board members act as scientific advisers and referees to the data collection.

TISSUE CULTURE AND RETICULOENDOTHELIAL SYSTEM

Edited by P. Röhlich and E. Bácsy

Proceedings of the Joint Congress of the European Tissue Culture Society and the European Reticuloendothelial Society, Budapest, 9–13 May 1983.

One of the fields in which cell culture is broadly applied is in research on the reticuloendothelial system (RES). These Proceedings, which contain results and data on recent advances in the field, will be of interest and value to researchers in cell culture, RES, immunology, cancer research, endocrinology and biochemistry.

Session headings –

- receptors on phagocytic cells
- cell membrane and macromolecular traffic
- various aspects of RES function
- stem cells and differentiation
- monoclonal antibodies
- interferon
- cell culture and malignancy
- endocrine cells in culture
- endothelial cell culture
- plant tissue *in vitro*

An essential guide to successful production

This book provides concise and up-to-date information on vegetable crops grown in tropical regions. It contains details of all the factors affecting growth and a clear explanation of techniques that can be applied to increase the level of production. It will be of use to students, extension service staff and research workers who wish to enlarge their knowledge of the range of food crops available for growing in the tropics.

Vegetables in the Tropics provides full information on the cultivation and environmental requirements of about 140 crops.

Hardcover ISBN *0 333 24266 1* **£35.00**
Paperback ISBN *0 333 24268 8* **£15.00**

Faulting the heavens

David W. Hughes

Under Newton's Shadow: Astronomical Practices in the Seventeenth Century.
By Lesley Murdin.
Adam Hilger: 1985. Pp. 152. £16.75, $26.

WHAT was it like being an astronomer in the Newtonian age (1643–1727)? There is no easy answer to the question as there was in fact only *one* full-time professional and even he, the Reverend John Flamsteed, diverted himself with his parish at Burstow, instrument-making and tide tables. The remainder were scientific generalists who saw little reason to specialize and flitted from subject to subject apparently as the whim took them. Even Edmond Halley, probably next in line for the astronomer appelation, spent only a quarter of his time studying lunar motion, planetary transits, occultations, eclipses, southern stars, proper motion and comets. For the rest he enjoyed the pleasures of meteorology, geomagnetism, physics, pure mathematics, and the editing and translating of ancient mathematical texts, not to mention his duties at various times as a captain in the Royal Navy, a diplomat and the deputy comptroller of the Chester Mint.

The Newtonian age was a time of transition. The pre-Civil-War concept of a magical and mystical world was tackled by men with a desire to avoid speculation and a preference for observation and the accumulation of data. Aristotelian views of a changeless, perfect (and extremely boring) heaven crumbled with the invention and development of telescopic instruments. Astronomers were provided with a goal, the discovery of an easy method of finding the longitude of a ship at sea, and the government were even prepared to spend money to find an answer. In the new Royal Society the scientific generalists found an excellent means of exchanging ideas, meeting like-minded friends and publishing their results. The gap between amateur and professional astronomer was only just beginning to open up. All that was needed was a grammar school education, enthusiasm, a cheap refracting telescope, an altitude measurer and a clock.

Lesley Murdin has tried to introduce us to the sort of men who found astronomy fascinating. The list is mercifully short — Flamsteed, a dozen or so university dons (for example Gregory, Halley, Hooke, Newton, Wallis, Ward, Whiston and Wren) who spent a fraction of their time with stars and planets, another dozen interested amateurs (among them Towneley, Derham, Pound, Gray and Moore) who had also to work for a living, and a final dozen "observatory technicians" (Crosthwait, Denton, Leigh and Sharp, for instance). From this narrow base Murdin has drawn a series of sweeping conclusions. "The number of astronomers who never married seems high and might suggest a general tendency to put work before relationships." Astronomers were independent thinkers and creative but generally had "an interest in objects rather than people" and "found difficulty in cooperating with others". They exhibited "a tendency to solitariness".

At the end of the book I was left with a very sketchy idea of the motivation of astronomers as such, and of their specific problems of learning, observing, calculating, interrelating, publishing, teaching and instrument-making. Little is said about their standing in the community. Murdin has provided us with a readable gallop through the astronomical seventeenth century but one which makes clear that much more work needs to be done in this field. Additionally, the lack of references is frustrating, often leaving the reader with no idea of the provenance of a quotation. An index that only lists proper names also hints at a job half done. □

David W. Hughes is Senior Lecturer in Astronomy and Physics at the University of Sheffield.

Diverse questions

Elvin A. Kabat

The Antibody Enigma.
By Thomas J. Kindt and J. Donald Capra.
Plenum: 1984. Pp. 270. $35, £33.25.

A PERSON wishing to learn about the structural and genetic basis of antibody diversity and antibody specificity might well be overwhelmed by the literature. *The Antibody Enigma* is a good place to start to get to grips with the subject.

The authors do not follow a strictly historical treatment but attempt to present the subject in the light of the working hypotheses considered and discarded as new experimental data became available. As they state in the preface, "*The Antibody Enigma* is a somewhat personal view of the antibody diversity problem from two investigators who have spent the past 18 months trying to penetrate the enigma". Presumably, much of this was done in face-to-face discussion, to formulate points of agreement and resolve differences. I wish I could have listened in. It would have been difficult not to interrupt, however, for despite enormous progress this is an area which is still filled with differences of opinion, of interpretation, and of judgement about the relative weight to be given to the various mechanisms contributing to the vast repertoire of antibody combining sites.

After defining the problem, the authors set down the serologists' and biochemists' approaches to it and their unique features. In subsequent chapters, they analyse "polar", specifically the germ-line versus somatic mutation hypotheses, and the "maverick" solutions (those based on data not in accord with either). This is followed by discussion of the contributions of molecular biology and a final chapter entitled "Antibody Diversity: A Contemporary Solution". Many key references are provided, but the authors often mention individuals by name with no reference and at many points I found it frustrating not to be able to pin down the source of some of the statements.

In the preface, Kindt and Capra apologize if they have "offended anyone by omitting their own contribution. "; given the vastness of the literature they may well have. In line with the general trend among molecular biologists who have established so many ways of generating antibody diversity that they no longer consider how much of this diversity is related to antibody complementarity, the authors do not deal with this question. More understandably, there is no hint of the ferment of activity consequent upon the cloning and sequencing of the T-cell receptor (the book was in press when all the excitement began). But clearly this is a volume that should be read by individuals wishing to enter the field. □

Elvin A. Kabat is Higgins Professor of Microbiology and Professor of Human Genetics and Development at Columbia University.

Growing analysis

Bernard Wood

Size and Scaling in Primate Biology.
Edited by William L. Jungers.
Plenum: 1985. Pp.491. $69.50, £66.

THIS book is about allometry, which, in both the literal and the metaphorical sense, is a growth area. Literally, because it is the study of the effects of an increase in the size of organisms on their shape. Metaphorically, because in recent years allometry has taken over from multivariate morphometrics as one of the main analytical preoccupations of primatologists and hominid palaeontologists.

A system is allometric when a variable (or variables) measuring overall size has more than a random effect on another measure, be it tooth size, gut area or limb length to name but a few of the associations discussed in the book. Various contributors try to classify allometric studies, but they can be broadly divided into three categories. The first, which I shall call "organism-based", and which includes ontogenetic and intraspecific allometry, deals with the effect of size on the shape of an organism while holding functional and ecological variables partly, or wholly, constant. The second category is "system-based". In this approach groups of organisms are used as tools to investigate the influence of size on function and ecological context. Such studies are usually broad and interspecific, and include the analysis of grade shifts; that is, changes in the intercept as well as differences in the slopes. Research of the third category makes use of the empirical observation that variables are correlated to predict one variable from another. Often this stands on its head the notion of a "dependent" and an "independent" variable, for what is usually regarded as independent (body size, for example) is often predicted from dependent variables such as tooth size. This final method is applied most often in palaeontological studies which are perforce based on fragmentary material and may use ontogenetic, intraspecific or interspecific associations.

The twin aims of the book are to assess past progress in allometric work and to review the future prospects. Several of the contributors discuss the role of allometry in evolutionary change. Is evolution simply the transposition of the derived form to a position up or down the ontogenetic slope (Shea; Cochard), or is it more than one process — perhaps "short term", involving relatively simple adjustments of growth, and "long term", involving adjustments of function and grade, and perhaps dictated by general metabolic constraints (Martin and Harvey; Ford and Corruccini)? Although not always in agreement with him, I especially enjoyed Shea's contribution. His work on ontogenetic allometry is stimulating, but even though my prejudices about the pattern of hominid evolution are reinforced by the findings of his excursion into that minefield, I remain unconvinced that ontogenetic allometry "explains" all evolutionary change. Lande provides a much needed genetic perspective on allometry, and Leutenegger and Cheverud's account of the effect of size on sexual dimorphism in primates is both an analytically ingenious and intellectually rigorous attempt to understand the mechanism of the strong positive allometry that is seen in sexually dimorphic species.

A number of the chapters provide overviews of particular systems — Martin *et al.* on the gut, Jungers on the skeleton, Larson on organ weights, and Gingerich and Smith on dentition. Hidden within the latter is an admirably concise discussion of the vexed question of line-fitting. This is a point which is addressed by several of the contributors (Martin *et al.*; Wolpoff; Steudel and Ford; Corruccini). Wolpoff takes an admirable, but misguided, swim against the tide of consensus. The majority vote of the contributors is against him. Least squares regression is a technique best reserved for prediction, with association being best studied by the major axis technique, or by one of its variations. Smith and Steudel each address the problem of using apparent empirical allometric associations between variables to predict body size in fossil taxa, with Smith tackling *Gigantopithecus* and Steudel the fossil hominids. They both advocate what Smith has described as the "narrow" allometric approach, but differ in their attitude towards the advisability of averaging the results of several attempts to estimate size. I side with Smith on this; the average of three poor estimates is not likely to provide a good one.

The remaining contributions include investigations of the influence of size on limb design (Preuschoft and Demes; McNeill Alexander), energetics (Heglund) and polygyny (in which Clutton-Brock rightly criticizes others for offering circular arguments to explain sexual dimorphism and polygyny, and then proceeds to offer another himself!). Bookstein contributes a paper on how to measure shape change and Fleagle furnishes a general review of allometry. Finally, Armstrong provides an excellent review of the relationships, causal or otherwise, between body size and brain size and structure.

Jungers is to be congratulated on his editorial efforts. The 20 contributions necessarily vary in scope, quality and novelty, but are uniform in style and layout, and remarkably free of typographical errors. Altogether this is a suitable volume to mark the coming of age of primate allometry, and it is only three years late to mark the golden jubilee of Huxley's seminal book on relative growth. □

Clinical exchange

Robert Walgate

Harrap's French and English Science Dictionary.
Harrap: 1985. Pp.302. £17.50.

IN 1982, when socialism was the rage again in France, the French became passionate about protecting their language "as a language of science". The then minister of research even established a priority action, a *programme mobilisateur*, to that end, and launched an ambitious plan for a great new French-language encyclopaedia to embrace all knowledge, as the encyclopaedists of the eighteenth century had done before him. Heady days! The programme and the encyclopaedia project still exist, but somehow the passion has gone. The encyclopaedia has had difficulty finding a publisher. French scientists speak English at international conferences in France, against a ministerial directive. And the preferred language of publication, for anyone wishing to be heard outside France, is still English.

Nevertheless a considerable amount of good science still appears only in French — for example in the *Comptes Rendus* — and the publication of a new French–English (and English–French) science dictionary is an event of some interest.

However, the readership of the dictionary may be more limited than Harrap's expect. The book includes relatively few technical terms in the physical as opposed to the medical and biological sciences (with their naming of parts, and organisms and maladies), and since the translations of the physical terms are often self-evident (astronomy — *astronomie*), this dictionary will prove of real help mostly to biologists and clinical scientists. Picking a page at random confirms this impression: out of 50 definitions nearly half are in biology, zoology or medicine; 15 per cent in physics, chemistry and astronomy; 15 per cent in geology and oceanography; and the rest are general terms. As further examples, the book offers no translation of "hadron" or "lepton", and classifies "neutrino" as a biological term; includes "geode" but not "geoid"; and seems not to have heard of the "magnetosphere" or a "white dwarf". Nevertheless with much French clinical science in particular still published in French, this dictionary will find a role in easing the two-way traffic between English-speaking biologists and clinical scientists and their French counterparts. □

ACADEMIC PRESS

USE OF TISSUE CULTURE AND PROTOPLASTS IN PLANT PATHOLOGY

Edited by John P. Helgeson and B.J. Deverall

A Publication of Academic Press Australia

In recent years many procedures have become available for the culture of plant cells as calli and dispersed cells and for the isolation of viable protoplasts In plant pathology these procedures can be used both as aids in analysing parasite-plant interactions and as methods for producing improved plants

This book describes ways in which tissue cultures and protoplasts from plants have been and can be used in fundamental and applied research in plant pathology and is intended for university teachers and their advanced students and research workers in plant pathology and botany and for all those at the interfaces of plant pathology, genetics and breeding

ISBN 0-12-338650-0, 1983, 208 pp., $25 00 / £20 00 (U K only)

METHODS IN ENZYMOLOGY Volume 58 Cell Culture

Edited by William B Jakoby and Ira H Pastan

CONTENTS (Section Headings):

Basic Methods Laboratory Requirements and Media, General Cell Culture Techniques.
Specialized Techniques Metabolism, Genetics, Hybridization and Transformation,
Virus Preparations Specific Cell Lines.

ISBN 0-12-181958-2, 1979, 642 pp , $69.50 / £56 00 (U K only)

ADVANCES IN CELL CULTURE Volume 4

Edited by Karl Maramorosch

The advances described by the contributors to this volume will be indispensable to research workers, teachers, and students who use animal, plant or invertebrate cells in bioengineering, pathology, microbiology, virology, genetics, parasitology, insect pathology and physiology and in cell biology studies

CONTENTS:

A.F Miranda, T Mongini, and S DiMauro, Human Myopathies in Muscle Culture Morphological, Cytochemical, and Biochemical Studies *L.P Rutzky,* The Biology of Human Colon Tumor Cells in Culture *C.A. Heckman,* Cell Shape and Growth Control *P.J. Price,* Hybridoma Technology *W Liebrich, K.H Glatzer, and N Kociok,* Morphogenesis of Mitochondria during Spermiogenesis in *Drosophila* Organ Culture *J -M Quiot, A. Vey, and C Vago,* Effects of Mycotoxins on Invertebrate Cells *in Vitro S Reuveny,* Microcarriers in Cell Culture Structure and Applications *A. Leibovitz,* The Establishment of Cell Lines from Human Solid Tumors Each chapter includes references Index

PRINCIPLES OF METASTASIS

Leonard Weiss

FROM THE PREFACE: The purpose of this book is to describe the various components of the metastatic process in pathologic sequence and to discuss the underlying principles The fact that in this book metastasis has been divided into a number of steps and phases, each of which for convenience occupies a separate chapter, may at first sight give the impression that these events are discrete and independent This impression would be misleading, because as emphasized throughout, some common and interactive processes and mechanisms recur throughout the metastatic cascade In order to emphasize this, overlaps of content have been made in some of the chapters in which basically the same observations are examined in different ways

ISBN 0-12-742820-8, May 1985, 416 pp , $52 00 / £52 00 (U K only)

Applied Industrial Catalysis, Vol. 3. BRUCE E. LEACH (ed.) *Academic· 1984. Pp 397. ISBN 0-12-440203-8. $69.50, £53.*

Automated Stream Analysis for Process Control, Vol. 2. DAN P MANKA (ed). *Academic· 1984. Pp. 205. ISBN 0-12-469002-5. $59, £41.50.*

Calculating Instruments and Machines. By DOUGLAS R. HARTREE *MIT Press. 1984. Pp. 138. ISBN 0-262-08147-4. £31.25.*

Ergonomic Data for Equipment Design. HEINZ SCHMIDTKE (ed.) *Plenum: 1984. Pp. 284 ISBN 0-306-41893-2. Np.*

Signal Recovery from Noise in Electronic Instrumentation. T.H. WILMSHURST *Adam Hilger· 1985. Pp 193 ISBN 0-85274-783-7. Hbk £17.50, $28*

Technological Risk Assessment, No. 81. P.F RICCI *et al.* (eds) *Nijhoff· 1984. Pp. 363 ISBN 90-247-2961-0 Dfl. 125, $48, £32*

Wind Energy Conversion. Proceedings of the 1984 Sixth BWEA Wind Energy Conference. PETER MUSGROVE (ed.). *Cambridge University Press· 1984 Pp 464. ISBN 0-521-26899-0 £30, $59.50*

Environmental Sciences

Airborne Sulphur Pollution: Effects and Control. *HMSO: 1985 Pp. 265. £18.05*

Ecology, Impact Assessment, and Environmental Planning. By WALTER E WESTMAN. *Wiley: 1985 Pp. 532 Pbk ISBN 0-471-80895-4. Pbk £40.40.*

The Effects of SO_2 on a Grassland: A Case Study in the Northern Great Plains of the United States. W.K. LAUENROTH and ERIC M PRESTON (eds) *Springer-Verlag· 1984. Pp. 207. ISBN 3-540-90943-5/ 0-387-90943-5 DM 88, $32.90.*

Earth Sciences

California Landscape: Origin and Evolution. By MARY HILL. *University of California Press 1985. Pp. 262. ISBN 0-520-04831-8. $19 95.*

Deserts and Arid Lands. FAROUK EL-BAZ (ed.) *Martinus Nijhoff· 1984. Pp. 222. ISBN 90-247-2850-9. Dfl 115, $46*

The Estuary as a Filter. VICTOR S. KENNEDY (ed.). *Academic. 1984. Pp. 511 ISBN 0-12-405070-0. $39.50, £30.50.*

Field Guide to Soils and the Environment: Applications of Soil Surveys. By GERALD W. OLSON *Chapman & Hall: 1985. Pp. 217. ISBN 0-412-25970-2 Pbk £12.95, $49*

Geochemistry of Organic Matter in the Ocean. By EVGENII A. ROMANKEVICH *Springer-Verlag: 1984 Pp. 334. ISBN 3-540-12754-2. DM 148*

The Mangrove Ecosystem: Research Methods. SAMUEL C. SNEDAKER and JANE G SNEDAKER (eds) *UNESCO 1984. Pp 251 ISBN 92-3-102181-8. Np.*

Problems and Methods for Lithospheric Exploration. ROBERTO CASSINIS (ed) *Plenum. 1984. Pp. 222. ISBN 0-306-41721-9 Np.*

The Story of the Earth. By PETER CATTERMOLE and PATRICK MOORE *Cambridge University Press. 1585. Pp 224. ISBN 0-521-26292-5. Np*

Volcanic Hazards. By R J. BLONG. *Academic. 1984. Pp 424. ISBN 0-12-107180-4.$66.£49 50.*

Wind as a Geological Process. By RONALD GREELY and JAMES D. IVERSEN *Cambridge University Press: 1985. Pp 333. ISBN 0-521-24385-8. £35, $59 50*

World Climatic Systems. JOHN G. LOCKWOOD. *Edward Arnold· 1985. Pp 292. ISBN 0-7131-6404-2. £17.50.*

Applied Biological Sciences

Advances in Biochemical Engineering/Biotechnology. A. FIECHTER (ed) *Springer-Verlag· 1984 Pp 202 ISBN 3-540-13539-1/0-387-13539-1 DM 106, $38 60*

Asthma: Physiology, Immunopharmacology and Treatment. A. BARRY KAY, K. FRANK AUSTEN and LAWRENCE M. LICHTENSTEIN (eds) *Academic 1984. ISBN 0-12-402750-4 $79, £49.*

Cancer Chemotherapy and Selective Drug Development. K R HARRAP, W DAVIS and A H CALVERT (eds) *Martinus Nijhoff 1984 Pp. 585 ISBN 0-89838-673-X. Dfl 178, $52.50, £36.95*

Carcinogenesis and Mutagenesis Testing. J F DOUGLAS (ed.). *Humana: 1984 Pp 335 ISBN 0-89603-042-3 $49.50*

Clinical Biochemistry: Contemporary Theories and Techniques. HERBERT E. SPIEGEL (ed). *Academic· 1983 Pp 271 ISBN 0-12-657103-1 $42, £32 50*
